

**Photoaktivierungsfähige Rhodamine als Bio-Calcium-Sensoren
und Markierungen für Tetracystein-Tags in Proteinen**

DISSERTATION

zur Erlangung des mathematisch-naturwissenschaftlichen Doktorgrades
"Doctor rerum naturalium"
der Georg-August-Universität Göttingen

vorgelegt von

Sergey Yan

aus Leningrad (UdSSR)

Göttingen, 2010

Referent: Prof. Dr. Armin de Meijere

Korreferent: Prof. Dr. Stefan W. Hell

Tag der mündlichen Prüfung: 28. Januar 2011

Die vorliegende Arbeit wurde in der Zeit von September 2006 bis November 2010 im Max-Planck-Institut für biophysikalische Chemie in Göttingen angefertigt.

Hiermit möchte ich für die Überlassung des interessanten Themas und große Unterstützung während meiner Promotionszeit Herrn Prof. Dr. Armin de Meijere, Herrn Prof. Dr. Stefan W. Hell und Herrn Dr. Vladimir N. Belov ganz herzlich danken.

to my family

Table of Contents

| | |
|---|-----------|
| Abbreviations..... | 7 |
| Preface..... | 10 |
| Chapter 1. Fluorescent Ca²⁺ sensors for imaging calcium distributions in biomatter | 13 |
| 1. Fluorescence and principles of fluorescence microscopy..... | 13 |
| 2. Fluorescent indicators for calcium cations..... | 18 |
| 2.1. Main photophysical principles of ion sensing by fluorescent indicators and determination of calcium concentrations from the spectroscopic data..... | 18 |
| 2.2. Diverse coordination moieties in fluorescent Ca ²⁺ indicators | 21 |
| 2.3. Early steps in the creation of highly sensitive fluorescent calcium indicators for biological purposes | 22 |
| 2.4. BAPTA and its derivatives | 25 |
| 2.5. APTRA and its derivatives | 48 |
| 2.6. Crown-based calcium indicators..... | 51 |
| 2.7. Calixarene hosts as coordination moieties for calcium sensors..... | 58 |
| 2.8. Podands as a coordination moiety for calcium sensors | 60 |
| Chapter 2. Synthesis and properties of new fluorescent calcium sensors..... | 63 |
| 1. Search for an optimal coordinative part and its position within the phenylxanthene backbone..... | 63 |
| 2. Model compounds..... | 70 |
| 2.1. Spectroscopic properties of the model compounds..... | 73 |
| 3. Synthesis of rhodole derivatives with a crown-ether moiety fused with the xanthene fragment..... | 75 |
| 3.1. Synthesis of the phenol building blocks via the unfunctionalized crown ether..... | 75 |
| 3.2. Attempted synthesis of phenol building blocks via the crown ether prepared from 2-amino-4-nitrophenol | 76 |
| 3.3. Synthesis of the phenol building blocks by a ring-closing reaction of a tetraethylene glycol precursor..... | 77 |
| 3.4. Spectroscopic properties of the target compounds in the presence of Ca ²⁺ ions ... | 82 |
| 4. Synthesis of <i>N, N, N', N'</i>-tetramethylrhodamine (TMR) derivatives with an azacrown-ether ring fused with the 9-(2-carboxy)phenyl ring | 99 |
| 4.1. Synthesis via the initial formation of TMR derivatives..... | 100 |
| 4.2. Elaboration of a route to phthalic acid derivatives with an azacrown-ether fused to the aromatic ring | 103 |

| | |
|---|------------|
| Chapter 3. Synthesis of SplAsH-based fluorescent labels for tetracysteine tags and their bioimaging tests..... | 110 |
| 1. Development of biarsenical probes | 110 |
| 2. Synthesis of precursors for SplAsH-based fluorescent labels | 118 |
| 3. Synthesis of reactive fluorescent labels..... | 122 |
| 3.1. Synthesis of the water-soluble labels | 122 |
| 3.2. Synthesis of the TMR derivative intended for the localization of the tagged proteins in mitochondria | 123 |
| 4. Spectroscopic control of the prepared biarsenical probes..... | 124 |
| 5. Bioimaging tests of the prepared biarsenical probes | 127 |
| Experimental Part..... | 135 |
| 1. General Remarks | 135 |
| 2. Preparation of Known Compounds | 136 |
| 3. Experimental procedures..... | 138 |
| Summary | 165 |
| References..... | 169 |
| Spectral Data..... | 177 |

Abbreviations

| | |
|---------------------------------|---|
| Ac ₂ O | acetic anhydride; |
| AcCl | acetyl chloride; |
| AcOH | acetic acid; |
| Amino acid residues: | |
| P | proline; |
| G | glycine; |
| S | serine; |
| C | cysteine; |
| APTRA | 2-aminophenoxy- <i>N,N,N'</i> -triacetic acid; |
| BAPTA | 1,2-bis(<i>o</i> -aminophenoxy)ethane- <i>N,N,N',N'</i> -tetraacetic acid; |
| BnCl | benzyl chloride; |
| BODIPY | 4,4-difluoro-4-bora-3a,4a-diaza- <i>s</i> -indacene; |
| BuCN | valeronitrile; |
| C ₁₀ H ₈ | naphthalene; |
| dba | dibenzylideneacetone; |
| DBU | 1,8-diazabicyclo[5.4.0]undec-7-ene; |
| DIPEA | <i>N,N</i> -diisopropylethylamine; |
| DMAA | <i>N,N</i> -dimethylacetamide; |
| DMAP | 4-(<i>N,N</i> -dimethylamino)pyridine; |
| DME | 1,2-dimethoxyethane; |
| DMF | <i>N,N</i> -dimethylformamide; |
| DMSO | dimethylsulfoxide; |
| EDC | 1-[3-(dimethylamino)propyl]-3-ethylcarbodiimide; |
| EDTA | <i>N,N, N', N'</i> -ethylenediamine tetraacetate; |
| ESIPT | excited state intramolecular proton transfer; |
| Et ₂ SO ₄ | diethylsulfate; |

| | |
|--|---|
| EtOAc | ethyl acetate; |
| FlAsH | <u>fluorescein</u> <u>arsenic</u> <u>hairpin</u> binder; |
| FRET | fluorescence resonance energy transfer; |
| GFP | green fluorescent protein; |
| HMPTA | hexamethylphosphortriamide; |
| HOMO | highest occupied molecular orbital; |
| ICT | intramolecular charge transfer; |
| <i>i</i> PrOH | 2-propanol, |
| ISC | inter system crossing; |
| LUMO | lowest unoccupied molecular orbital; |
| MeCN | acetonitrile; |
| MeNH ₂ | methylamine; |
| MES | 2-mercaptoethanesulfonic acid; |
| MLCT | metal-to-ligand charge transfer; |
| MsCl | methanesulfonyl chloride; |
| <i>n</i> -BuOH | 1-butanol; |
| NHS | <i>N</i> -hydroxysuccinimidyl; |
| PALM | <u>photo</u> <u>activated</u> <u>localization</u> <u>microscopy</u> ; |
| PBS | phosphate-buffered saline; |
| PCT | photo charge transfer; |
| PET | photo electron transfer; |
| PFA | polyformaldehyde; |
| <i>p</i> -TosOH•H ₂ O or TsOH•H ₂ O | <i>para</i> -toluene sulfonic acid monohydrate; |
| Py | pyridine; |
| SDS-PAGE | <u>dodecyl</u> <u>sulfate</u> <u>polyacrylamide</u> <u>gel</u> <u>electrophoresis</u> ; |
| SplAsH | <u>spiro</u> <u>lactam</u> <u>arsenic</u> <u>hairpin</u> binder; |

| STED | stimulated emission depletion; |
| TAPD | tetraalkyl <i>p</i> -phenylenediamine; |
| <i>t</i> -BuOK | potassium <i>tert</i> -butylate; |
| <i>t</i> -BuONa | sodium <i>tert</i> -butylate; |
| TCEP | tris(2-carboxyethyl)phosphine; |
| TFA | trifluoroacetic acid; |
| THF | tetrahydrofuran; |
| TMR | tetramethyl rhodamine; |
| TMSCl | trimethylsilyl chloride; |
| TMSI | trimethylsilyl iodide; |
| TrCl | chlorotriphenylmethane; |
| Triton – X100 | 4-(1,1,3,3-tetramethylbutyl)phenyl-polyethylene glycol; |
| TsCl | <i>para</i> -toluene sulfonyl chloride; |
| TSTU | <i>N,N,N',N'</i> -tetramethyl- <i>O</i> -(<i>N</i> -succinimidyl)uronium tetrafluoroborate; |
| Z | benzyloxycarbonyl. |

Preface

Cells and their organelles are the main objects of biological research. The problem of the low natural contrast of the microscopic cell images was noted long ago. Most of the cell compartments have weak colors, and they and other objects inside cells could not easily be distinguished. Hundreds of staining procedures have been developed since the middle of the 19th century.^[1] Most of them are based on the local introduction of dyes into the cell components. Initial dyes were non-fluorescent and they selectively marked the required cell compartments by the interaction with the cell components without covalent binding. Nowadays, modern fluorescent labels are represented by the genetically encoded proteins,^[2] or adducts of the fluorescent dyes with small molecules (recognizable units) which react with genetically encoded tags.^[3] Within this great set of available labelling reagents, there are not only fluorescent compounds for imaging but also molecular probes which provide valuable information on the actually occurring events in cells, e. g. ion-channels opening or closing, protein polymerization or depolymerization, signal transduction, protein synthesis and so on. One kind of molecular probes – fluorescent calcium indicators – play a very important role in studying the calcium distribution and dynamics in various biological objects and processes.

The first part of this work deals with the design and synthesis of calcium indicators

Figure 1. The first group of Ca^{2+} indicators prepared in this work (the red dashed line marks the fluorophore moiety, the blue dashed line – ionophore moiety), $\text{R} = \text{H}, \text{Et}, \text{CH}_2\text{COOH}$.

small organic dye molecules are more photostable (especially xanthenes), and their chemistry is well developed.

For reasons of its good spectroscopic properties, rhodol (3-amino-6-hydroxy-9-phenylxanthene) was chosen as a fluorophore moiety for the first group of indicators (see Figure 1). The coordinative element of these sensors was realized in the form of an azacrown ether with a suitable cavity for calcium cations. Another key fragment of a new indicator is

(sensors). There are two kinds of the new calcium probes: genetically encoded calcium-sensitive proteins (most of them originate from aequorin^[4]) and indicators, based on fluorescent organic dyes. Calcium-sensitive proteins have significant drawbacks: their molecular weight is about 27 kDa, and they may perturb the parent protein. Moreover, they have a low photostability and a limited range of “working” wavelengths. On the other hand,

the carboxy group in the *ortho*-position of a phenyl ring attached to rhodol. It can provide a photoswitching ability of this dye (e. g. by creating a photosensitive spiroamide^[5] or spirodiazoketone^[6]) which may be an important requirement for PALM (photoactivated localization microscopy) method.

The first target group of indicators (Figure 1) was prepared in 13–15 steps. The spectroscopic properties of the new sensors have been established, and their applicability in the role of indicators for calcium was evaluated.

Another group of the target sensors is depicted in Figure 2. In them, the crown ether ring is fused with the phenyl group at C-9 of the xanthene residue, and the chromophore has been changed to rhodamine. The tetramethylrhodamine backbone was envisaged in order to increase the membrane permeability of the fluorophore.

Figure 2. The second target group of sensors (the red dashed line marks the fluorophore moiety, the blue dashed line – ionophore moiety), R = Et, CH₂COOH.

Figure 3. Adducts of SplAsH with the xanthene dyes, applied for the labeling.

The second part of this work deals with an attempt of the selective labelling of peptides and proteins with fluorescent dyes. For this, three adducts of the so-called SplAsH^[7] with NHS esters of the “open” and “closed” isomers of Rhodamine S^[8] amides and NHS esters of TAMRA^[9] were prepared (Figure 3). The binding properties of the compounds SplAsH-RhS-OF, SplAsH-RhS-CF, SplAsH-TAMRA were studied by spectroscopic and biological tests.

Chapter 1. Fluorescent Ca^{2+} sensors for imaging calcium distributions in biomatter

1. Fluorescence and principles of fluorescence microscopy

In the XVIth century, the Spanish physician Nicolas Monardes discovered the phenomenon of fluorescence,^[10] and since that time, there is an ever increasing interest in this process, the expression of which was coined by G. Stokes,^[11] (Scheme 1).

Scheme 1. Energy levels of a molecule and electronic transitions between them caused by the interaction with light (ISC – Inter System Crossing).

Being exposed to light, molecules may be excited from the ground electronic state (S_0) to the first excited state (S_1). After that, the molecule can emit the photon of the longer wavelength and return to the ground state S_0 . This process is called fluorescence. However, the molecule can return to the ground state (S_0) not only directly, but also via a triplet state (T_1). These transitions ($S_1 \rightarrow T_1 \rightarrow S_0$ or $S_1 \rightarrow T_1 \rightarrow S_1 \rightarrow S_0$) are called phosphorescence or delayed fluorescence. The processes without light emission, for example, internal conversion or energy transfer may also occur. Other possible processes in the excited state are conformational change, proton transfer, electron transfer, chemical reaction or excimer (exciplex) formation. From these abundant post-excitation changes, only three radiative transitions (fluorescence, phosphorescence and delayed fluorescence) may give an immediate physical response (in the form of light) on the presence of other molecules in the medium, because the energy of all electronic states (S_n , T_n) directly depend on the surrounding of the fluorescent probe. The spectral analysis of the emitted light may provide data on the environment of a fluorescent probe. The fluorescence is the most straightforward process that can be used as an effective analytical tool. Typical parameters of the medium, which can affect the fluorescence, are the polarity, the presence of ions and quenchers, hydrogen bonds, pH, pressure, viscosity, temperature and electrical potential.

As it concerns the detection of “foreign” molecules in the medium, the fluorescence played a very important role in the development of microscopy. The light generates the picture on the retina (or a detector matrix). By that, there is no difference, whether reflected or emitted light is used for imaging. Reflected light is used in conventional optical microscopy, and emitted light – in fluorescence microscopy, which started to emerge since the beginning of the 20th century.^[12] As early as 1930 the first fluorescence microscope was produced by Carl Zeiss.

Microscopy helps one to observe very small objects. But what are the limits of this method? Such kind of questions arose more than one century ago. The diffraction limit for optical microscopy was found by Ernst Abbe.^[13] He established that an optical microscope cannot resolve objects that are separated by the distance which is less than one half of the wavelength of the light used. Abbe’s law can be mathematically expressed as follows: $d = \lambda / (2n \sin \alpha)$ (1), in which d is a minimal distance between the two resolved objects in nm, λ the wavelength of the used light, n the refractive index of the medium, α the aperture angle of the lens. The diffraction barrier was considered to be an absolute limitation and could not be overcome for more than a century. Only in 1994 did, the publication of S. W. Hell and J. Wichmann^[14] reveal the possibility to break the diffraction limit. The general concept of the high-resolved imaging was formulated by S. Hell in 2004.^[15] This concept is applicable to the fluorescence microscopy, where the objects are labelled with fluorescent markers. Thus, the light emitted from these markers forms an image. The optical resolution can be improved by spatial contraction of the imaged fluorescent area applying a special doughnut-shaped laser beam that depletes the population of the excited electronic state. This nanoscopic method is called stimulated emission depletion (STED).^[16] The quantitative description of the STED method is expressed by the following equation.

$$d = \frac{\lambda}{2n \sin \alpha \sqrt{1 + I_{\max}/I_s}} \quad (2)$$

Here, I_s stands for saturation intensity (the light intensity which makes the populations of the ground and the (first) excited states to be equal), I_{\max} for the applied intensity of the STED beam, for the definitions of λ , n and α , see eq. 1.

Scheme 2. The principle of STED microscopy. Red-marked “A”-molecules are the molecules of a fluorescent marker in the ground state S_0 , blue-marked “B”-molecules are the molecules of a fluorescent marker in the first excited state S_1 ; ν_1 is the frequency of excitation light, ν_{STED} the frequency of the doughnut-shaped STED beam; the green doughnut represents the area, where the excited molecules were depleted by the STED beam.

To understand, how the fluorescent area in the STED microscopy can be reduced, one should consider the two states of a fluorescent marker: the initial “dark” state **A**, and the “bright” (excited) state **B**. The excitation by the laser beam applied to the small area of the fluorescent markers converts them from the state **A** into the state **B**. If the molecules in this area are allowed to return back from the excited state **B** into the state **A** spontaneously, then a blurred diffraction-limited image on the detector will be obtained. On the other hand, if the **B**-state zone is immediately illuminated with a second, doughnut-shaped laser beam, all **B**-state molecules are converted into the initial state **A**, with the exception of a small area in the center of the **B**-state zone. Then the molecules from this area will emit light which will be recorded by the detector. The size of this fluorescent area is given by equation (2). Thus, in principle, the attained resolution may be increased to be “infinite”; however, at huge of light intensities the fluorescent markers bleach.

There is another nanoscopic method called “PALM” (PhotoActivation Localization Microscopy).^[17] In the PALM method, also two states of the marker are used. State **A** is non-

fluorescent, and state **B** is fluorescent. With light of low power, the single marker molecules are converted from the non-fluorescent state **A** into the fluorescent state **B**. In order to determine the positions of single molecules, it is necessary to collect emitted photons. The positions of single molecules can be calculated with a localization precision of $x = FWHM/\sqrt{N}$, where FWHM (full width at half-maximum) is a device constant (typically ≈ 300 nm), and N the number of collected photons.

The general concept of optical nanoscopy may be formulated as follows. The objects, which can (reversibly) be photoswitched between the non-fluorescent state **A** and the fluorescent state **B** (see Figure 4), may be optically resolved by application of the finite intensity of light, if they are situated at a distance greater than d (Equation 2) or x (see above).

Figure 4. Light-induced transition between the “dark” state **A** and the “bright” state **B**.

Up to now, only a very limited number of reports deal with the applications of nanoscopic methods in metal sensing.^[18] As it was already mentioned, it is possible to determine the concentration of many metal ions by measuring the fluorescence signal. Some cations emit light themselves (for example, lanthanides and actinides), and the non-fluorescent metal ions may be detected with the help of organic indicators. For example, the presence and the concentration of calcium cations may be detected by various fluorescent sensors. Calcium plays an important role as a second messenger in various biological processes, such as cell growth, transcriptions (DNA to mRNA), metabolism, exocytosis, muscle contraction, apoptosis and so on.^[19] Therefore, it became very important to find a method for the evaluation of calcium concentrations and the distribution of calcium in living cells. In the 1970s it was only possible to localize calcium ions in cells either by precipitating them with oxalate and studying the precipitated granules by electron microscopy^[20] or by X-ray analysis of samples marked with ^{45}Ca .^[21] Nowadays, various nanoscopic techniques are capable, in principle, not only of registering the distribution of calcium concentration within the cell, but also, when using STED microscopy, even the dynamics of calcium ions distribution inside the

cells can be revealed. For example, the use of conventional calcium dyes enabled to acquire the images of synaptic calcium microdomains of cochlear inner hair cells.^[18]

A wide range of fluorescent calcium sensors is available nowadays, but only some of them are applicable in far-field fluorescent microscopy. Therefore, we decided to design and to synthesize some new calcium sensors, which meet the following requirements:

- 1) possess excitation and emission maxima in the region above 450 nm;
- 2) have high “brightness” of a dye (brightness is the product of the fluorescence quantum yield and an extinction coefficient);
- 3) can be masked (caged) or made switchable (due to the presence of a free carboxyl group on the phenyl ring in the *ortho*-position relative to the xanthane fragment);
- 4) have high photostability;
- 5) possess high selectivity to calcium ions (selectivity is the ratio of dissociation constants of the complexes with two different cations; see equations for K_D below);
- 6) are able to penetrate through cell membrane.

The equation for the stability and dissociation constants (K_S and K_D) of a metal complex (IM) formed by the metal ion (M) and an indicator (I) is given in Figure 5. In many cases the highest possible sensitivity is required.

Figure 5. The dissociation reaction and equation for the dissociation constant K_D and stability constant K_S of the complex IM, in which I stands for indicator molecule, M for metal ion.

However, sometimes only a moderate sensitivity to calcium is required. For example, a low affinity^[22] to calcium with $K_D > 90 \mu\text{M}$ is necessary in some microscopic applications. Moreover, the ratiometric properties (see section 2.1) of calcium indicators are required in most applications. Ratiometric probes provide a shift of the extinction and emission maxima of the fluorescent sensor upon formation of a complex with an analyte. This effect may also be very helpful in optical nanoscopy, e. g. in the single-molecule switching microscopy (in spite of its low temporal resolution).^[23] In this case, the superresolution techniques may provide “calcium mapping” – the spatial distribution of calcium concentration inside a cell.

2. Fluorescent indicators for calcium cations

A typical calcium indicator consists of a fluorophore and an ionophore residue. The fluorophore moiety is responsible for the modulation of the fluorescence signal upon coordination with a calcium cation. The ionophore part must be selective enough to bind calcium ions from the environment. All fluorescence sensors may be classified according to the photophysical properties of their fluorescent parts or according to the structure of their calcium binding sites. The second classification will be pursued here with a short description of the photophysical properties of the corresponding sensors. Before that, the main photophysical principles of ion sensing by fluorescent indicators are described.

2.1. Main photophysical principles of ion sensing by fluorescent indicators and determination of calcium concentrations from the spectroscopic data

Two photophysical principles are applicable for calcium sensing: photoinduced electron transfer (PET) and photoinduced charge transfer (PCT). In the first case (PET), a donor group as part of the complexant is connected with the conjugated aromatic system of a fluorescent dye through a bridge. The donor group quenches the fluorescence of a dye due to the electron transfer from its HOMO (highest occupied molecular orbital) to the „half-filled” HOMO of the excited fluorophore (see Scheme 3), which has a lower energy. In the absence of calcium, the HOMO is mostly localized on the lone pair of a heteroatom. The sensor molecule becomes highly fluorescent upon calcium coordination, because the calcium ion acting as a Lewis acid binds by way of the lone electron pairs of the donor group. Therefore, the energy of the HOMO of the donor group in the complex decreases and the electron-transfer becomes impossible.

Scheme 3. Functional principles of PET-based calcium sensing.^[10]

In the case of PET sensors, the intensity increase of the fluorescence signal can be high enough to evaluate the calcium ion concentration. For this, it is necessary to know the fluorescence intensity of the indicator solution in the absence of calcium (I_{free}^{fl}), the fluorescence intensity of the same solution “saturated” with calcium (I_{sat}^{fl}), the value of the dissociation constant for the given calcium indicator K_D , and the fluorescence intensity of the solution with unknown $[Ca^{2+}]$ (I_x^{fl}). The calcium ion concentration can then be calculated according to equation (3).

$$[Ca^{2+}] = K_D \left(\frac{I_x^{fl} - I_{free}^{fl}}{I_{sat}^{fl} - I_x^{fl}} \right) \quad (3)$$

However, in order to evaluate the absolute value of a local calcium concentration, all values I_{free}^{fl} , I_{sat}^{fl} and I_x^{fl} have to be determined at the same total concentration of a dye, optical path length and instrumental sensitivity. For measurements inside cells, the latter conditions can not always be guaranteed.

The second principle – PCT – is applied in sensors that contain an ionophoric part integrated into a fluorescent dye, in which a calcium-sensitive electron-donor (or even electron-acceptor) group is conjugated with another electron-acceptor or (donor) group via an aromatic system. Upon excitation, a full charge transfer of the donor group to the acceptor group occurs. The excited state becomes more polar than the ground state. Therefore, interaction of a calcium cation with an acceptor group causes an decrease of energy of the excited and ground states (see Scheme 4a). These phenomena are more pronounced for the excited states than for the ground states. As a consequence, a red shift in the absorption and fluorescence spectra of a complex is observed (compared with the free ligand); and often the molar absorption coefficient of a complex increases (compared with the ϵ -value for the free ligand). Conversely, coordination of a cation with the donor moiety of the sensor causes destabilization of S_1 state to a higher degree than of the S_0 state (see Scheme 4b), which leads to a blue shift of both spectra of the complex (compared with the free ligand) and a decrease in the molar absorption coefficient (compared with the ϵ -value for the free ligand). Also, the changes of other fluorescence parameters like quantum yields and lifetimes of the excited states can be observed.

Scheme 4. Characteristic changes in the energies of the ground and excited states and the transitions ($S_0 \rightarrow S_1$) responsible for the spectral bands of the PCT-based calcium ion sensors: (a) the case, when the coordination moiety (depicted as a grey area) pulls the calcium ion towards the acceptor group; (b) the case, when the coordination moiety (depicted as a grey area) pulls the calcium ion towards the donor group.^[10]

In order to be able to calculate calcium concentrations in the case of PCT sensors, it is necessary to have compounds with large red or blue shifts of the emission or absorption bands of a complex (compared to these parameters for the free ligand). To estimate the concentration in the ratiometric mode, it is necessary to know the ratios of the fluorescence intensities (R) (not absolute intensities of the fluorescence band, as in the fluorescent mode)

for the complex and the free ligand. Moreover, it is necessary to know the ratio of the fluorescence intensities of the indicator solution at two different wavelengths – R_{\min} ; the ratio of fluorescence intensities of the same indicator solution, but “saturated” with calcium at the same wavelengths – R_{\max} ; the dissociation constant for the complex with calcium (K_D), the ratio of the fluorescence intensities of the working solution (R_x) (at the two different wavelengths), and the ratio of the fluorescence intensities of the free and bound forms of the indicator at the same (one) wavelength $I_{\text{free}}^{\text{fl}}(\lambda_2)/I_{\text{Ca-bound}}^{\text{fl}}(\lambda_2)$. With these parameters it is possible to calculate the calcium concentration according to the equations (4).

$$[Ca^{2+}] = K_D \left(\frac{R_x - R_{\min}}{R_{\max} - R_x} \right) \frac{I_{\text{free}}^{\text{fl}}(\lambda_2)}{I_{\text{Ca-bound}}^{\text{fl}}(\lambda_2)} \quad R_x = \frac{I_x^{\text{fl}}(\lambda_1)}{I_x^{\text{fl}}(\lambda_2)} \quad R_{\min} = \frac{I_{\text{free}}^{\text{fl}}(\lambda_1)}{I_{\text{free}}^{\text{fl}}(\lambda_2)} \quad R_{\max} = \frac{I_{\text{Ca-bound}}^{\text{fl}}(\lambda_1)}{I_{\text{Ca-bound}}^{\text{fl}}(\lambda_2)}$$

(4)

In spite of the more complex calculations, the ratiometric mode has important advantages: the dye content and the instrumental sensitivity may be changed from one experiment to another.

2.2. Diverse coordination moieties in fluorescent Ca^{2+} indicators

The stable form of calcium in aqueous solutions is a dication with a linear charge density of $2.02 \text{ q}\text{\AA}^{-1}$ and an ionic radius of 1.98 \AA . The most stable coordination numbers are 6–9.^[10] The following four ligands (Figure 6) provide the most stable Ca^{2+} complexes:

- 1) chelators (amino acids or amino ethers with carboxy groups);
- 2) podands (oligoethers or amino oligoethers with open chains);
- 3) coronands (usually crown ethers or amino crown ethers with 5 or 6 heteroatoms);
- 4) calixarenes (cup-shaped ligands with structures that fix the spatial positions of oxygen atoms).

Figure 6. Typical “recognizing” fragments used in fluorescent calcium sensors. If $R^1 = CH_2CH_2$, then the chelator is EDTA – the known analytically useful complexant. If R^1 contains an aromatic system, then the chelator gets some sensoric properties. R^2 is usually an aromatic or heteroaromatic substituent. R^3 is an aromatic substituent (naphthyl, anthracenyl). R^4 is a bulky group, e. g. *tert*-butyl, neopentyl which is required for the orientation of the coordinating oxygen atoms that provides calcium complexation.

2.3. Early steps in the creation of highly sensitive fluorescent calcium indicators for biological purposes

Progress in analytical chemistry stimulated the development of fluorescent calcium indicators. Complexometry represents an important analytical tool, because it allows the determination of the calcium concentration of these dications by titration. The precise determination of the end point of titration provides accurate values of the dication concentration, if an indicator with a sharp visible transition exists. For example, Calcein (**1**) provides such kind of a sharp transition from a non-fluorescent brown form to a fluorescent yellow-green form at $pH = 12$ (Figure 7).^[24] Therefore, this indicator was superior to other non-fluorescent indicators.

Figure 7. The analytical indicator Calcein for calcium dications.^[24]

Compound **1** was synthesized from fluorescein, formaldehyde and imino diacetic acid employing a Mannich reaction.^[24] In spite of the fact that the coordination number of compound **1** is 5 (which is less than the optimal value 6), the threshold level for calcium was found to be low, and therefore, this compound was successfully used in complexometry.

Four years later, the indicator **2b** was synthesized in a similar fashion (Figure 8). For this the fluorescent 4-methylumbelliferone **2a** was used as a core structure. Due to its brilliant blue fluorescence, this compound was called Calcein Blue.^[25] In the absence of calcium, aqueous solutions of this substance are intensively fluorescent only at $\text{pH} \leq 11$, but even at $\text{pH} = 12$, the solutions become fluorescent again, if a calcium salt is added. Unfortunately, in the original publication the synthesis was not reported, but some spectral data were given: the maxima of absorption (λ^{max} (acidic solution) = 330 nm, λ^{max} (basic solution) = 370 nm) and fluorescence ($\lambda_{\text{fl}}^{\text{max}} = 445$ nm).

Figure 8. Coumarin-based analytical indicators for calcium.^[25,26,28]

The properties of the coumarin derivatives **2c**, **2d** were reported by Huitink^[26] in greater details than the of Calcein Blue. The working principles of indicators **2c** and **2d** are the same as for compound **2b**. However, the working pH value for compounds **2c-d**, was found to be 13. Excitation and emission maxima of the novel indicators **2c-d** are red-shifted in

comparison with these of Calcein Blue, due to the electron-withdrawing substituents on the coumarin core [**2c**: λ^{\max} (acidic solution) = 360 nm, λ^{\max} (basic solution) = 409 nm, $\lambda_{fl}^{\max} = 447$ nm (the same for acidic and basic medium); **2d**: λ^{\max} (acidic soln.) = 348 nm, λ^{\max} (basic soln.) = 392 nm, $\lambda_{fl}^{\max} = 475$ nm (the same for acidic and basic medium)]. Along with precise synthetic procedures, this report^[26] describes also the pH dependence of the fluorescent signal, which has a maximum at pH = 8–9. This maximum is related to the deprotonation of the ammonium residue. In modern terms, the deprotonation of the ammonium moiety quenches the fluorescence due to a PET effect. At higher pH values, the neutral amino group with its lone pair can transfer an electron to a fluorophore. At lower pH values (< 8–9), the decrease in the fluorescence intensity could be explained by the contribution of a non-radiative process in the energy dissipation (e. g. post-excitational dissociation of phenol group in 7-hydroxycoumarins.^[27] The fluorescence quantum yields of compounds **2c** and **2d** were 4 and 2, respectively, times higher than that of Calcein Blue. Both compounds **2c,d** were more stable in basic solutions than Calcein Blue.

Besides all values dissociation constants and other physical data for Calcein Blue in another report by Huitink and Diehl,^[28] the new indicator **2f** was also described. It is based on the structure of umbelliferone (**2e**) and also turned out to be sensitive to calcium. Its spectroscopic properties are similar to those of Calcein Blue [λ^{\max} (acidic soln.) = 325 nm, λ^{\max} (basic soln.) = 367 nm, $\lambda_{fl}^{\max} = 455$ nm (the same for acidic and basic medium)]. Unfortunately, compound **2f** decomposes in basic solutions even faster than Calcein Blue.

With Calcein analogues, only high concentrations of calcium in aqueous solutions may be determined (in the range of ten millimolar and higher). Moreover, they require high pH values (12–13) which are far from physiological conditions in living cells. A breakthrough in the design of biologically relevant calcium sensors was realized after the report of Michaylova et al. appeared.^[29] In this work, the well-known metal-sensitive indicator **Arsenazo III**^[30] was applied for the determination of micromolar Ca^{2+} concentrations by measuring the absorption at 600 nm. The indicator **Arsenazo III** displayed an increase in the absorption maxima at 600 and 650 nm upon calcium complexation, within a linear interval of 0.030–1.50 mg / L of Ca^{2+} .

Figure 9. Spectrophotometrical metalloindicator.^[30]

It was demonstrated that **Arsenazo III** is very sensitive to low concentrations of Ca^{2+} at physiological pH values (7.0–7.4). These results as well as an other advantage of **Arsenazo III** like its low molecular mass (compared to the calcium-sensitive protein aequorine), were used by Brown *et al.* in the study of the calcium activity in squid giant axons.^[31] They used the organic calcium sensor in living cells for the first time. Brown et al. studied small influxes of calcium, originating from changing the potential of the cell membrane.

2.4. BAPTA and its derivatives

In his pioneering work, Tsien realized the first rational design and synthesis of calcium indicators for biological applications.^[32]

3a: BAPTA: $\text{R}^1 = \text{R}^2 = \text{H}$;

3b: TF-BAPTA: $\text{R}^1 = \text{H}$, $\text{R}^2 = \text{F}$.

Figure 10. BAPTA and its fluorinated analogue.^[32,39a-b]

All of them are based on the simple BAPTA (1,2-Bis(*o*-AminoPhenoxy)ethane-*N,N,N',N'*-Tetraacetic Acid) core. Compound **3a**, the simplest indicator in this family, possesses two maxima in the absorption spectrum (254 and 287 nm) and one maximum in the fluorescence spectrum (at 363 nm). Calcium complexation shifts both absorption maxima to the blue region (new positions: 203 and 274 nm) and decreases the intensity of the fluorescence maximum by a factor of 2.8. The parent compound **3a** itself is useless for any

application in biological studies, because it absorbs in the UV region. The UV light damages the cellular components containing the UV-sensitive amino and nucleic acids. The core of the BAPTA structure, however, may be modified. Tsien introduced a methyl group into the “right-hand” ring, and that increased the affinity of the derivate for calcium and its stability towards oxidation. Then the ether moiety was replaced with a pyridine ring, and that caused the required bathochromic shift of the absorption and emission bands from the 254 to 350 nm and from 363 to 520 nm, respectively. The third modification was to introduce a methoxy group into the *m*-position relative to the amino diacetoxymethyl fragment, and that improved the fluorescence quantum yield from 1.2 to 2.9%. The resulting compound was called **Quin-2** (see Figure 11). It possesses high calcium selectivity in the presence of Mg^{2+} and forms a 1:1 complex with Ca^{2+} (in comparison to the 2:1 ratio of **Arsenazo III** – Ca^{2+}).^[33] This feature made **Quin-2** quite popular, because it simplified the measurements.

Figure 11. Calcium indicator **Quin-2**.

A further important step was made one year later, when Tsien invented a delivery method for the sensors into cells, without damaging the cell membrane.^[34] He transformed the initial compound, which could not pass the membrane, into the corresponding highly acetoxymethyl ester (Figure 10, $\text{R}^1 = \text{CH}_2\text{OAc}$), which penetrates the cell membrane easily. In the cytoplasm, enzymes (esterases) convert this ester into the initial water-soluble acid form.

After numerous practical tests, it was found that the photophysical properties of **Quin-2** are not fully satisfactory for living cells. Thus, a new series of BAPTA derivatives was created.^[35] The most promising among them were the so-called **Indo-1** and **Fura-2**, (Figure 12 and Table 1).

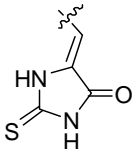

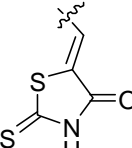

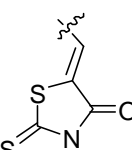

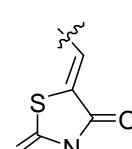

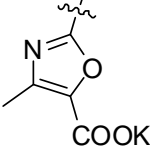

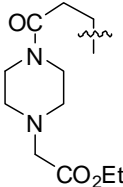

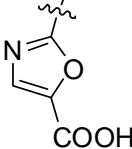

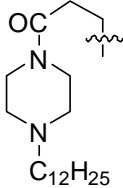

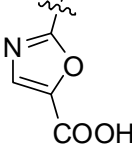

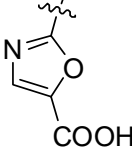

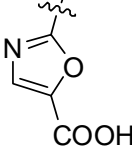

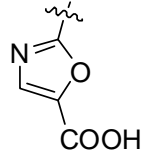

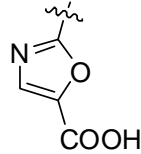

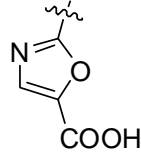

Figure 12. Indo-1 and various analogues.^[35,39b,40-42]

[a] Absorption and emission maxima for the free indicators and their complexes (No.: $\lambda_{abs}^{max} / \lambda_{fl}^{max} - \lambda_{abs}^{max}(complex) / \lambda_{fl}^{max}(complex)$, all values of wavelengths in nm); **5a**: 362 / 512 – 335 / 505;^[35] **5h**: 363 / – 340 / ;^[38a] **5i**: 364 / 508 – 335 / 495;^[38b] **5j**: 364 / 502 – 335 / 490;^[38b] **5k**: 338 / – 367 / ;^[39a,b] **5l**: 371 / 510 – 339 / 510;^[40] **5m**: 367 / 511 – 339 / 511;^[40] **5n**: 366 / 511 – 337 / 511;^[40] **5o**: 367 / 510 – 337 / 510.^[40]

The drawback of the initial BAPTA derivatives was the necessity to work at 339 nm as an excitation wavelength. But below ≈ 360 nm, the glass optics is not transparent enough, because it strongly absorbs UV light. Moreover, the autofluorescence of cells produces a high background signal, which leads to large errors in the determinations of Ca^{2+} concentrations. If the sensor brightness is high enough (which is not the case for **Quin-2** with $\epsilon \approx 5000$ and $\Phi_f \approx 3-14\%$), this problem may be circumvented. The new indicators **4a** and **5a** mentioned above have $\lambda_{abs}^{max} = 349$ or 362 nm, so that a red shift of 10–20 nm could be achieved, and the substances became more suitable for the available excitation sources in optical microscopy. Along this, the emission maxima were blue-shifted to 485 and 512 nm in **Indo-1** and **Fura-2**, respectively, and the fluorescence quantum yields were found to be 0.38 and 0.23, respectively. However, the calcium complexation provided smaller changes for the latter two sensors than for **Quin-2** (the lower the “fluorescence jump”, the lower the sensitivity of a sensor). This obstacle could be overcome by introducing the double ratiometric method of calcium determination.^[35] Another feature of compounds **4a** and **5a** is their higher Ca^{2+} affinity ($K_D = 250$ and 224 nM, respectively), than for **Quin-2**, that allows to determine the Ca^{2+} concentration at lower levels in the medium.

The high demand for compounds with properties similar to those of the Ca^{2+} sensors **4a** and **5a** stimulated further research on novel calcium indicators for elaborate applications. **Fura-2** was one of the most popular lead structures. For instance, the change of the oxazol-5-carboxylic acid part (compound **5a**) to imidazolidine derivatives (Table 1, compounds **5b-d**) or thiazolidines (Table 1, compounds **5e-g**), and the variation of the heteroatom in the benzofuran ring enabled one to create indicators with red-shifted absorption bands^[36] (and thus to improve the set-up for the flow cytometry). As a result of these improvements, high-power UV lasers could be removed from optical set-ups. Cloned cells could now be analyzed, due to the absence of emitted light originating from the cloning reagent upon excitation with UV light.

One particular study strongly suggested, that the parameters of $[\text{Ca}^{2+}]$ transients actually reached with **Fura-2** turned out to be lower than the predicted ones.^[37] Eventually, a new derivative of **Fura-2** (known also as **C₁₈-Fura-2**, **5h**) was synthesized.^[38a] The presence of a long alkyl chain resulted in the localization of this substance in the lipid bilayer of a cell membrane near the sites of calcium influx. However, compound **5h** had some drawbacks. Its brightness was only a quarter of that of **Fura-2**, and the fluorescent signal was hard to distinguish from the background signal in the cell. Another drawback was the lower K_D -value (ca. 150 nM) and, as a consequence, an earlier “saturation” of this sensor. Nevertheless, the initial rise in $[\text{Ca}^{2+}]$ transients displayed by the membrane-associated **5h** was found to be four to six times faster than that obtained with the bulk cytosolic fluorescent calcium indicators like **Fura-2**. One of the drawbacks of **5h** was partially alleviated by creating the new sensor **FFP18**.^[38b] Instead of a thiocarbonyl amino group, this compound had a propionic acid residue and a piperazine ring which serve as a bridge between the long alkyl chain and the aminophenyl group. Compound **FFP18** displayed a K_D value that is twice as high as that of **5h** (330 nM vs. 150 nM). This feature, as well as the long dodecyl residue, which can anchor the dye in the cell membrane, may provide more reasonable data on the parameters of calcium transients.

Another drawback of **Fura-2** was found by molecular biologists. This substance rapidly leaked out of the cell or was transported to the vacuoles due to a specific mechanism of active transport of its anionic form. However, in the presence of positively charged groups, the behavior of this compound is different. Therefore, a new zwitterionic fragment based on a piperazine residue was incorporated into the structure of **Fura-2** (see Table 1).^[38b] To avoid changes in pH sensitivity, a propionic acid fragment was incorporated between the piperazine moiety and the aromatic rings in compounds **5i**, **5j**. The K_D value of the sensor **5i** was 50%

larger than that of **Fura-2**, and this indicator was hold back in cells quite well. The latter fact was confirmed by the low drift of the apparent baseline of internal $[Ca^{2+}]$: in 1 hour this line drifted 7 times more slowly than in the case of **Fura-2**.

With their new Ca^{2+} sensor **TF-BAPTA** (see Figure 10), London et al.^[39a,b] introduced compounds with a new range of available K_D values. Compound **TF-BAPTA** showed a K_D value of about 65 μM , and allowed dual measurements of metal ion concentrations. This progress was achieved by the introduction of two fluorine atoms into each of the BAPTA rings. First of all, optical mode of measurements is the same as in the case of the common BAPTA sensor, when the concentration of calcium is determined by measuring the optical density. The second mode is based on the dependence of the ^{19}F chemical shift of $R^2 = F$ (compound **3b**, Figure 10) on the Ca^{2+} concentration. The variation of this chemical shift may be as large as 9.7 ppm. Unfortunately, as in the case of BAPTA, the sensor **3b** cannot be used for the determination of calcium concentration by measuring the fluorescence signal. There are cases, for which indicators with low calcium affinities are required in biological studies. For instance, for studying cells or organelle systems with micromolar Ca^{2+} contents, or for the evaluation of very high variations in calcium concentration (e. g. by ischemia), a low affinity is required. For these applications the **Fura-F** sensor was designed and synthesized. It displays a K_D value of 20–30 μM with lower sensitivity to pH (at physiological values of 5–8) than **Fura-2**, and low sensitivity to Mg^{2+} (even when $[Mg^{2+}] = 75$ mM). The presence of two fluorine atoms in the “right-hand” phenyl ring (R^4 in compound **5k**, Table 1) makes it possible to use the chemical shift of one of them for an additional evaluation of the K_D value. The maximal span of the ^{19}F chemical shift values was found to be 9.2 ppm.

The monohalogenated **Fura-2** derivatives **5k-o** were prepared in the search for indicators which possess K_D values intermediate between those of **Fura-2** and **Fura F**.^[40] This indicator series shows no substantial deviation in the excitation and emission spectra compared to **Fura-2**. However, an influence of the position and nature of the halogen atom in the “right-hand” phenyl ring (Table 1) on the K_D value was detected. The chlorine atom in compound **5n** and the fluorine atom in compound **5m** in the *para*-position to the amino group have the same influence on the K_D value (400 nM for both compounds **5n** and **5m**). This value increases, when the fluorine atom is in the *ortho*-position to the ether oxygen as in compound **5l**, and drastically increases, when the fluorine atom occupies the *para*-position to the ether oxygen as in compound **5o**.

Another calcium sensor (**Indo-1**) reported by Tsien et al. in 1985 was not widely used for elaborate optimization. However, its analogues with low calcium affinity were developed (e.

g. the monofluorinated derivative **4b**^[40] and the difluoroanalogue **4c**^[39b] in Figure 12). Compound **4b** possesses a K_D value which is twice as high as that of **Indo-1**. A new modification of **Indo-1** was introduced by Sanchez-Martin et al.^[41] It offered two advantages simultaneously: the delivery into and the preservation of the indicator in the cell. These advantages were achieved by the synthesis of the adduct of **Indo-1** on aminomethylated polystyrene microspheres. The final product **4d** (Figure 12) featured a 10 nm blue shift of the emission maximum upon calcium binding, and its K_D value is similar to that of **Indo-1** (226 nM). “Leakage” of the sensor could not be detected, and no cell degradation was observed. The sensor **4d** was not toxic to the cells and located in the cytosol without compartmentalization.

The other authors prepared an adduct of **Indo-1** with *O*-(4-aminomethylbenzyl)guanine,^[42] in order to use it as a specific marker for SNAP-tagged proteins,^[43] which can react with small cell-permeable molecules containing *O*-alkylguanine residues. On this basis, a new method for the selective detection and the study of calcium signals was elaborated. The SNAP-tagged protein was localized in the cell nucleus. Initially, compound **4e** had an absorption maximum with a red shift of 10 nm compared to **Indo-1**. After binding compound **4e** to the SNAP tag, the red shift decreased to 5 nm. Although the fluorescence maximum of the free form of compound **4e** was red-shifted (about 39 nm) in comparison with that of the free form of compound **4a**, the fluorescence maximum of Ca-complexed **4e** was the same as for the Ca-complexed **4a**. The fluorescence maximum of the conjugate **4e** with the SNAP tag did not change substantially both in the Ca-free form and the Ca-bound form in comparison with the corresponding values for compound **4a**. The dissociation constant K_D of the calcium complex with **4e** diminished by 30% in comparison with that of the calcium complex **4a**. Fluorescence quantum yields Φ_f were two times lower for both forms of **4e** (with and without calcium) compared to the corresponding values for compound **4a**. Upon binding compound **4e** with the SNAP tag, K_D and Φ_f values were recovered (completely or partially) up to those of compound **4a**. The low fluorescence quantum yield of the free dye **4e**, together with the considerable increase in the fluorescence intensity occurring upon binding to the SNAP tag, increases the contrast of measurements. Besides that, an irreversible coupling of **Indo-1** with the SNAP tag prevented the leakage and translocation of the indicator.

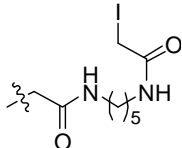

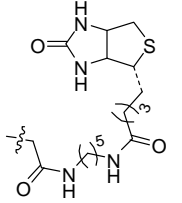

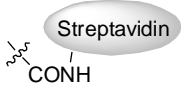

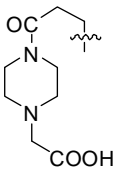

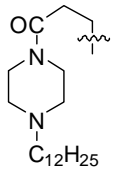

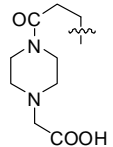

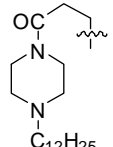

One of the main problems in the application of **Fura-2** and **Indo-1** in biological studies is the necessity to excite their fluorescence with UV light. In order to shift the main absorption band to the red, conventional dyes such as fluoresceins and rhodamines were combined with

the BAPTA chelator.^[44] The later was attached to the phenyl substituent of these xanthene dyes.

[a] The values of absorption and emission maxima for free indicators and their complexes (Nr.: $\lambda_{abs}^{max} / \lambda_{fl}^{max} - \lambda_{abs}^{max}(complex) / \lambda_{fl}^{max}(complex)$, all values of wavelengths in nm); **6a**: 556 / 578 – 556 / 578;^[44] **6b**: 553 / 576 – 553 / 576;^[44] **6c**: 499 / 521 – 499 / 521;^[44] **6d**: 493 / 518 – 493 / 518;^[44] **6e**: 506 / 526 – 506 / 526;^[44] **6f**: 494 / 516 – 494 / 516;^[47] **6g**: 491 / 516 – 494 / 516;^[47] **6h**: 491 / 516 – 494 / 516;^[47] **6i**: 491 / 516 – 494 / 516;^[47] **6j**: 495 / 517 – 495 / 517;^[48] **6l**: 496 / 520 – 496 / 520;^[48] **6m**: 495 / 518 – 495 / 518;^[48] **6n**: 494 / 517 – 494 / 517;^[48] **6o**: 495 / 518 – 495 / 518;^[48] **6p**: 495 / 518 – 495 / 518;^[48] **6s**: / 526 – / 526;^[49] **6v**: / 515 – / 515;^[49] **6w**: / 540 – / 540;^[50] **6x**: 364 / 517 – 335 / 517;^[51] **6y**: 580 / 602 – 580 / 602;^[8] **6ab**: 579 / 598 – 579 / 598.^[52]

As a result, the new series of calcium sensors **6a-e** emerged, with absorption maxima in the region of 500 nm (**Fluo-1**, **Fluo-2**, **Fluo-3**) to 550 nm (**Rhod-1**, **Rhod-2**), with Stokes shifts of about 20–25 nm. These spectroscopic properties of the xanthene-based indicators could not interfere with natural fluorescence of cell components (autofluorescence) and allowed to work simultaneously with UV-photolyzable calcium chelators (see Figure 13) like **nitr-5**, **nitr-7**,^[45] and **DM-nitrophen**.^[46]

Figure 13. Photolyzable calcium chelators for a controlled release of calcium cations upon illumination with UV light. The irradiation destroys the polydentate ligand by cleaving the nitropiperonyl or the nitroveratryl groups.

The higher dissociation constants of the **Fluo**- and the **Rhod**-sensors (compared to **Fura-2**) have improved the resolution of different concentrations in the micromolar range of intracellular calcium (K_D for **Fluo-1**, **Fluo-2**, and **Fluo-3** – 0.7, 0.37, 0.40 and for **Rhod-1**, **Rhod-2** – 2.3, 1.0 μM , respectively). The high increase in fluorescence intensity upon cation coordination (40-fold for **Fluo-3**) enhanced the sensitivity to calcium in the whole interval of concentrations (0.1 K_D to 10 K_D). In the cases of high and low calcium concentrations, sensitivity is not lost. However, this series of indicators had the same drawback as **Quin-2**, it provided only low brightness. Apart from that, the shift of the fluorescence maxima of xanthene sensors upon calcium complexation was too small, and they cannot be used for ratiometric measurements. In this case, in order to evaluate the absolute value of a local calcium concentration, some information on local dye concentration is required, as well as optical path length and instrument sensitivity. However, two promising xanthene indicators emerged. The first one – **Rhod-2** – possessed a mitochondrial localization as a valuable feature. The second one – **Fluo-3** – had a lower pH sensitivity than related compounds (e. g. **Fluo-1** and **Fluo-2**).

Fluorinated analogues of **Fluo-3** were developed by K. Gee and co-workers.^[47] The new indicator **Fluo-4** (compound **6f**, see Table 2) is a brighter fluorescent dye in vitro and in vivo compared to compound **Fluo-3** (upon excitation with an argon laser at 488 nm). As has already been mentioned, the brightness of a fluorescent dye is the product of the extinction coefficient (ϵ) and the fluorescence quantum yield (Φ_f). Since the Φ_f values and the position of the emission maxima of compounds **6e** and **6f** are similar, and the ϵ value at the “working” wavelength of 488 nm is 1.8 times higher for the indicator **6f**, compound **6f** gives brighter pictures than **6e**. It is possible to use a lower concentration of a “brighter” dye to gain the same signal intensity. Low dye concentrations reduce buffering effects and the amount of

toxic photolysis products. Brighter dyes provide the possibility to use lower illumination intensities with the same dye concentration. Lower illumination intensities are advantageous as they cause lower photobleaching of the indicator. In addition, by replacing the methyl group at the positions of R³ with acceptor groups, the series of **Fluo-4** analogues (**6g-i**) was prepared. They possess similar spectral properties, but their calcium affinities are lower than that of **Fluo-4** (**6g** – 2.3 μ M, **6h** – 6.2 μ M, **6i** – 90 μ M; for comparison, the K_D of **Fluo-4** is 0.35 μ M). K_D values of compounds **6g-i** correspond to physiological Ca²⁺ levels.

Perfect photophysical properties made the indicator **Fluo-4** to be one of the main candidates for further improvements. The first attempt – compound **6j** – was not a success.^[48] A carboxy group was introduced into the *para*-position relative to the ether oxygen atom in the structure of compound **6e**, which caused a significant decrease in calcium affinity of the resulting derivative **6j**. The second derivate of **Fluo-4** – compound **6k**^[48] – displayed higher calcium affinity (probably due to the presence of the methylene bridge between the aromatic ring and the carboxy group). Eventually, the adduct of compound **6k** with dextran – compound **6l** – was prepared. Dextran, as a voluminous fragment, increases the retention time of **6l** in living cells and improves the intracellular protein binding. However, compound **6l** has a serious disadvantage: the low Φ_f value (ca. 3% at saturation with calcium and ca. 0.2% in its absence); these values were even lower than for **Quin-2** in both forms. A series of further conjugates were synthesized from compound **6k**, which could label other cell compartments: a) fluo-4-cadaverine **6m** for labeling of proteins through the activated carboxylate groups; b) compound **6m** for the labeling of ribonucleotide after periodate cleavage; c) a thiol-reactive compound called fluo-4-iodoacetamide **6n** for cysteine residues; d) biotinylated indicator fluo-4-biotin **6o** for obtaining a very stable biotin-(strept)avidin complex. In order to confirm the utility of **6o**, the streptavidin complex **6p** of this compound was prepared. The whole series of **Fluo-4** derivatives had very similar fluorescence and absorption spectra, but their calcium affinities and fluorescence enhancements upon calcium coordination are lower than those of **Fluo-4**.

Similar problems – leakage and compartmentalization^[38b] – were again encountered by the same authors nine years later, and were solved by the same methods.^[49] Sensors **FLUO-3-LR** and **FLUO-4-LR** (see Table 2), elaborated analogues of **Fluo-3** and **Fluo-4**, respectively, were prepared. Comparing the sensor structures in Tables 1 and 2, one can notice that the modification of the sensors was carried out in exactly the same manner as in the previously described compound **Fura-2**, which was replaced by compound **PE3** (see Table 1). Derivatives with a long hydrocarbon chain (compounds **6r** and **6u**, see Table 2) were also

synthesized to monitor the near membrane calcium transients. Two interesting **Fluo** analogues were disclosed: **FLUO-KOJO** and **FLUO-LOJO** (see Table 2).^[49] Both compounds are the precursors to other optimized indicators (**6q-r**, **6t-u**), and both contain only a propionic acid residue, but do not contain a piperazine fragment as do compounds **6q-r**, **6t-u**. Nevertheless, according to the report,^[49] they show a “general leakage resistance” (50% less leakage of **FLUO-LOJO** in one hour compared to **Fluo-4**).

J. Han et al. prepared compound **6w**, the analogue of **Fluo-3** with different positions of chlorine atoms (Table 2).^[50] This new indicator **6w** had a slightly more red-shifted excitation maximum (540 nm vs. 526 nm in **Fluo-3**), and displayed a 9-fold increase in fluorescence signal upon changing the calcium concentration from 0 to 50 μM .

An enormous number of potentially useful calcium sensors have been described by Diwu and co-workers.^[51] They were built on the basis of BAPTA and various fluorophores (xanthenes, acridines, carbopyranines). Unfortunately, the functional properties of these indicators were demonstrated only in one plot with the fluorescence spectrum of one compound (**6x**), a derivative of **Fluo-2** with a carboxy group as R^2 (see Table 2). The structural similarity with **Fluo-2** explains the presence of the highly fluorescent form of **6x** upon “calcium saturation” (at 0.5 mM) with a fluorescence maximum at 517 nm and the absence of a fluorescence signal without calcium cations. The same authors also observed a more than 100-fold increase in the fluorescence signal upon calcium binding for the whole series of **Fluo-2**, **Fluo-3** and **Fluo-4** derivatives (partially with various substituents R^2 , or acetoxymethylated derivatives of the parent indicators).

Indicators which absorb green or red light, allow one to neglect autofluorescence, and offer the possibility to simultaneously use calcium indicators and photoactivable calcium chelators. For example, **X-Rhod-1** (**6y**) was created by Molecular Probes Inc.^[9] In comparison with the nearest analogue **Rhod-2**, the excitation/emission maxima of compound **6y** were red-shifted by ca. 26 nm to 580/602 nm, and the calcium affinity was increased by 30% (to 700 nM). This indicator (**X-Rhod-1**) was applicable for the simultaneous detection of Ca^{2+} transients and green-fluorescent protein (GFP) labeling with a minimal crosstalk. Fluorinated analogues of **6y** – **X-Rhod-5F** (**6z**) and **X-Rhod-FF** (**6aa**) – have similar photophysical properties as compound **X-Rhod-1**, and can be used for measurements of various calcium levels, according to their increased dissociation constants (1.6, 17 μM , respectively).^[9]

Another indicator, **6ab** (see Table 2), with similar photophysical properties and structure as **X-Rhod-1**, was prepared by Gaillard and co-workers.^[52] However, compound **6ab** had

some important changes in structure which improved its performance (in comparison with **X-Rhod-1**). An aliphatic chain with a terminal azido group was introduced. The azido alkyl residue was connected with the ethylene-1,2-dioxy bridge of the BAPTA fragment. A chlorine atom was also introduced in the *para*-position relative to the ether bridge. The position of the azidoalkyl moiety was chosen in such a way that it is “less interfering with the functional part of the indicator”.^[52] Indeed, it resulted in a sharp increase of the dissociation constant from 0.7 (for **X-Rhod-1**) to 30.3 μM . Undoubtedly, at least a part of this increase is due to the effect of the chlorine atom, but not the whole increase, as the authors considered.^[52] Besides that, the azido group provided additional possibilities to link this indicator to various objects (e. g. dextran, colloidal semiconductor nanocrystals), either by using “click chemistry” with acetylene-tagged molecules, or by Staudinger ligation, or by EDC-assisted coupling with any carboxy group (after reduction of an azido to an amino group). It should be noted, that the authors have not given a correct evaluation of the efficiency of the indicator **Calcium Ruby-Cl (6ab)**.^[52] Usually, the efficiency of an indicator correlates with the value for the fluorescence ratio. The fluorescence ratio is the ratio of fluorescence quantum yields of the indicator in the free and the complexed form. However, for their indicator **6aa** the authors^[51] only estimate the quality on the basis of the ratio of the absolute intensity of the fluorescence emission maxima of the free and the complexed form of **6ab**. Thus, the authors claimed a higher performance of **6ab**, in comparison with **Rhod-2**,^[44b] although they compared two “uncomparable” ratios ($I_{\text{Ca}^{2+}\text{-free}}^{\text{fl}} / I_{\text{Ca}^{2+}\text{-bound}}^{\text{fl}}$ for **6aa** and $\Phi_{\text{Ca}^{2+}\text{-free}} / \Phi_{\text{Ca}^{2+}\text{-bound}}$ for **Rhod-2**), since fluorescence intensity is proportional not only to the fluorescence quantum yield, but also depends on the absorbance in the indicator solutions.

Unlike the **Indo** and **Fura** series, calcium indicators based on a xanthene fluorophore also enabled to shift the absorption bands to the red. However, xanthene-based sensors also have a drawback: there is no possibility to do ratiometric measurements with them. To circumvent this problem, another class of fluorophores – coumarines – was used.^[53]

Table 3. Coumarine-based calcium indicators.^[a]

[a] Absorption and emission maxima for free indicators and their complexes in the form: No.: $\lambda_{abs}^{max} / \lambda_{fl}^{max} - \lambda_{abs}^{max}(complex) / \lambda_{fl}^{max}(complex)$, all values of wavelengths in nm; **7a**: 444 / 510 – 390 / 510;^[53] **7b**: 405 / 480 – 356 / 480;^[53] **7c**: 447 / 510 – 415 / 510;^[53] **7d**: 462 / 525 – 401 / 525;^[53] **7e**: 462 / 525 – 401 / 525;^[54] **7f**: 471 / 535 – 414 / 535;^[55] **7g**: 471 / 521 – 409 / 521;^[55] **7h**: 469 / 519 – 401 / 499;^[55] **7j**: 470 / 530 – 421 / 530;^[56] **7k**: 403 / 480 – 358 / 475;^[57]

By variation of the substituents R² (Table 3, compounds **7a-d**), H. Iatridou et al. managed to obtain the very interesting and promising compound **7d**. This new indicator has a fluorophore, which may be excited with visible light (462 nm). Moreover, it has a big “blue” shift of the absorption maximum (61 nm) upon calcium coordination (the non-shifted emission maximum is detected at 525 nm). At the time of publication, indicator **7d** possessed the highest dissociation constant (7 μ M). However, its fluorescence quantum yield was lower than that of **Quin-2**; the values for the “free” and “complexed” forms were 0.07 and 0.12, respectively.

Compound **7e**, a fluorinated analogue of BTC (**7d**), was invented by K. Takesako and co-workers.^[54] Indicator **7e** has the same photophysical properties as its analogues, and an extraordinarily low affinity to calcium (550 μ M). This property facilitates the measurements of Ca levels in the endoplasmatic reticulum.

To increase the polarity of BTC **7d** and provide the possibility for structural variations, a series of imino analogues of this compound were synthesized.^[55] Introduction of the imino group was accompanied by an improvement of calcium sensitivity (fluorescence increase for **7f** was five times stronger than that of BTC, a decrease in the dissociation constants (e. g. 27.5 μ M for **7h**), moderate bathochromic shifts of the absorption and emission maxima (up to 10 nm), shifts of the fluorescence maxima upon calcium coordination, e. g. for compound **7h** by 20 nm. The dodecyl analogues of BTIC and BIIC – C₁₂-BTIC and C₁₂-BIIC – were prepared later.^[56] The main advantage of these coumarine calcium indicators is their near membrane localization combined with a high dissociation constant (5.50 μ M for **7i**, 4.49 μ M for **7j**). Initially, the calcium sensors for measurements in inner-membrane vicinity possessed an affinity in the hundred nanomolar range. Sensitivity to calcium, in comparison with the non-dodecylated analogues (BTIC and BIIC), increased by a factor of two for **7i** and decreased by more than a factor of five for **7j**.

A monofluorinated analogue of compound **7a** was prepared by H. Komatsu and co-workers.^[57] The new indicator **7k** has a low affinity to cations (K_D (Ca²⁺) – 14 μ M, K_D (Mg²⁺)

– 26 mM), a small shift of the fluorescence maximum upon metal ion coordination (free ligand: 480 nm, Ca^{2+} / Mg^{2+} : –5 / +5 nm) and a big shift of the absorption maximum (free ligand: 403 nm, Ca^{2+} / Mg^{2+} : –45 / +21 nm). The calcium coordination causes a decrease in absorption and fluorescence intensities, the opposite effect was observed upon magnesium coordination – an increase in absorption and fluorescence intensities. The authors claimed, that the sensitivity of this compound to two analytes (Mg^{2+} and Ca^{2+}) is an advantage, and the different directions of response is a feature which helps to separate the magnesium and calcium signals. However, it should be noted, that in almost all of the above mentioned articles, the authors have presented an opinion exactly opposite to that.^[32,35,44] Usually the presence of magnesium ions influences the determination of the calcium concentration, because they also input into the background fluorescence signal. Any shift of the spectroscopic maxima (one from the other) of indicator solutions upon calcium and magnesium coordination may help to separate the magnesium signal away from the calcium signal, but only after complex calculations. Thus, the sensitivity of compound **7k** to calcium and magnesium ions makes the precise measurements of the Ca content in living cells next to impossible. The main reason is the presence of both cations in the cells. However, for *in vitro* experiments, the indicator **7k** can be suitable.

Figure 14. Indicators for calcium with a phenylbenzothiazole fluorophore.^[40]

The benzothiazolo-BAPTA derivatives **8a,b**, with a shorter conjugated chain (in comparison with **BTC**) was prepared by K. R. Gee et al.^[40] Such a cut of the conjugated chain caused a 100 nm blue shift of the excitation maximum in comparison with **BTC**. Calcium complexation provides only a 36 nm blue shift of the absorption maximum (almost two times lower than the value of **BTC**). However, the new indicators were twice as bright as **BTC**. Moreover, the required binding affinity (1.4 μM for **8b**) was achieved.

A completely different approach was pursued in the preparation of the so-called “Green” series of indicators by Molecular Probes Inc.^[9] Instead of including the fluorophore into the BAPTA chelator, these parts were separated by a phenylcarboxamide group. This change made the preparation easier, because all indicators have the same chelator. The separation of the BAPTA chelator from the fluorophore part led to a 5-fold increase in the fluorescence quantum yield (**9a**: 0.75, **9c**: 0.7, in comparison with **Fluo-3**).

Table 4. “Green” series of calcium indicators.^[a]

| No. | Nickname | K_D (Ca^{2+}) μM | R^1 | R^2 | R^3 | R^4 | R^5 | R^6 | R^7 | X | Y | Z |

| | | | | | | | | | | | | |
|-----------|----------------------------------|------|---|--|-----------------|----|---|---|--------------|---------------|---|----|
| 9g | Calcium Crimson | — | H | H | SO_3^- | | | N | N^+ | SO_2 | | |
| 9h | Calcium Green C ₁₈ | 0.23 | H | $\text{NHCO}(\text{CH}_2)_{16}\text{CH}_3$ | COO^- | Cl | — | — | H | O^- | O | CO |

Calcium Green C₁₈ is located on the outer side of the cell membrane and may be excited with light of 500 nm. For the first time it was prepared on the basis of the structure **9a**.^[58] The main disadvantage of this sensor is its very low dissociation constant (0.23 μM). This value causes determination of the near-membrane calcium spikes to be inaccurate.

The typical PET sensors **10a-c** (see Section 2.1 for a description of this effect) were designed and synthesized by Prasanna de Silva and co-workers.^[59] In this series of compounds, the anthracene and pyrazoline fluorophores were separated from the conjugated system of a chelator by an sp³-carbon atom (Figure 15).

Figure 15. Highly sensitive BAPTA indicators with different fluorophores.^[59,60]

Such structural features resulted in a dramatic increase in the fluorescence quantum yield upon calcium coordination; this effect was especially pronounced for compound **10b** ($\Phi_{\text{Ca}^{2+}}$).

$\Phi_{\text{Ca}^{2+}\text{-free}}^{\text{bound}} = 92$; and only 16 for **10a**). Most of the properties of these indicators were brilliant: high extinction coefficients ($\epsilon \sim 10^4$), high selectivity for calcium in the presence of magnesium, and independence of the fluorescence intensity from pH ($7.0 \leq \text{pH} \leq 7.4$). However, apart from these advantages, these sensors (**10a,b**) have serious drawbacks, preventing their use in biological measurements: 1) short wavelengths of the excitation and emission maxima (**10a**: 368 / 440 nm, **10b**: 388 / 489 nm); 2) low Φ_f -values (≤ 0.10 ; also for calcium complexes). Interestingly, the indicator **10c** (Figure 15) lacked the advantages, which **QCa1** had. The main reason is the presence of a second deexcitation channel due to the ether oxygen atom. Thus, the fluorescence enhancement in this case ($\Phi_{\text{Ca}^{2+}\text{-bound}}^{\text{2+}} / \Phi_{\text{Ca}^{2+}\text{-free}}^{\text{2+}}$) is only 80%.^[60]

Figure 16. Examples of BAPTA-sensors with two fluorophore fragments.^[9,61]

With the two fluorophore fragments in the new BAPTA-based indicators presented in Figure 16, a unique fluorescence enhancement upon calcium complexation of up to 180-fold was observed.^[9,61] Unfortunately, the enormous sensitivity to calcium ions was achieved at the expense of a decrease in the fluorescence quantum yields (compounds **11a-c**; both in the Ca-free and in the Ca-bound forms, compared with the monofluorophore indicators **10a**, **10b**, **6b**). A second characteristic feature of the new indicators was associated with the lower affinities to calcium ($K_D(\mathbf{11b})/K_D(\mathbf{10b}) - 20$ times, $K_D(\mathbf{11c})/K_D(\mathbf{6b}) - 5.5$, $K_D(\mathbf{11d})/K_D(\mathbf{9a}) - 2.9$, $K_D(\mathbf{11e})/K_D(\mathbf{9c}) - 3.4$). Most probably, these lower affinities are due to the steric hindrance caused by the two fluorophores, which destabilized the Ca-bound form relative to the Ca-free form. However, the sensor **11a** with an anthracenyl-methyl fragment, which has

more degrees of rotational freedom, showed the opposite change in its dissociation constant (1.6-fold decrease compared to **10a**).

Figure 17. Calcium sensor with a squaraine fluorophore.^[62]

To develop an analytical tool for calcium concentration measurements using the near-IR region, the squaraine chromophore was chosen.^[62] Its very high extinction coefficient ($>3 \times 10^5 \text{ cm}^{-1} \text{ M}^{-1}$), absorption in the red region (635–690 nm) and its near-IR emission (650–700 nm) are in accordance with the requirements. Combination of this fluorophore with the BAPTA chelator gave the new calcium sensor **12**. This novel indicator had its absorption maximum in the red, and the fluorescence maximum in the near-IR region (698/733 nm). Complexation with calcium is accompanied by a 6-fold decrease of the extinction coefficient and a 5-fold decrease in the emission intensity. The sensitivity to calcium of compound **12** is in a micromolar region.

Figure 18. Calcium sensor with a cyanine chromophore.^[63]

As a continuation of the previous work, an indicator based on a trimethylindolenine derivative of a cyanine dye was prepared.^[63] Seven methine carbon atoms between the heterocyclic fragments in **13** provided the required IR excitation and emission maxima (766/782 nm). Therefore, no background fluorescence was observed by using this sensor in living cells. However, with its excellent extinction coefficient ($2 \times 10^5 \text{ cm}^{-1} \text{ M}^{-1}$), compound **13** was only a satisfactory sensor. Namely, the dissociation constant was found to be 240 nM, and the increase in the fluorescence quantum yield upon calcium coordination was found to be 2.4-fold. Although the above-mentioned parameters were in the same range as for **Fura-2** and **Indo-1**, compound **13** was deprived of the ratiometric properties and possessed a narrow dynamic range. Low changes in the quantum yield (e. g. from 0.05 to 0.12) for the PET sensor **13** could be explained in the same manner as for the above mentioned compound **10c**.

- 14a:** $R^1 = R^2 = X = H$, $Y = \text{Me}$;
14b: $R^1 = \text{CH}_2\text{CH}_2\text{COOH}$, $R^2 = X = H$, $Y = \text{Me}$;
14c: FluoRhod-2: $R^1 = \text{CH}_2\text{CH}_2\text{COOH}$, $R^2 = Y = \text{Me}$, $X = H$;
14d: Fluo-Rhod-F: $R^1 = \text{CH}_2\text{CH}_2\text{COOH}$, $R^2 = H$, $X = Y = F$.

Figure 19. The FluoRhod series of indicators.^[64]

The mode of incorporating of the BAPTA chelator into excellent and bright fluorophores, such as fluoresceins and rhodamines, was firstly described by R. Tsien in 1989,^[44] but it was later rejected by him as unpromising. However, this approach was implemented several years later by G. Smith in the double-ratiometric sensor **FluoRhod-2** (see Figure 19).^[64] As it concerns fluorescence quantum yields and the spectral shift upon calcium coordination, the new indicator was like **Fura-2**. However, as it was predicted by R. Tsien, compound **14a** had a higher dissociation constant and, due to the rhodole structure as a fluorophore, the absolute value of the fluorescence quantum yield was lower than for the parent xanthenes (fluorescein and the rhodamines). Undesirable features, like a decrease in the calcium affinity and a low

pK_a-value of the initial indicator **14a** (which produces a dependence of the fluorescence ratios of an indicator at pH-values even in the physiological range) were corrected later by variation of substituents. Thus, introduction of a carboxyethyl fragment into the R¹ position (see Figure 19, intermediate structure **14b**) provided the required pK_a value of 6.7 and therefore, independence of the fluorescence from pH in the physiological range of 7.0-7.4. Introduction of an additional methyl group into one of four carboxymethyl residues enabled one to decrease the *K*_D value from 10 μM to 1 μM (see Figure 19, final structure **14c**). Moreover, compound **14c**, in comparison with the most popular ratiometric indicators (**Fura-2**, **Indo-1**), had suitable shifts of both spectral maxima upon calcium complexation (absorption: 57 nm; emission: 30 nm). An analogue of **14c** was prepared, which got the name **Fluo-Rhod-F** and could potentially be applied in dual measurement modes: both in ¹⁹F NMR spectroscopy and fluorescence. The presence of two fluorine atoms in compound **14d** resulted in a lower calcium affinity (*K*_D > 10 μM), compared to the related compound **14c**.^[39b]

2.5. APTRA and its derivatives

Replacing one imino diacetic fragment in the EDTA chelator (see Figure 6) with an oxyacetic fragment, together with an ethylene bridge containing an aromatic ring, gave the APTRA chelator (**15a**). It has a reduced number of coordinating atoms (5 vs. 6) and a reduced number of nitrogen coordination sites (in favor of oxygen atoms). Moreover, the APTRA chelator contains significantly less coordinating heteroatoms than the BAPTA chelator described in section 2.4 (5 vs. 8).

Figure 20. A variety of APTRA-based calcium indicators.^[65-68]

Obviously, a change in quality, quantity and spatial localization of chelator ligands influences the coordination properties of the indicator. Thus, for example, compound **15b**^[65] had a dissociation constant of the calcium complex in the range of 50 μ M and the Φ_f -value for the Ca-free ligand 0.74. In principal, such values could be perfect for indicators, but only in terms of the absolute values. More important are the changes in these values upon calcium coordination; and these were not so promising for **Thio-H (15b)**: a) the decrease in fluorescence quantum yield was only 1.5 fold (not perfect for an application of this indicator in fluorescence mode); b) compound **15b** was 100 times less selective for Mg²⁺ than **Fura-2** (having the same K_D for Mg²⁺ as **Fura-2**, compound **15b** has a K_D for Ca²⁺ which is in 100 times higher than that of **Fura-2**); c) an undesirable sensitivity of **Thio-H** to temperature and pH in the physiological range (7.0–7.4) was observed; d) like **Fura-2 (5a)**, it has to be excited with blue or UV light ($\lambda_{abs}^{max} = 351$ nm); e) upon calcium coordination, this indicator displays rather small shifts in its absorption (ca. 19 nm) and emission spectra (no shift), which prohibits ratiometric measurements. All the factors mentioned above cause compound **15b** not to be very promising for applications in biology.

In order to develop more suitable indicators, further efforts were aimed at the replacement of the substituents in the *para*-positions relative to the amino group. The second candidate

15c had better properties as a biocalcium indicator: a) absorption and emission maxima were in the visible region (470/538 nm); b) increase in the fluorescence quantum yield upon calcium coordination was in the same range as for **Quin-2** ($\Phi_{\text{Ca}^{2+}\text{-bound}}^{2+}$ (0.048) / $\Phi_{\text{Ca}^{2+}\text{-free}}^{2+}$ (0.012) = 4), although the absolute values were not very high; c) the dissociation constant ($K_D = 10 \mu\text{M}$) was suitable for detection of elevated intracellular levels of calcium.^[66]

Two PET calcium indicators **15d-e** were obtained by a favorable combination of an APTRA chelator with BODIPY[®] derivatives.^[67] Both indicators had photophysical properties very similar to those of **Fluo-3**, i.e. fluorescence quantum yields and increase in fluorescence intensities were actually the same (**15d**: $\Phi_{\text{Ca}^{2+}\text{-bound}}^{2+} = 0.14 / \Phi_{\text{Ca}^{2+}\text{-free}}^{2+} = 0.004$, $I_{\text{Ca}^{2+}\text{-free}}^{\text{fl}} / I_{\text{Ca}^{2+}\text{-bound}}^{\text{fl}} = 40$; **15e**: $\Phi_{\text{Ca}^{2+}\text{-bound}}^{2+} = 0.13 / \Phi_{\text{Ca}^{2+}\text{-free}}^{2+} = 0.003$, $I_{\text{Ca}^{2+}\text{-free}}^{\text{fl}} / I_{\text{Ca}^{2+}\text{-bound}}^{\text{fl}} = 30$). The compound **15d** even had virtually the same excitation and emission maxima (505/525 nm) as **Fluo-3**. The second indicator **15e** with two *p*-methoxyphenyl substituents, showed wavelength maxima shifted to the red (570/625 nm). A red shift in the spectra favors practical applications. The main difference to “Tsien’s sensor” (**Fluo-3**) was the new “working interval” (which has to be from 0.1 K_D to 10 K_D): the dissociation constants of **15d,e** were $\sim 100 \mu\text{M}$, i.e. in 250 times greater than that of **Fluo-3**.

Other derivatives of **15b** were prepared with an additional thiophene ring and with functional groups in conjugation with the amino group (see Figure 20).^[68] Extension of the conjugation path by the additional thiophene ring gave compound **15f** with a red-shifted excitation maximum (35 nm in comparison with **Thio-H**). However, the same extension of the conjugated system could be the main reason for the decrease in the absolute value of the fluorescence quantum yield (to 0.25). The latter value was successfully compensated by the 4-fold fluorescence modulation upon calcium complexation (which indicates a higher sensitivity of compound **15f** to calcium in comparison with the sensitivity of indicator **15b**). The introduction of a donor methoxy group improved the properties of indicator **15g**: the reduction of Φ_{fl} observed by a transition from the Ca-free form to the Ca-bound form was found to be a 13-fold already. The incorporation of electron acceptor groups in compound **15f** produced a significant decrease in the Φ_{fl} values of the free and bound form of indicators (for the fluorine substituent by a factor of two and for a nitro group by a factor of 500), that made the fluorescence signal of indicators **15h** and **15i** hard to detect. The replacement of the phenyl fragment with a thienyl ring in **15i** resulted in a compound **15j** without any detectable changes in the fluorescence signal upon calcium coordination. It was possible to apply

indicators **15f–j** in dual ratiometric modes, because these compounds had a pronounced shift in both spectral maxima; the most promising were compounds **15f–g**.

2.6. Crown-based calcium indicators

Like in the case of the charged chelators (BAPTA), the search for calcium sensors with crown-ether residues started from compounds analytical chemistry.^[69] Interestingly, the same connecting mode was used to bind the ionophore to the fluorophore. As in the case of Calcein, a Mannich reaction was applied for this purpose to provide compound **16**.

Figure 21. Fluorimetric crown ether reagent for calcium detection.^[69]

This sensor **16** showed a large shift in the UV band upon calcium complexation (from 326 to 380 nm). It was successfully used for the so-called “extraction-fluorimetric” method of calcium determination. This method involves the extraction of calcium from an aqueous medium with compound **16** to an organic solvent followed by measurements of the fluorescence signal of the organic solution. With this method, it is possible to assess the content of calcium on a ppb level.

Due to the success of the BAPTA-sensors, the development of the crown-containing Ca-sensors progressed fairly slowly. All known crown-containing sensors were designed for and studied in non-aqueous solutions (usually in acetonitrile). Most of the compounds of this class were not described as indicators, but as host compounds with some interesting sensing properties.

17a: X = CO;

17b: X = CH₂.

Figure 22. Calcium indicators with a 12-crown-4 as a coordinating moiety.^[70]

Only two calcium-sensing hosts with a 12-crown-4 ether as the main coordinating element has been reported.^[70] The two variants **17a-b**, absorbing in the UV region (at about 360 nm) were selectively sensitive to calcium, but not to other alkali and alkali earth metal cations. However, these compounds had relatively low fluorescence quantum yields (0.26 and 0.10, respectively). They have different fluorescence maxima (**17a**: 460 nm, **17b**: 412 nm), and opposite directions of the spectral changes upon calcium coordination: the first anthracene containing “host” **17a** displayed a two-fold decrease in the fluorescence signal, while the second **17b** produced a two-fold increase.

- 18a**: DS-crown: $R^1 = R^2 = H$, $n = 1$;
18b: DCS-crown: $R^1 = H$, $n = 1$, $R^2 = CN$;
18c: PDS-crown: $R^1 = H$, $n = 1$, $R^2 = Ph$;
18d: DDB-crown: $R^1 = H$, $n = 2$, $R^2 = NMe_2$;
18e: DDS-crown: $R^1 = H$, $n = 1$, $R^2 = NMe_2$;
18f: DDCS-crown: $R^1 = CN$, $n = 1$, $R^2 = NMe_2$.

Figure 23. Stilbene-based calcium indicators **18a-f**.^[71,72]

An attempt to use stilbene derivatives as potential fluorophores for calcium sensing was reported as early as 1985 by Tsien.^[35] However, because of the low fluorescence quantum yields and the photochemical side reactions, stilbene indicators were abandoned. Nevertheless, eight years later another research group investigated the photophysical properties of stilbene-containing dyes. In this study, it was discovered that the crown-ether containing stilbene **18a** produced a 20 nm blue shift of the emission maximum upon calcium complexation.^[71a]

Further research on this stilbene derivative and its analogues with different substituents resulted in two PCT sensors **18b-c** with high sensitivity to calcium.^[71b] The crown-containing “push-pull” compound **18b** and biphenyl compound **18c** have more attractive properties than the only donor-substituted compound **18a**. For example, the latter is poorly fluorescent ($\Phi_f = 1.3\%$ in acetonitrile), while these Φ_f values for compounds **18b** and **18c** were found to be 6 and 27 times higher, respectively. In addition, compounds **18b-c** display a 50 nm blue shift in

absorption maxima upon calcium coordination. However, their main absorption bands are in the UV region: $\lambda_{abs}^{max} = 385$ nm for the free ligand **18b** in MeCN, $\lambda_{abs}^{max} = 374$ nm for the free ligand **18c** in BuCN. Unfortunately, neither of these compounds showed sufficient selectivity for calcium in the presence of barium (e.g. $\ln K_s(\text{Ca}^{2+}) = 4.20$ and $\ln K_s(\text{Ba}^{2+}) = 3.74$ for **18b**). Besides that, a 2.2-fold decrease in the fluorescence quantum yield was found for **18c** upon calcium coordination, which is not optimal for a ratiometric probe.

The introduction of two donor groups into the stilbene core radically changed the spectroscopic properties of the “push-pull” sensors **18d-f** (see Figure 23).^[72] Upon calcium complexation, the azacrown moiety with a calcium cation inside acts as an acceptor, which causes a strong intramolecular charge transfer (ICT) from the dimethylamino group to the crown ether upon excitation with light. As a consequence of the ICT, a significant red shift in the fluorescence spectra results (upon complexation with calcium). The values of these shifts varied from 36 to 80 nm (**18d-f**). Surprisingly, the prolongation of the conjugation chain almost did not affect this shift ($\Delta\lambda_{fl}^{max}$ for compound **18d** was 43 nm vs. 36 nm for compound **18e**). However, the introduction of a nitrile acceptor group into the *ortho*-position to azacrown residue caused a two-fold increase of the shift, owing to the higher stabilization of the state with a negative charge on the aromatic ring. Such favorable changes in the fluorescence spectra upon calcium coordination enable one to use these substances in ratiometric measurements. Unfortunately, the absorption spectra demonstrated only small blue (**18e**: 7 nm, **18d**: 8 nm) or red (“unproductive”) shifts (**18f**: 2 nm). As candidates for calcium sensors, the stilbene derivatives have important drawbacks: a decrease in the fluorescence quantum yield for the calcium complexes from 2.1 times for compound **18f** to 10 times for **18e**, and the necessity of UV excitation (at 359–385 nm, for the free ligands and their complexes).

Figure 24. Calcium-sensitive fluorescent molecules with diaza-18-crown-6 chelation moieties.^[73a, 80]

A. Pearson and co-workers showed that diaza-18-crown-6 ether derivatives (Figure 24) are also applicable for calcium sensing.^[73a] By exploration of the PET effect in the series of dansyl amides (e. g. compound **19a** in Figure 24), a new highly selective calcium indicator – compound **19a** – was discovered. In this compound, the dansyl group plays the role of an electron acceptor, while the tetraalkyl-*p*-phenylenediamine (TAPD) residue with an incorporated crown ring is a strong electron donor. The sensor **19a** could be used for measurements exclusively in the fluorescence mode. It produces a strong increase in the fluorescence intensity upon complexation with calcium – 5.5 times (at $\lambda_{fl}^{max} = 540$ nm). The ratiometric mode in this case does not work, because compound **19a** provides only an 8 nm hypsochromic shift of the absorption maximum in the UV region (after complexation). It should be noted that **19a** has a low affinity for calcium ($\log K_s = 3.2$), and a low value of the fluorescence quantum yield (0.04).

Figure 25. Calcium sensitive fluorescent molecules with aza-15-crown-5 chelation moieties.^[74,75]

The first rational synthesis of a crown-based fluorescent calcium sensor, that of **20a** (Figure 25) was carried out by B. Valeur and co-workers in 1988.^[74] This styrene-containing indicator with a benzoxazinone fluorophore displayed a 20 nm hypsochromic shift in the absorption spectrum upon coordination with calcium and, as typical for a PCT sensor, a large (68 nm) blue shift (from 642 to 574 nm) of the fluorescence maximum. Besides that, metal complexation increased the fluorescence quantum yield (e. g. for Ca^{2+} : $\Phi_{\text{bound}} (0.64) / \Phi_{\text{free}} (0.33) = 1.9$). It may be insufficient for the direct fluorimetric measurements, but can be a good addition for the ratiometric properties. Compound **20a** had an insufficient selectivity for calcium in the presence of barium ($\log K_s(\text{Ca}^{2+}) = 4.14$; $\log K_s(\text{Ba}^{2+}) = 3.62$). However,

barium does not occur in living tissues in any significant amounts, and therefore compound **20a** may be used as a Ca^{2+} sensor there.

The replacement of the donor-acceptor type benzoxazinone chromophore with an acceptor – dicyanomethylene-4*H*-pyran – caused some drastic “mirror” changes in the photophysical behavior of respective indicator.^[75] The new sensor **20b** shows a strong 66 nm blue shift in its absorption spectrum upon calcium coordination. This shift, of course, makes ratiometric measurements possible. Upon increase in metal ion concentration, the fluorescence maximum in the spectrum of compound **20b** was only slightly shifted, and this was accompanied by a steep decrease of the fluorescence quantum yield (about 3 fold). As compared to **20a**, the stability constants of the new indicator did not change significantly ($\log K_s(\text{Ca}^{2+}) \approx 3.76$).

Scheme 5. The working principle of a transition metal complex indicator for calcium **21**.^[76]

An unusual sensor for calcium was described by McQueen et al.^[76] This indicator **21** is based on the rarely used principle that upon activation by light by means of a metal-to-ligand charge transfer (MLCT) it is transferred into the excited state **21**^{*}. This state has two possible relaxation paths: 1) return to the ground state with emission of light of frequency ν' or 2) internal conversion (IC) with electron transfer from the other ligand's donor atom to the metal. The nitrogen atom of the azacrown fragment in ligand A suits very well to provide the internal conversion. It was found that the coordination of a positively charged ion with the crown ether excludes the IC decay that results in the return of the excited molecule to the ground state with the emission of light. The highest increase in fluorescence and fluorescence quantum yield among various cations is produced by calcium (7-fold), although the absolute value of Φ_f is moderate, only 0.012, despite an excess of calcium. The position of the fluorescence maximum was found to be at 600 nm, and remained unshifted, while the absorption maximum shifted by 45 nm (to 305 nm) upon complexation with calcium.

Figure 26. Calcium sensors with an aza-15-crown-5 ether moiety in a chelator role.^[77]

An absolutely new fluorophore, 2-phenylimidazo[5,4-a]anthraquinone (R^1 , Figure 26), emitting and absorbing in the visible region with $\lambda_{abs}^{max} = 405 \text{ nm}$ and $\lambda_{fl}^{max} = 515 \text{ nm}$, was used to construct the PET chemosensor **22a**.^[77] This compound demonstrated a maximum value of the stability constant for its complex with Ca^{2+} ($\log K_s = 6.51$) and a maximum enhancement of the fluorescence quantum yield upon calcium coordination, in comparison with other alkali and alkaline earth cations. However, the low value of its fluorescence quantum yield ($\Phi = 0.7\%$) and low selectivity for calcium in the presence of magnesium and barium, do not favor the application of compound **22a** for calcium determination. The low selectivity is reflected in the small difference between the stability constants for Mg^{2+} , Ca^{2+} , Ba^{2+} (not higher than one logarithmic unit).

Scheme 6. Graphical demonstration of the ESIPT effect as exemplified for the compound DMHN (1-[(diethylamino)methyl]-2-hydroxy-3-naphthaldehyde).^[78b]

A promising calcium sensor (compound **22b**, Figure 26) based on the highly fluorescent 3-hydroxynaphthalene-2-carbaldehyde was prepared.^[78a] Its dialkylaminomethylene derivative – the famous solvatochromic compound DMHN (Scheme 6) – showed significant red shifts ($\approx 100 \text{ nm}$) in the excitation and emission maxima upon increasing solvent polarity. Such spectral changes occurred due to an excited state intramolecular proton transfer (ESIPT).^[78b] Instead of the two ethyl groups, the novel indicator **22b** had a crown-ether ring.

Undoubtedly, the ESIPT effect largely influences the photochemical and photophysical behavior of compound **22b**. This effect is also displayed in the total switch from yellow (585 nm) to the near-infrared emission at 730 nm in the presence of high sodium concentrations, and in a 20 nm shift in the emission maxima upon calcium complexation. However, the main factor that explains the changes in fluorescence upon metal-ion coordination could be PET. Obviously, the PET effect takes place in **22b**, as well as in other crown sensors (like **22a**, **19**, **17** Figure 26, 24, 22). However, because of the presence of the acidic phenol hydroxy group in compound **22b** (which decreases the efficiency of the electron transfer from amino group) the PET-effect is not very pronounced. Therefore, it becomes possible to explain the opposite directions in fluorescence changes observed upon metal-ion coordination with compound **22b**. Owing to the presence of the crown ring, sodium binds with the lone electron pair of the nitrogen atom better than a proton. However, Na⁺ does not suppress PET as effectively as a proton. The overall result of sodium binding is a decrease in fluorescence intensity at 585 nm. The opposite effects were observed in the case of calcium: the doubly charged calcium suppresses the PET effect better than a proton. The result of the PET-effect suppression is an increase in fluorescence intensity upon calcium complexation. Thus, having the same stability constant ($K_s(\text{Ca}^{2+}) = 3.8 \times 10^4$; $K_s(\text{Na}^+) = 2.3 \times 10^4$) and the opposite effect on fluorescence, it is possible to use compound **22b** as a calcium sensor, though only in the absence of sodium, and with accurate pH control (in analogy to DMHN, the compound **22b** is sensitive to the pH value).

Figure 27. Calcium indicator with a *p*-aminobenzanilide fluorophore.^[79]

A simple fluorophore fragment – *p*-aminobenzanilide – was utilized by Liu et al. for the creation the alkali and alkaline earth metal-ion sensors.^[79] The functional principle of these indicators is relatively simple: in the free state, compounds **23a-c** have the D-A-D' sequence (D – electron donor, A – electron acceptor). At the same time, one of the terminal donor components is a 15-crown-5 ether with two oxygen atoms, participating in conjugation with the benzene ring. This sequence changes to D-A-A' upon cation complexation (including calcium), because the metal ion has high electron-withdrawing properties. Also, the presence

of two interacting centers, the oxygen atoms attached to the aromatic ring, instead of one nitrogen atom (as it was in most of the crown sensors described above), influences the spectroscopic properties. The changes in the electron density distribution upon Ca^{2+} coordination were a slight red shift in the absorption maximum (from 320 to 324 nm for **23b**) and a dramatic increase in both fluorescence maxima (at 373 and 497 nm for compound **23a-c**) with a leap in fluorescence quantum yield (up to 22.7-fold for the complex of compound **23b** with calcium). Only the short wavelength fluorescence maximum had a red shift up to 25 nm (for the complex of compound **23a** with calcium). However, as has already been mentioned above, such an indicator is not of any interest for the area of research addressed here, i. e. cells and their components. The main features that make its applications for such purposes impossible are: a) excitation and emission bands in the UV region; b) similar stability constants for the complexes with other biologically relevant metal ions ($\log K_s(\text{Ca}^{2+}) = 5.54$; $\log K_s(\text{Mg}^{2+}) = 5.58$); c) extremely low absolute values of Φ_f ($< 1\%$).

In the early work of Pearson et al.^[73] some aza-18-crown-6 ethers (only the best sensor from this series **19a** is presented in Figure 24) with a suitable selectivity for calcium were reported. Later on, in combination with an anthracene residue as a fluorophore, a series of new calcium indicators were prepared (compound **19b-e**, Figure 24).^[80] The simplest compound **19b** is 11 times more sensitive and 5 times more selective than the BAPTA analog **QCa-1**. This improvement may be explained by the direct attachment of the sensitive nitrogen atom to the fluorophore (in contrast to **QCa-1**, in which the aromatic ring is inserted between them). Due to the presence of an anthracene fluorophore, compound **19b** has the same moderate fluorescence quantum yield (0.20) as **QCa-1**. As regards the coordinative ability, compound **19b** has a stability constant (K_s) which is two orders of magnitude higher than that of the analogue **19a**. Variation of the substituents at the remote nitrogen atom seriously changed the sensitivity (up to an 8-fold increase for compound **19c** in comparison with **19b**) and influenced the selectivity for calcium over magnesium (up to 7.3-fold decrease for **19e** in comparison with **19b**).

2.7. Calixarene hosts as coordination moieties for calcium sensors

Quite recently, calixarenes – a very special class of host compounds – became good candidates in the wide variety of new calcium sensors.

Figure 28. Calcium sensors with calix[4]arene moieties as chelators.^[81,82]

Calixcrowns (e. g. compound **24a**, Figure 28) – a special class of macrocyclic compounds – were prepared by incorporation of the crown ether fragments to the opposite sides of calix[4]arene.^[81] The heteroatoms of the lariat crown ether and pendant groups (in the current case carbonyl oxygens) form a three-dimensional net of binding sites, which can effectively catch cations with suitable ion radii. Calcium ions cause two types of changes in the spectroscopic parameters of compound **24a**: a) a red shift in the absorption (18 nm) and emission bands (34 nm) owing to the typical PCT-sensor behavior upon coordination to oxygen atoms of the (acceptor) carbonyl groups; b) 4.5-fold increase in fluorescence intensity. The latter change may be explained considering that the fluorophore molecule is prevented from self-quenching of the fluorescence of the two naphthalene fragments, as they are moved apart upon coordination of **24a** with calcium. Unfortunately, all studies were carried out in acetonitrile only. Besides that, the sensor **24a** had an absorption maximum in the UV region (310 nm), and the fluorescence band was found at the edge of the visible region, i. e. at 400 nm.

Two very similar calixarene sensors were investigated by Korean and American researchers.^[82a,b] The first sensor – compound **24b**^[82a] – is more water-soluble (due to the presence of two carboxylic acid groups). It has an additional methylene group between the pyrene ring and the amido group. The second sensor **24c**^[82b] has *N,N*-diethylcarboxamido groups instead of the carboxylic acid functions, and the amido fragment is directly attached to the pyrene ring. To provide sufficient ion complexation ability, both compounds were decorated with four bulky *tert*-butyl groups fixing the required positions of the phenolic oxygen atoms in space. The other group of heteroatoms was required “to wrap” the metal ion more tightly. This set consisted either of the two amide nitrogen atoms and two carboxylic

acid oxygen atoms in the case of compound **24b**, or only of the amide nitrogen atoms (for compound **24c**). For compounds **24b-c**, the principle of sensing was different from that of **24a**, although the calcium coordination also caused a conformational change of the pendant group (in this case, the pyrene fragments). This kind of spatial rearrangement produced other photophysical changes, such as a decrease in the intensity of the intramolecular excimer emission band at 480 nm and, at the same time, an increase in the intensity of the monomer emission band at 397 nm. The changes of the fluorescence intensity ratios of the monomer-excimer emission (I_M/I_E) of **PyCalix** varied from 2.4 to 12.2 (in the range of calcium concentration 10^{-7} – 10^{-5} M); the stability constant of the calcium complex with sensor **24c** being 1.4×10^6 . As concerns compound **24b**, a PET process may also partially explain its sensitivity mechanism, because of the presence an additional methylene group between the pyrene ring and the amido group in compound **24b**.

2.8. Podands as a coordination moiety for calcium sensors

Upon coordination with calcium cations, open-chain polyethers change their molecular geometry and their photophysical properties. These changes can be employed in the evaluation of such ion concentrations.

Figure 29. A ruthenium complex which is sensitive to the presence of calcium.^[83]

Compound **25** was one of the first podand calcium indicators. It represents a highly water-soluble ruthenium complex.^[83] Initially, it was created not as a sensor and, therefore, the sensitivity for calcium was poorly investigated. The complex **25** showed a satisfactory increase in fluorescence intensity (1.3 times) upon calcium saturation (at 0.65 mM). The selectivity of compound **25** for calcium was very high (in comparison with other cations). For example, the stability constant of the calcium complex was 100 times higher than the stability constant of the complex with magnesium.

Figure 30. Calcium sensors with open-chain polyether moieties as chelators.

Another sensor **26a** (Figure 30), was reported by Kakizawa et al.^[84] Upon calcium complexation, compounds **24c** and **26a** have the same fundamental states (monomer and intramolecular dimer). In the presence of calcium, the latter compound transforms itself from a monomer (emission maximum 400 nm) to an intramolecular dimer (em. max. 490 nm), i. e. in the opposite direction than compound **24c** does. It is possible, because the main conformation of the molecule **26a** in solution is stretched and, upon complex formation this molecule “coils up”, so that the anthracene residues oppose each other. In this state, compound **26a** can very easily form an inner excimer upon light excitation. Along with the red shift, an 8-fold decrease in fluorescence intensity of the short wavelength band and a simultaneous 8-fold enhancement of the long wavelength band were observed. However, the selectivity of this indicator is not very good: the value of the stability constant for the calcium complex is only 3.5 and only 5 times higher than those for strontium and magnesium, respectively.

The performance of compounds **26b-c** (see Figure 30) is based on the same principles, as that for compound **26a**. The influence of the polyether chain length and the nature of chromophores on the fluorescence response upon metal-ion coordination were reported.^[85] It was found that only calcium and barium increase the intensity of the maxima of the excimer bands (at 400 nm for **26b** and 415 nm for **26c** in the case of Ca^{2+}) and, at the same time, decreased the intensities of the monomer bands (at 360 nm for both sensors) by the same order of magnitude (2–3 times). A higher fluorescence intensity was observed in the case of a 2-naphthalenecarboxy chromophore present (compound **26b-c**) in comparison with the 1-naphthalenecarboxy analogue (not shown). The reason is that the carboxy groups in the α -substituted naphthalene fragments are twisted, and the conjugation is perturbed. The stability constants were higher for the longer chain with the β -naphthalene chromophore ($\log K_s(\mathbf{26b}) = 4.19$; $\log K_s(\mathbf{26c}) = 4.95$).

Figure 31. The podand **27**.^[86]

Another compound of this class is the terthiophene Dendron **27** with a tetraethylene glycol coordination residue, which was described in 2008.^[86] The indicator **27** has two absorption bands, one at 300 and one at 350 nm, respectively. These bands do not change their positions in the presence of calcium. The spectrum of compound **27** has one fluorescence band at 460 nm. This band undergoes a significant blue shift (to 320 nm), and its intensity strongly increases upon calcium coordination (ca. 6 times). According to the interpretations of the authors, the addition of calcium salts produces a “twist” of the thiophene units within the chromophore moiety to form a complex with the cation. As a result, the large conjugated system shrinks to a smaller one, which is much more fluorescent and emits in the UV region.^[86]

Chapter 2. Synthesis and properties of new fluorescent calcium sensors

1. Search for an optimal coordinative part and its position within the phenylxanthene backbone

The choice of the target structures for our research was based on their required properties and the detailed analysis of the available literature data. During the 35 years that passed from the first publication on the application of calcium indicators in biological research, more than a hundred new compounds have been created. All of these substances are sensitive to calcium. However, it is well known, that is impossible to use only one indicator for various applications. Therefore, it is often necessary to prepare new indicators for special purposes. Moreover, new research methods and objects in molecular biology require calcium indicators with novel properties. The required properties of the calcium sensors applicable in optical nanoscopy are:

- 1) excitation and emission maxima in the region above 450 nm;
- 2) a “switching” possibility (e. g. due to the presence of a free carboxy group on the phenyl ring in the *ortho*-position to the xanthene fragment);
- 3) a high “brightness” of the dye (brightness is the product of the fluorescence quantum yield and extinction coefficient);
- 4) a certain sensitivity to calcium ion;
- 5) an ability to penetrate cell membranes;
- 6) a high photostability.

We will briefly recall the properties of the most “prominent” compounds from chapter 1 and discuss, if they correspond to the requirements mentioned above. Furthermore, we will show that the use of some known structural fragments in our own synthetic approach led to new target structures.

Each calcium indicator should be sufficiently water-soluble (as it has to “work” in an aqueous medium in the cell). The prominent sensors with BAPTA coordination moieties are soluble in water, because they contain carboxy groups in their coordination moieties. APTRA-indicators, with three carboxy groups in the coordination moiety, are also well enough water-soluble. However, the solubility in water of most of the crown ether-containing indicators is not very high. Two of them (**16** and **22b**) contain a phenol residue, which increases the solubility (but only very slightly). Among the calixarene sensors, compound **24b** possesses two carboxy groups (and therefore, it is well soluble in water). One of the podand

sensors **25** is hydrophilic. However, it is not possible to consider compound **25** as a leading structure for construction of novel sensors for biological research, because it is a complex of a heavy metal – ruthenium. As in the case of the BAPTA chelators, we have chosen carboxy groups as structural fragments, which not only increase hydrophilicity, but also provide additional coordinative properties.

Another important prerequisite is the necessity to apply visible light in experiments with cells, because UV light can damage organic compounds in the cells. Moreover, UV light produces an (auto) fluorescence background due to the emission from the nucleic acids and proteins. In the case of the BAPTA sensors, this problem was solved by careful choice of the fluorophore (optimized for compounds **5b-g**, **6a-z**, **6aa**, **9a-h**, **11c-e**, **12**, **13**, **14a,b** representing more than half of the BAPTA sensors). Xanthenes are the most popular fluorophores (e. g. rhodamines, fluoresceins, rhodoles) among the sensors mentioned above. Other classes of indicators (with an APTRA chelator) contain only ca. 1/3 of the substances which emit upon excitation with visible light: e. g. **15c** (with the diarylpyrrolo[3,4-*c*]pyrroldione core) and **15d-e** (with the BODIPY[®] core). The main sensors with crown ether, with calixarene and with podand chelators are *a priori* not suitable for work in biological media, as only some indicators absorb in the visible region: e. g. **20a** (stilbene with a benzoxazinone substituent), **20b** (stilbene with a dicyanomethylene-4*H*-pyran substituent).

In this work we used the most popular 9-phenylxanthene fluorophore which is easily synthesized and modified (Figure 32).

Figure 32. 9-(2-Carboxyphenyl)xanthene fluorophore of the present work (X,Y = O; X = O, Y = N; X,Y = N).

The presence of a carboxy group in the *ortho*-position of the phenyl ring attached to the xanthene backbone is very important, as this group provides the switching possibility.^[5] Xanthene derivatives are found only in the BAPTA series of indicators. The potentially interesting compounds from which the photosensitive spiroamides^[5] or spirodiazaketones^[6] may be obtained are the BAPTA-indicators **6x**, **9a-f**, **9h**, **11d-e**. As a basic chromophore structure, all these indicators have a fluorescein (not rhodamine) residue. Though there are

some methods for the preparation of spiroamides from fluorescein,^[87] but there is no guarantee, that these methods will be applicable for specific sensors.

Another important property is "the brightness" of a fluorescent sensor. In most cases, we refer to the values of the fluorescence quantum yields, because the extinction coefficients were found to be similar (ca. $1\text{--}3 \times 10^4 \text{ M}^{-1}\text{cm}^{-1}$). Only a small part of the Ca sensors mentioned above have fluorescence quantum yields higher than 60%. Such kind of sensors were referred to as green-emitting series (**9a-h**, **11d-e**) and crown ethers (**20a-b**). Fluorescein and rhodamine are the chromophores of the "Green" series, the fluorophores of crown ether-containing indicators are based on stilbenes with donor-acceptor pairs. In order to choose either fluorescein ($X = Y = \text{O}$), or rhodol ($X = \text{O}$, $Y = \text{N}$), or rhodamine ($X = Y = \text{N}$) as a basic fluorophore (Figure 32), we have to consider another important prerequisite – the required fluorescent response upon calcium coordination. There are two kinds of this response: a) change of the fluorescence intensity; b) shift of the excitation and/or emission maxima. The best sensors (e. g. **4a** or **5a**) have a dual (a+b) response. The type of the response depends on the working mechanism of the sensor (see section 2.1). There are PET sensors which increase or decrease their fluorescence intensity upon calcium coordination, and PCT sensors which are characterized by a shift of the maxima (sometimes accompanied by changes in the fluorescence intensity), as well as sensors with intramolecular formation / dissociation of excimers (drastic changes in the maxima positions). Among the BAPTA indicators, the PET sensors are **Quin-2**, **6a-z**, **6aa-ab**, **9a-h**, **10a-c**, **11a-e**, **13** and the PCT sensors are **4a-e**, **5a-o**, **7a-k**, **8a,b**, **12**, **14a,b**. Among the APTRA sensors, the PET compounds are **15a,b,d,e**, while **15f-j** are PCT compounds. Among the crown ethers, there are nearly equal amounts of PET (**16**, **17a-b**, **19a-e**, **23a-c**) and PCT sensors (**18a-f**, **20a-b**, **22a-b**). Practically all calixarene indicators are based on the same sensing principle – the intramolecular excimer dissociation, and the podand indicators are based on an intramolecular excimer formation. It is interesting to note that the maximal increase in the fluorescence signal (in the case of PET sensors) was found for compound **11b** (180 times). The greatest shift of the position of the fluorescent maxima (in the case of PCT sensors) was found to be 80 nm (for compound **18f**). Compound **14a**, with its highly fluorescent xanthene fluorophore, enables one to achieve a shift of both the excitation and emission maxima upon Ca complexation (whereas most indicators with xanthene fragments only increase their fluorescence intensity). Therefore, we can define the heteroatoms X and Y for our target structures in Figure 32, as O and N, on one hand, and N,N, on the other hand (Figure 33).

Figure 33. Rhodol (**I**) and rhodamine (**II**) as lead structures for creating new Ca sensors.

Most of the BAPTA indicators always possess good selectivity for calcium. The APTRA chelator, with its lower coordination number and only one nitrogen atom instead of two N-atoms in BAPTA, is characterized by a lower selectivity to calcium (i. e., compound **15b** has the same K_D values for Ca- and Mg-ions). In fact, all indicators, with only crown ether residues as a coordination part, are not selective for calcium. However, for the vast majority of biological applications, it is enough to have an indicator with high selectivity for calcium in the presence of other biologically relevant cations (Na^+ , K^+ , Mg^{2+}). Thus, the three known compounds **18b** and **20a-b** are suitable as lead structures for our requirements, though they are also sensitive to barium cations (which are absent in biological samples). In the series of calixarene sensors, it is known that compound **24b** is equally selective for calcium and strontium. One of the podand sensors (**26a**) is known not to be selective for calcium, and another two (**26b-c**) have similar stability constants for complexes with calcium and barium (which is acceptable).

To define the coordination moiety more accurately, we have to consider one more requirement. The dissociation constant of the calcium-indicator complex has to be higher than 90 μM . This prerequisite is especially important for an investigation of calcium spikes by the STED microscopy. Indicators with lower K_D values would have been saturated long before the calcium level reaches its maximum value. Thus, indicators with lower K_D values could give inadequate results. From the whole family of BAPTA indicators, only compound **7e** has a satisfactory K_D value of 550 μM . Among the APTRA sensors, there are already two suitable compounds **15d-e** ($K_D \approx 100 \mu\text{M}$). The crown ether indicators contain three compounds with K_D values of more than 90 μM (**18b** – 15 mM, **19a** – 630 μM , **20b** – 174 μM). All Ca indicators with calixarene and podand coordination moieties have dissociation constants lower than 90 μM . Therefore, the coordination site shown in Figure 34 was chosen as a starting point for our novel Ca sensors.

Figure 34. Coordination site for novel Ca sensors to be prepared.

The photostability of the fluorophore is important especially in the case of STED nanoscopy, where the excited state is depleted with a high-power laser. Xanthenes were the most photostable fluorophores used in the BAPTA indicators. The best APTRA indicators **15d-e** were constructed with BODIPY[®] fluorophores which are more photostable than fluorescein.

Penetration through the cell membrane is another very important factor which plays a key role in the design and optimization of the new calcium sensors. As it was mentioned in section 2.4 of the Chapter 1, the BAPTA indicators (and probably also the APTRA sensors) pass through cell membranes, if their negatively charged COO^- groups are converted to neutral acetoxymethyl esters, the phenolic OH groups are acetylated, and the sterically hindered carboxy group in the *o*-position to the xanthene ring forms the internal 5-membered lactone. This extensive acetoxymethylation removes all negative charges, the presence of which slows down the transport through a cell membrane. Deesterification is achieved inside a cell by action of enzymes (e. g. esterases). For other indicators this problem may be solved similarly (if they contain carboxy groups). To increase the permeability of one of our target compounds we used methyl groups (not ethyl groups) at nitrogen atoms (see Figure 35). It is known that tetramethylrhodamine derivatives pass through cell membranes easier than the derivatives of rhodamine B.

Figure 35. Tetramethylrhodamine as a building block for the sensor **II**.

To form the final structures, it is necessary to connect or fuse the fluorophore (xanthene) and the ionophore (azacrown). To distinguish between connection and fusion, we consider the compounds **29** (in which the crown ring connected with the benzene ring via one heteroatom) and **28** (in which two heteroatoms of the crown ether are connected with the benzene ring).

Figure 36. Azacrown ethers **28**, **29**.

As it was mentioned in the section 2.6 of Chapter 1, upon coordination to the crown ether ring, the electron-withdrawing properties of the calcium cation, cause various spectroscopic changes (e. g. shift of the positions of the absorption and fluorescence maxima or increase/decrease of their intensity). Due to the calcium coordination, the electron density on the aromatic system connected with heteroatoms is reduced. Obviously, if we bind the calcium cation with two heteroatoms (compound **28**), the changes of the electron density on the aromatic system will be stronger, and therefore, the spectroscopic response has to be stronger.

There are several possible positions at which the xanthene core may be fused with the crown-ether system. However, not all of them are readily available. For example, fusion through the positions 1,2 (7,8) and 6',7' are unfavorable, because the positions 1(7) and 7' are sterically hindered (see Figure 32), and it is very difficult to integrate a crown ether using one of these positions. In the case of the target sensor **I**, positions 2(7), 3, 4(5), and 4', 5', 6' are available for the fusion with the crown ether macrocycle. We fused the crown-ether residue with the xanthene core through the positions 6 and 7 of the latter. As a model compound, we used the sensor **14a** in order to provide similar spectroscopic changes (the shift of the fluorescence spectrum maximum) upon complexation with calcium.

Figure 37. Incorporation of the crown-ether moiety into the sensor **I**.

Another argument in favor of the structure **I** (as a model compound, see Figure 37) is the simplicity of the synthetic procedures compared to those associated with other substitution patterns of the xanthene backbone.

The second type of a target sensor compound **II**, is presented in Figure 38. The crown ether residue is fused with the positions 4' and 5' of the phenyl ring attached to the xanthene fragment. The main reason for choosing this kind of substitution pattern is the availability of compounds with 1,2,4,5-tetrasubstituted phenyl rings in comparison with 1,2,3,4-substituted benzene rings.

Figure 38. Incorporation of the crown ether residue into sensor **II**.

An important feature is the nature of the substituents at the nitrogen atom of the azacrown ether ring. It is well-known, that the presence of NH-groups (but not NR-groups) makes the azacrown ether (Figure 38) less susceptible for coordination with calcium cations.^[88] Therefore, we prepared indicators with an ethyl group (compounds **Ib** and **IIa**) and sensors with a carboxymethyl residue (compounds **Ic** and **IIb**). The carboxymethyl group has two important properties: a) it represents an additional coordinative site which may increase the selectivity to calcium; b) it substantially increases the solubility in water. An additional carboxy group in the phenyl ring attached to the xanthene fragment also increases the hydrophilicity. We prepared the model compound **Ia** for comparison, though this substance is deprived of an additional substituent at the nitrogen atom.

Figure 39. Target sensors **Ia-c**, **IIa-b**.

2. Model compounds

Before we embarked on the synthesis of target compounds **1a-c**, we had prepared some model compounds: a) a rhodamine with an alkoxy substituent in the *ortho*-position to the amino group; b) spiroamides with a "closed" rhodol fragment (cf.: [5]).

A conventional synthetic route to rhodols with a carboxy group starts with an acylation of resorcline or *m*-aminophenol with phthalic anhydride (**30**) followed by the reaction with a second molecule of *m*-aminophenol or resorcline (see Scheme 7).

Scheme 7. Various synthetic routes towards xanthene dyes.

3-(*N,N*-Diethylamino)-4-methoxyphenol (compound **31** in Figure 40) was prepared as a model compound from the commercially available acetanilide **32** which was deacetylated by heating in aqueous HCl under reflux.

31

Figure 40. Model compound **31**.

The aniline **33** was obtained in good yield and then diazotized. The aryldiazonium hydrogen-sulfate **34** could be converted into the phenol **31** only by prolonged boiling in

aqueous solution.^[89] Other methods (adding of the diazonium solution into the boiling 67% sulfuric acid,^[90] or decomposition in the presence of $\text{Cu}(\text{NO}_3)_2$ and Cu_2O ^[91]) failed to provide the required phenol **31**.

Scheme 8. A successful route to the phenol **31**.

The phenol **31** was used for the preparation of rhodamine **35** (Scheme 9). Unfortunately, the yield of the dimethoxyrhodamine **35** was only moderate (18%). As a rule, conventional condensation methods require harsh reaction conditions for the second step (Scheme 7): high temperatures (up to ca. 200 °C) and strong acids (e. g. phosphoric acid, 50% aq. sulfuric acid). For the model reaction (compound **30** + compound **31**) the mildest conditions were used: heating overnight in refluxing propionic acid with *p*-TosOH•H₂O as a catalyst.^[92]

Scheme 9. Synthesis of rhodamine **35**.

In order to check the possibility of synthesizing spiroamides from rhodols compounds **39**^[93] were prepared according to the known method.^[93] Towards that end, 3-*N,N*-diethylaminophenol **36** was acylated with phthalic anhydride **30** in a non-catalytic Friedel-Crafts reaction to produce the benzophenone derivate **37** in good yield. The next step was the reaction of resorcinol **38-H** with the benzophenone **37**, and this was succeeded by an intramolecular condensation of the intermediate product at high temperature under acid catalysis, yielding 83% of rhodole **39-H**.

Scheme 10. Synthesis of the model rhodoles **39-H** and **39-Me**.

For preparation of the other model compound – the rhodole spiroamide **40-H** – the carboxy group in compound **39-H** would have to be converted it into the corresponding acid chloride,^[5] which is impossible due to the presence of the free hydroxy group that may react with an acid chloride or may even be converted into the corresponding aromatic chloride (see Figure 41).

Figure 41. Possible product upon treatment of compound **39-H** with phosphorus oxychloride (POCl_3).

To circumvent this problem, compound **39-Me** was prepared (Scheme 10) and successfully converted into the acid chloride **41-Me** (Scheme 11). The latter reacted with aniline and, in the presence of Et_3N , gave the spiroamide **40-Me**. Boron trichloride was used to remove the methoxy group^[94] to yield the required spiroamide **40-H** (Scheme 11).

Scheme 11. Synthesis of the rhodole spiroamide **40-H**.

2.1. Spectroscopic properties of the model compounds

For the model compound **35**, interesting spectroscopic properties were observed. The fluorescence quantum yield of this compound was found to be only 4.5% in ethanol and 0.9% in aqueous solution. These values are much lower than those for the similar compound without methoxy groups – Rhodamine B (65% in EtOH and 31% in water).^[95]

Figure 42. The structures of Rhodamine B and compound **35**.

A sharp decrease in the fluorescence quantum yield may be attributed to the higher rotational dissipation of energy of the molecule in the excited state. The methoxy group in the *o*-position of the diethylamino group could assist the rotation of the diethylamino group from being coplanar with the aromatic ring into an out-of-plane conformation. Therefore, the fraction of the non-radiative de-excitation processes becomes higher, and then the quantum yield decreases.

Figure 43. Absorption and fluorescence spectra of compound **35** in ethanol (black lines, $\lambda_{abs}^{max} = 570$ nm, $\epsilon = 66500$ M⁻¹cm⁻¹, $\lambda_{fl}^{max} = 596$ nm) and in water (red lines, $\lambda_{abs}^{max} = 568$ nm, $\epsilon = 47000$ M⁻¹cm⁻¹, $\lambda_{fl}^{max} = 604$ nm).

The absorption and emission spectra of compound **35** show bathochromic shifts in comparison with those of Rhodamine B (in ethanol: $\lambda_{abs}^{max} = 542$ nm, $\lambda_{fl}^{max} = 568$ nm, in water: $\lambda_{abs}^{max} = 553$ nm, $\lambda_{fl}^{max} = 581$ nm), which can be attributed to the presence of the donor methoxy group.

To check the photoswitching ability of the second series of model compounds **40-H**, the samples were illuminated with UV light, and then the emission spectra were recorded.

Figure 44. Emission spectra of compound **40-H** in toluene (excitation wavelength: 520 nm). Black line: sample stabilized in the dark; Red line: sample irradiated for one minute with UV

light, selected with a band-pass filter centered at 366 nm (UG1 – 3 mm, Schott); blue line: sample allowed to relax in the dark for one minute.

The emission maxima of the open form of the rhodole spiroamide **40-H** was observed at 546 nm. The efficiency of the opening reaction of the rhodole spiroamides was very low, and the thermal reclosing was fast. Only in toluene, the closing reaction was slow enough, so that it was possible to accumulate the open form with prolonged irradiation; but the amount of the open form was still very low. Nevertheless, the switching possibility for this kind of compounds was confirmed.

3. Synthesis of rhodole derivatives with a crown-ether moiety fused with the xanthene fragment

A retrosynthetic analysis reveals that the skeleton of compounds **Ia-c** may easily be constructed from phthalic anhydride **30**, resorcinol **38-H** and the phenols **42a-c** (see Scheme 12). These components should be combined sequentially (see Scheme 7).

Scheme 12. A retrosynthetic consideration of the target structures **Ia-c**.

3.1. Synthesis of the phenol building blocks via the unfunctionalized crown ether

There are two principally different synthetic routes to compounds **42a-c**. The azacrown ring may be constructed first, and then the hydroxy group (or a precursor of it) may be

introduced into the aromatic ring (Scheme 13). Another option is to use a precursor with a hydroxy group (or its equivalent), and then built up the crown-ether ring.

Scheme 13. Synthesis of the anilines **48a** and **48b**.

The azacrown **45** was prepared from *o*-aminophenol (**43**) and tetraethyleneglycol ditosylate **44** according to a known procedure.^[96] For the introduction of the hydroxy group into the aromatic ring of compound **45**, the latter was first converted into the *N*-nitrosoamine **46**.^[97] However, under conditions which provided the full conversion of amine **45**, an unseparable mixture of two *C*-nitroso compounds (**47a** + **47b**) was formed. Obviously, in the course of this transformation, a rearrangement of the *N*-nitrosoamine into the *C*-nitroso derivatives took place. This rearrangement was found not to be regioselective.^[97] Reduction to the corresponding amines did not help to separate the regioisomers **48a** and **48b** (the target compound **42a** is formed only from compounds **48a** via **48c**). Therefore, we did not pursue this route any further.

3.2. Attempted synthesis of phenol building blocks via the crown ether prepared from 2-amino-4-nitrophenol

As we failed selectively to introduce the functional group into the required position of azacrown **45**, we decided to construct the macrocycle starting from *o*-aminophenol with a functional group in the required position.

Scheme 14. An approach towards phenol **42a** via the nitrobenzocrown **51**.

Under the conditions of the successful preparation of the azacrown **45**,^[96] the desired macrocycle **51** could not be detected in the reaction mixture from compound **49** (Scheme 14). Under more drastic conditions (NaOH in *n*-butanol at 120 °C),^[97] the yield of compound **51** was found to be very low (2.7% after 18 h). The maximal conversion of the initial aminophenol **49** was found to be 18% (with 2 equiv. of Na₂CO₃ as a base in DMF at 90 °C). The preparative yield of the product (**51**) was only 6.3%. Several hundreds of mg of compound **51** were prepared and reduced to the aniline **48a** with hydrogen over palladium on charcoal. The aromatic amine **48a** was converted to the diazonium hydrogen sulfate **48c**, which was heated in aqueous solution at 70 °C. Unfortunately, the required phenol **42a** was not detected in the reaction mixture. This route was not pursued any further, because the key intermediate **51** could not be prepared in an acceptable yield.

3.3. Synthesis of the phenol building blocks by a ring-closing reaction of a tetraethylene glycol precursor

Complications associated with the presence of the nitro group in the aromatic ring (prone to vicarious nucleophilic substitution), should be avoided and therefore, each synthetic step should involve only one active nucleophile and one active electrophile.

Scheme 15. Synthesis of the protected tetraethylene glycol building block **54-Ac**.

To generate a precursor for the crown-ether ring, tetraethylene glycol (**52**) was converted to the monochloride **53**,^[98] and then to acetate **54-Ac** (Scheme 15) with a good leaving group on one end and an appropriate protecting group on the other end.

Scheme 16. Synthesis of the nitro phenol **58** as a second building block.

For the second building block, hydroquinone (**55**) was dibenzylated, mono-nitrated, and then the benzyl group at the oxygen atom in the *o*-position to the nitro group was selectively removed (Scheme 16).^[35b]

Scheme 17. Synthesis of intermediate product ditosylate **61**.

The building blocks **54-Ac** and **58** were combined according to Scheme 17. Alkylation of the potassium salt of the nitrophenol **58** (produced *in situ* from equimolar amounts of potassium *tert*-butoxide and compound **58**) with the chloride **54-Ac** was carried out in the presence of potassium iodide as a catalyst. The nitro group of the obtained product **59** was reduced,^[8] and the acetoxy group was cleaved in a one-pot reaction with hydrazine in the presence of Raney-Ni. This transformation provided the amino alcohol **60a** (95%). The latter was treated with tosyl chloride in pyridine, and thus the ditosylate **61** was obtained in 68% yield. Attempts to increase the yield by using DMAP as a catalyst or by a step-wise tosylation, failed.

Scheme 18. The final steps in the preparation of the phenol **42a**.

It is known from the literature, that under basic conditions tosylates may alkylate tosylamides to form *N*-tosyl derivatives of the secondary amines.^[99] These regularities allowed to perform a ring-closing reaction and obtain the *N*-tosylated crown ether **62**. The detosylation was carried out under mild conditions^[100] (see Scheme 18), because the recommended conditions (conc. H_2SO_4 , 100°C , 12 h)^[99] are too harsh and would destroy the crown ether ring. Finally, compound **63a** was debenzylated by the catalytic hydrogenation over palladium to give the target phenol **42a** in nearly quantitative yield. Acetic acid was used as a solvent,^[101] in order to prevent deactivation of the catalyst by the liberated amine **42a**.

Scheme 19. Alternative way to the crown ether **63a**.

An alternative route to the crown ether **63a** (Scheme 19) would start with a cyclization of the monotosylate **60b**. A potential advantage of this approach would be to avoid the tedious detosylation step. However, already the first step of this two-step sequence yielded only 16% of the monotosylate **60b**. The second step turned out to also be low-yielding (29%), so that the total yield was only 5%, which is much less than the total yield in the longer sequence (23%).

Scheme 20. Preparation of the *N*-ethyl derivative **42b** of the crown ether with a free OH-group.

For the synthesis of Ca sensors, we also needed the precursor **42b** with an *N*-ethyl group and an unprotected phenolic hydroxy group. The direct alkylation of the starting compound **63a** with ethyl iodide failed to produce the *N*-ethyl derivative **63c**. Only the starting material was isolated. Therefore, we used an alternative acylation-reduction procedure^[102] which gave compound **63c** in nearly quantitative yield. The final step – reductive debenzylation of the ether **63c** into phenol **42b** – was carried out successfully, and the target product was isolated in high yield (92%).

Scheme 21. Synthesis of the crown-ether building block with an additional coordination site (compound **42c**).

The last starting material in this crown ether series – the phenol **42c** – was prepared by alkylation of compound **63a** with methyl-2-bromoacetate in acetonitrile.^[64] This procedure afforded the ester **63d** which was debenzylated in MeOH to produce the required compound **42c** in very high yield (95%).

After the successful syntheses of the building blocks with azacrown-ether residues fused with the aromatic ring bearing the hydroxy group, the synthesis of phenol **68**, in which an

azacrown-ether residue is attached to the aromatic ring, was developed. This compound was necessary for the synthesis of the fluorescent dye **70** (see Scheme 24), in which the Ca chelator is directly connected to the π -system of the fluorophore.

Scheme 22. Preparation of the building block **68** with an azacrown-ether residue attached to the aromatic ring.

The precursor of phenol **68** – compound **67** – was prepared by a Buchwald-Hartwig amination of *m*-bromanisol (**64**) with aza-15-crown-5 (**66**) as described.^[103] The yield of compound **67** was found to be high (63%). The methoxy group in compound **67** could be cleaved selectively with lithium iodide in 2,4,6-collidine,^[104] and the required product **68** was isolated in moderate yield (47%).

Scheme 23. Synthesis of the benzophenone **69**.

“The second half” of the rhodoles **1a-c** – the benzophenone derivative **69** – was prepared by Friedel-Crafts acylation of resorcinol (**38-H**) with phthalic anhydride **30** in the presence of aluminum chloride as a catalyst.^[64] The main reason, why we chose the combination of compound **69** with the crown ethers **42a-c** (but did not prepare the corresponding benzophenones from phthalic anhydride and phenols **42a-c**) is that we not only reduced the total number of synthetic steps, but also saved the valuable azacrown ethers **42a-c** and **68**.

Scheme 24. Synthesis of the azacrown dyes – rhodols **1a-c** and **70**.

The rhodols with crown-ether residues were synthesized under conditions mentioned in Section 2 of Chapter 2. The starting compounds **42a-c**, **68** + **69** were heated in propionic acid in the presence of catalytic amounts of TsOH·H₂O. The yields of the final compounds **1a-c** and **70** were low, but we always isolated enough material to study the spectroscopic properties and parameters of the binding with calcium.

3.4. Spectroscopic properties of the target compounds in the presence of Ca²⁺ ions

The indicator **70** was prepared in order to check our assumption mentioned in Section 1 of Chapter 2. We assumed if we connect the crown ether with the aromatic ring in xanthene via only one heteroatom (nitrogen), such indicator will have a lower fluorescent response in the presence of calcium in the medium, than in the case of two common heteroatoms. The spectroscopic parameters of compound **70** were measured in methanolic and aqueous solutions (at pH = 7.2).

Figure 45. The absorption and fluorescence spectra of compound **70** in MeOH ($c = 1.05 \times 10^{-5}$ M): $\lambda_{abs}^{max} = 513$ nm, $\lambda_{fl}^{max} = 540$ nm.

The positions of absorption and fluorescence maxima only slightly deviate from the published values for the parent rhodol **39-H** (in methanol: $\lambda_{abs}^{max} = 517$ nm, $\lambda_{fl}^{max} = 542$ nm).^[105]

The extinction coefficient for compound **70** was 1.2 times higher than that of rhodol **39-H** (5.2×10^4 vs. 3.9×10^4). The fluorescence quantum yield for indicator **70** was also higher than that of analogue **39-H** (80% vs. 58%). Thus, the chromophore of compound **70** was found to have good spectroscopic properties.

It is not surprising, that the absorption and fluorescence spectra of rhodols are sensitive to pH. In our case, such a dependence was also observed (Figure 46).

Figure 46. The absorption (left) and fluorescence (right) spectra of compound **70** ($C = 3.3 \mu\text{M}$) at various pH values aqueous buffers: A) pH = 2 (black line), 5 (red), 7.6 (blue), 10 (green), 12 (light violet); B) pH = 2 (black line), 4 (red), 5 (blue), 6 (marine blue), 7.6 (light violet), 12 (olive green).

The observed sharp increase in the extinction coefficient of the absorption (up to 2 times) and in the fluorescence (up to 22 times) spectra upon changing of the pH value from 2 to 7.6 can be attributed to a deprotonation of the ammonium salt **70a** and conversion of the indicator into the neutral form **70b**, which has to be significantly more fluorescent than the charged form **70a**. Further basification of the medium (up to 12) causes some decrease in the intensity of the absorption and fluorescence bands which, probably, may be attributed to the formation of the colorless spirolactone **70c**.

Figure 47. The acid-base equilibria of the indicator **70** in aqueous solutions at various pH values.

One of the advantages of compound **70** is the negligible change of the intensity of the fluorescent signal in the pH range (7–8) (see Figure 48).

Figure 48. Dependence of the intensity of the absorption maximum (at 514 nm) of **70** on the pH (blue curve), and the intensity of the fluorescence maximum (at 542 nm) on the pH (black curve).

The main enhancement of the signals (absorption and fluorescence) is observed in the region from pH = 4 to pH = 7. From pH 10 to 12, a decrease in the fluorescence signal intensity was observed.

Figure 49. Changes in the absorption (left) and fluorescence (right) spectra of compound **70** (3.6 μM in an aqueous buffer solution at pH = 7.2) with $[\text{Ca}^{2+}] = 0 - 10^{-1} \text{ M}$. Curves at various concentration of $[\text{Ca}^{2+}]$ are marked in different colors: absorption (blue line – 0 M, red line – 100 mM); emission (orange line – 0 M, green line – 1 μM , purple line – 100 mM).

As we remember, in agreement with our expectations in the Section 1 of Chapter 2, the increase in calcium concentration should cause the only low increase in the intensity (less

than 50%) of the absorption and fluorescence bands. However, we did not observe any detectable changes in the spectra (Figure 49), that confirms our assumption to a greater extent.

The first of the target compounds – dye **1a** – also has the positions of the absorption and fluorescence maxima very close to the published values for the rhodol **39-H** ($\lambda_{abs}^{max} = 517$ nm, $\lambda_{fl}^{max} = 542$ nm in MeOH).^[105]

Figure 50. Absorption and fluorescence spectra of compound **1a** in MeOH: $\lambda_{abs}^{max} = 515$ nm, $\lambda_{fl}^{max} = 539$ nm.

Similar positions of the spectral maxima of compound **39-H** and compound **1a** can be attributed to a compensation of the introduction of the donor-alkoxy group into the *o*-position of the amino group and the absence of the second alkyl substituent on the nitrogen atom.

Figure 51. Comparison of the structures of rhodol **39-H** and compound **1a** (the new structural elements are marked in red, the absent ethyl group is indicated with dashed lines).

The extinction coefficient for compound **1a** was found to be similar to that for compound **39-H** (39000 vs. 38000 M⁻¹cm⁻¹). The fluorescence quantum yield for indicator **1a** was found to be higher than that for compound **39-H** (96% vs. 58%), due to the lower mobility of

substituents on the nitrogen atom. The fluorescence quantum yield for indicator **1a** was found to be higher than that for the crown rhodol **70** (96% vs. 80%), due to a higher degree of conjugative interaction between the lone electron pair on the nitrogen atom with the xanthene π -system. Thus, the chromophoric part of compound **1a** possesses good spectrophysical properties.

Figure 52. Changes in the absorption (left) and fluorescence (right) spectra of compound **1a** ($C = 15 \mu\text{M}$) at various pH values in aqueous buffer solutions: black line – pH = 1.5, violet line – pH = 5.5, blue line – pH = 6, red line – pH = 8.

The absorption spectra of aqueous solutions of compound **1a** at pH = 1.5–5 show two bands at 458 and at 485 nm. The first band can be attributed to the form **1a'** (Scheme 25) with the protonated nitrogen atom. The second band must be attributed to the form **1a''** with a protonated oxygen atom. The absorption spectrum at pH 5.5 has only one maximum at the 485 nm, which may be attributed to the form **1a''**. Two shoulders occur at 460 and 509 nm are the residual signals contributed by the forms **1a'** and form **1a[~]** (neutral). A further increase in the pH (up to pH = 6) is accompanied by the disappearance of the shoulder at 460 nm (absence of the form **1a'**). At pH = 6, the signal at 509 nm becomes the most intensive one (maximum), and the signal at 485 nm decreases and is registered only as a shoulder. In basic solution (pH = 8), the signals from the forms **1a''** (at 485 nm) and **1a'** disappear, and the signal from the form **1a[~]** increases. Probably the zwitter-ionic form **1a[~]** and the colorless spirolactone **1a^{**}** are less stable forms of compound **1a** under neutral and basic conditions.

Scheme 25. Acid-base equilibria of the indicator **Ia** in aqueous solutions.

In the fluorescence spectrum of **Ia** recorded at pH = 1.5, only one emission band at 516 nm (with a shoulder at 550 nm) is observed. The band at 516 nm is probably a superposition of the signals from two the forms **Ia'** and **Ia''**, and the shoulder at 550 nm can be attributed to the form **Ia~**. At pH = 5.5, the shoulder at 550 nm transforms into a maximum (at 538 nm), and the maximum at 516 nm become to be a shoulder. This could mean, that the ratio $[\mathbf{Ia}']/[\mathbf{Ia}'']$ in decreases solution. At pH = 6, the intensity of the shoulder (at 516 nm) decreases considerably, while the intensity of the maximum (at 538 nm) decreases only slightly. In basic solution (at pH = 8) the intensity of the band at 538 nm becomes slightly lower, while the shoulder at 516 nm disappears.

Figure 53. Absorption of a solution of **Ia** at 510 nm (filled symbols, left axis) and at 460 nm (hollow symbols, right axis) plotted as a function of the pH value.

The same feature as for compound **70** – the negligible change of absorption upon variation of the pH value in the range between 7 and 8 – was found for compound **1a**. It is obvious, if we represent the data on the absorption as given in Figure 53. The main enhancement of the signal (absorption) is registered in the pH range from 4 to 7. The changes in absorption in the interval of pH 7–8 are negligible for the band at 460 nm, while the intensity of the band at 510 nm increases by increasing the basicity of the solution.

Figure 54. Changes in the absorption (left) and fluorescence (right) spectra of compound **1a** ($C = 7.5 \mu\text{M}$) in aqueous buffer solutions ($\text{pH} = 1.5, 8.0$) with free $[\text{Ca}^{2+}]$ ranging from 0 to 10^{-1} M. Lines of various colors correspond to various Ca-concentration: **pH = 1.5**: absorption and emission (ochre line – 0 M, blue line – 100 mM); **pH = 8.0**: absorption and emission: the set of color lines represents negligible changes of the spectra in the range of calcium concentrations from 0 M to 100 mM.

Variation of the calcium concentration in the interval from 0 to 0.1 M by one-order of magnitude steps ($0, 10^{-6}, 10^{-5}, 10^{-4}$ etc.) in slightly alkaline solutions did not show any significant changes in the absorption and fluorescence spectra of compound **1a** (absorption band at 510 nm in the left and fluorescence band at 538 nm in the right picture). Another result was obtained at a low pH value (1.5): we observed some decrease in the intensity of the absorption (486 nm) and fluorescence (515 nm) bands upon increasing $[\text{Ca}^{2+}]$ values. Thus, we cannot recommend to use compound **1a** as a calcium sensor, because the effects were observed only at $\text{pH} = 1.5$ (which is far from physiological values). To explain the low effect, it is necessary to analyze the spatial structure of compound **1a**. In the initial state, the hydrogen atom of the NH group is most probably located in the crown ether cavity and forms an H-bond with the oxygen atoms. In order to bind a calcium cation, the crown-ether ring needs to be transformed in such a way that the lone electron pair of nitrogen is directed into

the cavity, and the hydrogen atom turns to be outside the cavity.^[88] Probably, this process is unfavorable for compound **Ia**, and it does not coordinate the calcium cation at all.

The main feature, which influences the spectroscopic properties of the next indicator **Ib**, is the presence of an additional ethyl group on the nitrogen atom. As a result, this donor group shifts the positions of the absorption and the emission maxima of compound **Ib** to the red (by 17–19 nm), in comparison with the corresponding values for compound **Ia** ($\lambda_{abs}^{max} = 515$ nm, $\lambda_{fl}^{max} = 539$ nm for **Ia** vs. $\lambda_{abs}^{max} = 542$ nm, $\lambda_{fl}^{max} = 558$ nm for **Ib**).

Figure 55. Absorption and fluorescence spectra of compound **Ib** in MeOH: $\lambda_{abs}^{max} = 542$ nm ($\epsilon = 22300 \text{ M}^{-1}\text{cm}^{-1}$), $\lambda_{fl}^{max} = 558$ nm.

The second consequence is a decrease of the extinction coefficient for compound **Ib** up to 2 times in comparison with the same parameter for compound **Ia**. Another structural feature which results due to the additional ethyl group is a rotation of the dialkylamino group out of its coplanarity with the xanthene aromatic system. A direct consequence of the absence of coplanarity is a decrease in the conjugation between the nitrogen lone pair and the aromatic π -system, and a decrease in the fluorescence quantum yield to 16 %.

Figure 56. Changes in absorption (left) and fluorescence (right) spectra of compound **Ib** ($C = 17 \mu\text{M}$) at various pH values of the aqueous buffer solutions; black line: pH = 1, pink line: pH = 5, violet line: pH = 13.

The absorption spectra of aqueous solutions of compound **Ib** in the range of pH from 1 to 5 (in acidic medium) contain two bands at 488 nm and at 517 nm. The first band, fluorescein-like, could be attributed to the form **Ib'** (Scheme 26) with a protonated nitrogen atom. The second band could be attributed to the form **Ib''** with a protonated oxygen atom. At pH > 5, there is only one band at 531 nm, which we attribute to the neutral form **Ib[~]** (and/or deprotonated form **Ib***). In the fluorescence spectra in the whole pH range only one emission band was observed. Its maximum shifted from 514 nm (at pH = 1) to 554 nm (pH = 5), and then to 560 nm (pH = 13).

The observed increase in absorbance (up to 3 times) and in the fluorescence intensity (up to 5 times) upon changes of the pH from 1 to 8 can be explained with the deprotonation of the ammonium salts **Ib'** and **Ib''** and the conversion of the indicator to the neutral form **Ib[~]**, which is significantly more fluorescent than the cations **Ib'** and **Ib''**. Further basification of the solution (up to pH = 13) does not decrease the intensity of the absorption and fluorescence. Unlike in the case of compound **70**, the colorless spirolactone (**Ib****) is not formed in the basic medium.

Scheme 26. Protonated and deprotonated forms of the indicator **Ib** in aqueous solutions at various pH values.

The same feature as for compound **Ia** – a negligible change of the fluorescence and absorption signal at pH = 7–8 was also observed for compound **Ib**. This is demonstrated clearly by the representation the data in Figure 57.

Figure 57. Absorption and emission intensities of the solutions of the compound **Ib** at various pH values. **Left picture:** absorption at 530 nm (filled symbols, left axis) and at 488 nm (hollow symbols, right axis) at pH = 1–13; **right picture:** emission at 560 nm (filled symbols, left axis) and at 514 nm (hollow symbols, right axis) at pH = 1–13.

The main changes of the signal intensities (absorption and fluorescence) were observed at pH = 3–7; changes at pH 0–3 and 7–14 were insignificant.

Figure 58. Changes in the absorption (left) and fluorescence (right) spectra of compound **Ib** ($C = 18 \mu\text{M}$) in aqueous buffer solutions ($\text{pH} = 7.2$) with free $[\text{Ca}^{2+}] = 0\text{--}0.1 \text{ M}$; the different concentration of $[\text{Ca}^{2+}]$ are marked in different colors: absorption and emission (black line – 0 M , dashed lines – intermediate concentrations, red line – 100 mM , blue line – after the addition of EDTA to a final concentration of 27 mM). The arrows indicate the changes observed with increasing concentrations of Ca^{2+} and EDTA.

In the absorption spectrum of the initial solution of compound **Ib** (without calcium), two bands were observed at 484 and 512 nm which may be attributed to the species **Ib**[~] and **Ib**^{~~} mentioned above. Only the first of these forms can interact with Ca^{2+} (due to the absence of the positively charged nitrogen atom).

Scheme 27. Complexation of the calcium cation by indicator **Ib**.

An increase in the calcium ion concentration from 1 to 126 mM resulted in a red shift of the absorption band (from 512 to 526 nm), and simultaneously, an increase in the absorption intensity was observed (up to 40% at $[\text{Ca}^{2+}] = 126 \text{ mM}$). These changes of the calcium concentration increased the intensity of the fluorescence band: it became 3 times more intensive at $[\text{Ca}^{2+}] = 126 \text{ mM}$. However, the red shift of the fluorescence maximum (which was also observed) was found to be only 4 nm (from 558 nm in the absence of calcium to 562 nm at $[\text{Ca}^{2+}] = 126 \text{ mM}$). Such kind of atypical influence of calcium on absorption and fluorescence spectra of an indicator with the xanthene fluorophore (red shift) may be

attributed to the fact that the calcium cation does not only coordinate to the nitrogen atom, but also to the oxygen atom attached to the aromatic ring.

14c: FluoRhod-2: $R^1 = \text{CH}_2\text{CH}_2\text{COOH}$, $R^2 = Y = \text{CH}_3$, $X = \text{H}$;

Figure 59. Comparison of the two calcium indicators with a rhodol fluorophore.

As was discussed in Chapter 1, the compound **14c** with a rhodol fluorophore displayed a blue shift of the absorption and fluorescence maxima upon coordination with calcium (or protonation). The indicator **Ib** also displayed a blue spectral shift upon protonation. However, protons coordinate first with the nitrogen atoms. In the case of indicator **Ib**, the calcium cation does not only bind to the nitrogen, but also to an adjacent oxygen atom. In the case of an octadentate ligand as in the indicator **14c**, the calcium cation is kept only by six heteroatoms. Therefore, it does not need to bind to the oxygen atom attached to the rhodol system.

As far as the quantitative parameters of compound **Ib** are concerned, they can best be evaluated, when the data are presented as in the Figure 60.

Figure 60. Dependence of the fluorescence parameters on the calcium concentration. Left

plot: left vertical axis $\frac{I_x^{\text{fl}} - I_{\text{free}}^{\text{fl}}}{I_{\text{sat}}^{\text{fl}} - I_x^{\text{fl}}}$ (for the 1 : 1 complex of **Ib** with Ca^{2+} ; hollow circles), right

vertical axis $\frac{(I_x^{fl} - I_{free}^{fl}) * (I_{sat}^{fl} - I_{free}^{fl})}{(I_{sat}^{fl} - I_x^{fl})^2} * \frac{1}{2C_{ind}}$ (for the 2 : 1 complex of **Ib** with Ca^{2+} ; filled circles). C_{ind} stands for the whole indicator concentration in solution; for other abbreviations, see Section 2.1. The right plot represents the same parameters in the range of $[Ca^{2+}] = 0.000$ – 0.042 M.

As was mentioned in Section 2.1, the calcium concentration from the fluorimetric data can be calculated according to the equation (3):

$$[Ca^{2+}] = K_D \left(\frac{I_x^{fl} - I_{free}^{fl}}{I_{sat}^{fl} - I_x^{fl}} \right) \quad (3)$$

The unknown parameter K_D may be easily calculated from the plot $\frac{I_x^{fl} - I_{free}^{fl}}{I_{sat}^{fl} - I_x^{fl}}$ vs. $[Ca^{2+}]$.

The tangent of this curve is equal to K_D^{-1} , if the dependence is linear. In our case, the resulting curve (hollow circles) is not linear; the most probable explanation is a false binding model. The equation (3) is valid for a 1 : 1 complex of the indicator with calcium. On the basis of the structure of compound **Ib**, we can assume the formation of a sandwich-like complex with two molecules of the indicator and one calcium ion. For this model, another equation for the calcium concentration (and dissociation constant) is obtained:

$$[Ca^{2+}] = K_D \frac{(I_x^{fl} - I_{free}^{fl}) * (I_{sat}^{fl} - I_{free}^{fl})}{(I_{sat}^{fl} - I_x^{fl})^2} * \frac{1}{2C_{ind}} \quad (5)$$

However, even with this case a linear dependence of $\frac{(I_x^{fl} - I_{free}^{fl}) * (I_{sat}^{fl} - I_{free}^{fl})}{(I_{sat}^{fl} - I_x^{fl})^2} * \frac{1}{2C_{ind}}$ vs.

$[Ca^{2+}]$ was not observed, and therefore, the dissociation constant for the complex of compound **Ib** and calcium cannot be calculated. The absence of a linear dependence for both models (1:1 and 2:1 complexes) may be explained, for example, by the presence of both complexes in an equilibrium (Scheme 28). In this case, however, we cannot evaluate any quantitative parameters, because we cannot extract the coefficient “c” in the dependence $I_{fl} = c * [IM]$ from the fluorescence measurements.

Scheme 28. The equilibrium in the system indicator – metal ion, in which I stands for indicator molecule, M for metal ion.

Thus, we cannot calculate the equilibrium constants for complexes IM and I₂M, and this complicates the comparison of the binding properties of compound **Ib** with those of the other known indicators. Moreover, the inavailability of the binding constants makes the calculation of the calcium concentrations difficult. However, we can conclude that for compound **Ib** the “working interval” of calcium concentrations is from 5 to 126 mM.

The change of the donor ethyl group in compound **Ib** to a carboxymethyl residue results in the compound **Ic** with nearly the same positions of the absorption and emission maxima, as for the unsubstituted indicator **Ia**.

Figure 61. Absorption and fluorescence spectra of compound **Ic** in methanol: $\lambda_{abs}^{max} = 517$ nm ($\epsilon = 30300 \text{ M}^{-1}\text{cm}^{-1}$), $\lambda_{fl}^{max} = 541$ nm.

The extinction coefficient of compound **Ic** is slightly lower than that of compound **Ia** (30300 vs. $39000 \text{ M}^{-1}\text{cm}^{-1}$); at the same time, the ϵ -value for **Ic** is 1.5 times higher than that of compound **Ib**. As a result of the introduction of the carboxymethyl group, the coplanarity of the dialkylamino group with the xanthene aromatic system may be distorted as in the case of compound **Ib**). However, for the compound **Ic**, the fluorescence quantum yield was found to be high (72 % vs. 16% for compound **Ib**).

Figure 62. Left: absorption spectra of compound **1c** (C = 5.7 μM) at various pH values in aqueous buffer solutions: black line: pH = 1, green line: pH = 5, red line: pH = 5.5, purple line: pH = 6, blue line: pH = 8. Right: absorption of aqueous solutions of compound **1c** at 508 nm (filled circles, left axis) and at 460 nm (filled rhombs, right axis) plotted as a function of the pH; the absorption (at 508 nm) of aqueous solutions of compound **1c** with calcium additions (hollow circles, left axis) plotted as a function of pH.

The absorption spectra of the aqueous solutions of compound **1c** in the pH range from 1 to 5 shows two bands at 457 and at 483 nm. The first one is assigned to the form **1c'** (Scheme 29) with a protonated nitrogen atom. The second band is assigned to the form **1c''** with a protonated oxygen atom. At pH 5.5, there is only one maximum (at 483 nm) with two shoulders. The left shoulder, at 460 nm, corresponds to the residual form **1c'** (+ signal from the zwitter-ionic form **1c^z**), and the second shoulder (at 509 nm) corresponds to the neutral form **1cⁿ**. A further increase in the pH (up to pH = 6) decreases the intensity of the shoulder at 460 nm, so that the signal of the form **1c'** disappears, but the signal of the zwitter-ionic form **1c^z** still remains.

Scheme 29. Various protonated forms of the indicator **Ic** in aqueous solutions at different pH values.

At pH = 6, the intensity of the band at 509 nm increases, and the band at 485 nm transforms into a shoulder. In a basic medium (pH = 8), the absorption maximum attributed to the form **Ic**[~] (at 460 nm) disappears, and the intensity of the absorption of the form **Ic**[~] increases, owing to an increase of the fraction of compound **Ic** in the form **Ic**[~] and a conversion also of compound **Ic** into the form **Ic**^{*} (which has the same position of its absorption maximum at 509 nm). In this instance, the form **Ic**^{''} is absent, and it probably is replaced by the form **Ic**^{**} (which presumably has the same position of its absorption maximum at 483 nm), because this zwitter-ionic form could be formed from **Ic**^{''} by deprotonation of a carboxy group. At pH = 8, the form **Ic**^{**} is represented in the absorption spectrum by a shoulder at 483 nm.

As far as the independence of the spectroscopic signal from the pH value at pH = 7–8 is concerned, the wavelength of 508 nm seems to be preferable for practical applications, because there are smaller changes in absorption in this interval of pH, compared to those at 460 nm (see right plot in Figure 62).

Figure 63. Small changes in the absorption (left) and fluorescence (right) spectra of compound **Ic** (3.6 μM in an aqueous buffer solution at $\text{pH} = 7.2$) with free $[\text{Ca}^{2+}]$ values ranging from 0 to 0.1 M; curves corresponding to various concentrations of Ca^{2+} are drawn in different colors: absorption and emission (black line – pure indicator, red line – pure indicator + 10 equiv. of EDTA, blue line – pure indicator + 10 equiv. of EDTA + 10 equiv. of Ca^{2+} , green line – 100 mM of Ca^{2+}).

Since in the preliminary measurements the sensitivity of compound **Ic** to calcium ion concentrations no significant changes (data not shown) were observed then we decided to use EDTA to remove the possible reason of the absence of spectroscopic signals. Up to 10 equivalents of EDTA were added to bind the possible cations, which could be located in the cavity surrounded by the crown-ether ring and the carboxy group. Therefore, in order to provide a starting point for the measurements, we bound the excessive EDTA by the addition of 10 equivalents of calcium chloride (CaCl_2). Then we performed the main measurements. Unfortunately, this indicator displayed only a very small decrease in its absorption and small increase in its fluorescence spectra with very high calcium ion concentrations (100 mM). Such response is too weak, to apply compound **Ic** as calcium indicator.

4. Synthesis of *N, N, N', N'*-tetramethylrhodamine (TMR) derivatives with an azacrown-ether ring fused with the 9-(2-carboxy)phenyl ring

All other target structures **IIa-b** represent derivatives of TMR. For their preparation, we had to condense 3-(*N,N*-dimethylamino)phenol (**71**) with a phthalic anhydride bearing a fused azacrown system (compound **72a**) or a phthalic anhydride with two different substituents in positions 4 and 5, from which the azacrown ether would later be constructed (e. g. compound **74** in Scheme 31).

Scheme 30. Building blocks **71** and **72a** from which the target fluorescent sensors **IIa-b** may be prepared.

The latter possibility appeared to be simpler and easier, and therefore, we embarked on the synthesis of the TMR derivate **73a** (Scheme 31).

4.1. Synthesis via the initial formation of TMR derivatives

The TMR derivative with a nitro and a methoxy group in the phenyl ring (compound **73a** in Scheme 31) was chosen as a precursor for the required substances **IIa-b**.

Scheme 31. Rhodamine **73a** and building blocks (**71** and **74**).

The known synthesis of 4-methoxy-5-nitrophthalic anhydride (**74**) starts from 1,2-dimethyl-4,5-dinitrobenzene (**77**).^[106] This symmetrical dinitro compound **77** was prepared in 50% overall yield by sequential oxidation of the commercially available 4,5-dimethyl-2-nitroaniline (**75**) with $\text{K}_2\text{S}_2\text{O}_8/\text{H}_2\text{SO}_4$ (to the corresponding nitroso compound **76**) and subsequently with fuming nitric acid.^[107] Conversion of the *o*-xylene derivative **77** into the corresponding phthalic acid **78** was achieved (though in low yield) by prolonged heating in a sealed tube with 25% aq. HNO_3 at 180 °C.

Scheme 32. Preparation of compound **78** as a precursor for 4-methoxy-5-nitrophthalic anhydride **74**.^[106,107]

The authors of the original report^[106] managed to achieve higher yields (up to 63%) by repeating the oxidation of the isolated unreacted compound **77**. The entire procedure could not be scaled-up, because of the high risk of an explosion. Therefore, we tried to find a more productive and safe route to compound **74**.

Oxidation of compound **77** with basic aq. KMnO_4 did not provide the dicarboxylic acid **78**.^[106]

Scheme 33. An attempted alternative approach to 4-methoxy-5-nitrophthalic acid **79**.^[108,109]

A possible alternative approach to the dicarboxylic acid **79**^[109] is presented in Scheme 33. Nitration of 4-methoxyphthalic acid (**81**)^[108] provided the required compound **79** in a very low yield of 5.4%. Another regioisomer, isolated from the reaction mixture, turned out to be compound **82** (Scheme 33). It is interesting that the more sterically congested compound **82** was formed in higher yield (14%) than the less sterically crowded substance.

One more idea, how to produce the acid **79**, was based on the following observations. If it is not possible to oxidize compound **77** to the corresponding phthalic acid with KMnO_4 , but it is possible to oxidize of 3,4-dimethylphenyl methyl ether **80** to 4-methoxyphthalic acid **81**, then it may be possible to oxidize 4,5-dimethyl-2-nitrophenyl methyl ether **83** to the acid **79**.

Scheme 34. An easy way to 4-methoxy-5-nitrophthalic anhydride **74** from 4,5-dinitro-1,2-dimethylbenzene (**77**).

Eventually, we synthesized the phthalic anhydride **74** in a very efficient way (see Scheme 34). Aromatic nucleophilic substitution of the nitro group in compound **77** with MeONa afforded compound **83** in high yield. Oxidation of the methyl groups in **83** with basic aq. KMnO₄^[108] led to the phthalic acid **79**, which cyclized by heating in acetyl chloride^[106] and to produce the anhydride **74**. It was necessary to optimize the conditions of the first step, in order to achieve the highest possible yield of compound **83** and to avoid the formation of side products (e. g. substituted diphenylmethanes arising from an S_NAr-reaction between the deprotonated methyl group which may react with the starting compound **77**, substituting one of the nitro groups).

Scheme 35. Synthetic route to the TMR derivatives **73a-b**.

The first approach to the TMR derivatives **73a,b** included heating a mixture of the substituted phthalic anhydride **74** and aminophenol **71** in toluene.^[110] However, the yield of the target products **73a,b** was very low (9%). The second attempt was to use conditions as applied for the rhodol synthesis. The yield of the TMR derivatives **73a,b** was increased to 18%, but remained low. On for of that, the isomers **73a** and **73b** could not be separated. Therefore, this approach was not pursued any further.

4.2. Elaboration of a route to phthalic acid derivatives with an azacrown-ether fused to the aromatic ring

Fusion of the azacrown ether with the positions 4 and 5 of the aromatic ring in phthalic anhydride (compounds **84a,b**) would provide an easy route to the required fluorescent sensors **IIa,b** (Scheme 36).

Scheme 36. A retrosynthetic consideration of an alternative approach to compounds **IIa-c** based on the phthalic anhydrides **84a,b**.

In order to fuse the azacrown-ether system with the aromatic ring in phthalic anhydride, it was necessary to use its protected form (or a synthetic equivalent), because the multistep procedures for the introduction and cyclization of an azacrown ring involve various highly reactive substances. Methyl groups appeared to be a bad choice, because they require oxidation in the final step, in the presence of the electron-donating azacrown-ether ring, which makes the aromatic nucleus very susceptible to oxidation. Therefore, we chose another synthetic equivalent of the phthalic anhydride, its *N*-methyl imide **90**, which is depicted in Scheme 37.

Scheme 37. Synthesis of the aminophenol **90** as a key intermediate.

To access compound **90**, commercially available 4,5-dichlorophthalic acid (**85**) was transformed into its anhydride **86**,^[111] and the latter then to the *N*-methyl imide **87**.^[112] A twofold nucleophilic substitution of the two chlorine atoms in **87** was performed with KNO₂ in DMF at ca. 150 °C to give the *ortho*-hydroxynitro derivative **88**. The formation of the latter may be explained, if we assume that one chlorine atom is replaced with a nitro group, and another one with an O=N–O[−] group (KNO₂ acts as an ambident nucleophile). The nitrite ester group is then hydrolyzed upon aqueous work-up.^[111] Catalytic reduction of the potassium salt **89**^[113] gave 4-amino-5-hydroxy-*N*-methylphthalimide (**90**).

Scheme 38. Synthetic approaches to azacrown-*N*-methylphthalimide **92**.

With the required building block **90** at hand, we studied the conditions, under which the azacrown ring can be build-up using the hydroxy and amino groups in the *o*-position to each other (Scheme 38). For that, it was necessary to use the diiodide **91** prepared from tetraethylene glycol dichloride (**50**),^[114a] because ditosylate **44** failed to provide the required macrocycle **92**. Even with the diiodide **91** the highest achieved yield was only 14%. Therefore, we turned to a step-wise construction of the azacrown ring using tetraethylene glycol derivatives **54-Ac** and **54-Z**^[114b] (Scheme 39).

Employment of the alkylating agent of compound **54-Z** instead of **54-Ac** did not improve the yield of the intermediate **93-H** (see Scheme 39).

The trityl group was chosen as a new protection for the tetraethylene glycol derivatives (**54-Tr**, **95**, **96**) with good leaving groups (Cl, Ms and I) (Scheme 40). The yield of the chloride **54-Tr** was low (35%).^[115] In the synthesis of compounds **95** and **96**, the protecting group was introduced in the first step, by the reaction of compound **52** with chlorotriphenylmethane, which gave the ether **94** in high yield (99%).^[116] The remaining free hydroxy group in the ether **94** was converted into mesylate to give compound **95** in 91% yield,^[116] from the latter, the iodide **96** was prepared in 88% yield.^[117]

Scheme 41. Optimization of the conditions in the preparation of the alcohol **93-H**.

In the first experiments, the mesylate **95** was used as an alkylating reagent. The overall yield of the alkylation products (**93-Tr** and **93-H**) was higher than in the reaction of the salt **89** with the chloride **54-Z** (44% vs. 34%). However, more by-products were detected, and a mixture of compounds was formed (**93-Tr** and **93-H**). In order to increase the yield of the target product **93-Tr**, another alkylating agent, the iodide **96**, was used. To suppress the deprotection of the hydroxy group, the reaction temperature was decreased to 70 °C, and a longer reaction time was applied (5 instead of 2 days). The highest conversion of the potassium salt **89** into the ether **93-Tr** was found to be 59%; the content of the non-reacted starting material was 25%. In order to prove our assumption that the decomposition of iodide **96** was quicker than its reaction with the potassium-salt **89**, the mode of the iodide addition was changed. Half an equivalent of compound **96** was added in four portions (in the beginning and every 12 h) to the reaction mixture. However, the conversion was found to be the same (59% of **93-Tr** and 26% of **89**). Also, a change of the solvent to HMPTA in this reaction did not help to shift the equilibrium towards the target product **93-Tr**. Unfortunately, the ratio became even worse, i. e. 49:37.

For the deprotection of the nitroether **93-Tr**, two procedures were applied. Heating the starting material in glacial acetic acid^[118] afforded the target product **93-H** only in moderate yield (40%). The main by-product in this reaction was the ester **93-Ac**. Treatment of the ether

93-Tr with a 2 M methanolic solution of $\text{BF}_3 \cdot \text{Et}_2\text{O}^{[119]}$ gave the pure alcohol **93-H** in 98% yield.

Scheme 42. Synthesis of the *N*-tosylated azacrown ether **99** by a ring-closing reaction sequence.

After that the nitro group in the alcohol **93-H** was catalytically reduced, and compound **97** was converted into the bis-tosylate **98** (Scheme 42). Conventional conditions (Cs_2CO_3 , DMF, 90 °C) were used for the ring-closing reaction; unfortunately, the yield of the monotosylate **99** was low (even after the reaction time was increased from 24 to 39 h).

Scheme 43. Attempted *N*-detosylation of the crown ether **99**.

Unfortunately, all approaches to recover the target crown ether **92** from its tosylamide **99** failed. Under mild detosylation conditions ($\text{HF} \cdot \text{Py}^{[120]}$ or $\text{TMSI}^{[121]}$), only the starting compound **99** was isolated; and with sodium naphthalenide, the reaction mixture did neither contain the starting material **99**, nor the target crown ether **92**.

In order to be able to efficiently detosylate of compound **99** we were forced to modify the synthesis and circumvent the detosylation step. Towards that, it was necessary to prepare the monotosylate **100**. This compound could be produced not only by a selective tosylation of the amino alcohol **97**, but also by tosylation of the nitro alcohol **93-H** followed by reduction.

Towards that, the nitrotosylate **101** was obtained from the nitroalcohol **93-H** in 53% yield according to the standard procedure. Then the nitro compound **101** was quantitatively converted into the amine **100** by catalytic hydrogenation. The iodide **102** was also produced by nucleophilic substitution of the tosyl group in compound **100** with iodide anion.

Initially, two bases (DBU and Cs₂CO₃) were tried in order to perform the cyclization to the crown ether **92**. In both cases, the target product **92** was observed, and in the case of DBU,

this product was isolated. However, in these experiments the yield of the crown ether **92** was inacceptably low (maximum 12%).

Scheme 46. Successful cyclization of the iodide **102** to the crown ether **92** and the synthesis of the ethylated derivative **92-Et**.

To improve the yield of the target product **92**, the tosyl leaving group was changed to an iodide (Scheme 46), in addition, sodium iodide was used as a templating agent, and a softer base (DIPEA) was applied. As a result, the yield of compound **92** increased to 42%. Then the ethyl group was introduced into the crown ether **92** by heating it with diethyl sulfate at 140 °C for 1 h.^[122]

Chapter 3. Synthesis of SplAsH-based fluorescent labels for tetracysteine tags and their bioimaging tests

1. Development of biarsenical probes

The first biarsenical probe – compound **103a** – was described in 1998 by R. Tsien et al.^[3] It was based on fluorescein with two dithiarsolanic rings attached to positions 4 and 5 (see Table 5). Due to the reversibility of the reaction of As(III) with thiols, ethanedithiol ligands can be replaced with other thiols (e. g. cysteine residues in proteins).

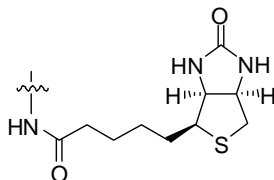

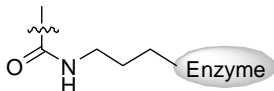

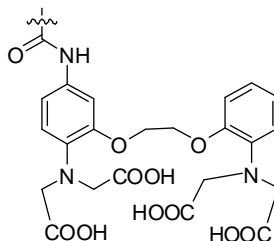

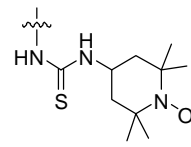

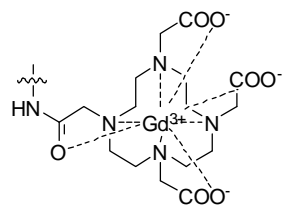

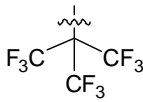

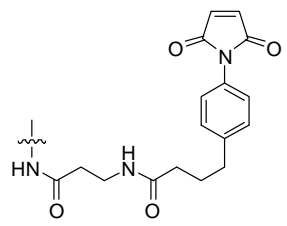

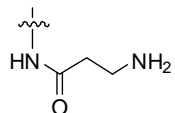

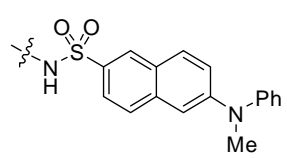

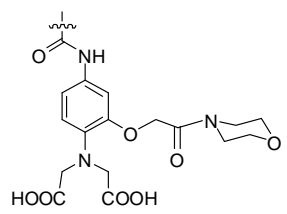

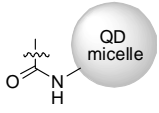

Table 5. FAsH and its derivatives.^[3, 123-133]

To provide a high selectivity of any new probe, a special peptide sequence with four cysteine residues was developed.^[123] This genetically encodable domain, the so-called “tetracysteine motif”, may be represented as follows: CCXYCC, in which X, Y stands for any amino acid residue and C for cysteine. Owing to the required positions of the cysteine residues in the amino acid sequence, a highly stable complex ($K_D \approx 10^{-11}$) between two arsenic atoms and two pairs of cysteine residues is formed. The most stable complex was produced, with X = P (proline) and Y = G (glycine). Such kind of insertion (PG) between the two pairs of cysteines provides the required mutual orientation of the two pairs of thiol groups. Each pair of thiol group binds with one of the two arsenic atoms in compound **103a**.

Scheme 47. Conjugation of FlAsH (compound **103a**) with the CCPGCC peptide.

Besides its perfect binding ability, compound **103a** undergoes an interesting transformation of properties. A solution of **FlAsH** in a buffer, which absorbs light in the region similar to fluorescein (λ_{\max} (**103a**) = 508 nm), is almost non-fluorescent, due to the

vibrational deactivation of the excited state of the FIAsh molecules. However, addition of the peptide or protein, with a CCPGCC amino acid sequence to this solution, makes it highly fluorescent, owing to the progress of the binding reaction (Scheme 47). Therefore, compound **103a** can work not only as a selective binding unit, but also as a fluorescence label for any biomolecules with the “tetracysteine motif”.

Owing to the intense fluorescence of the adducts (Scheme 47), and high affinity of compound **103a** to tetracysteine-containing fragments, this substance and its analogues have found many applications in biological research, e. g., in the cell imaging,^[3, 123] protein dynamics,^[123a] protein purification,^[124] applications of the FRET method (fluorescence resonance energy transfer).^[125]

FIAsh derivatives are used to deliver different labels to the target protein. Typical examples of such labels are: calcium chelators for the fixation of calcium nanodomains in cells (compounds **103e**,^[123b] **103q**^[126]), spin labels for studying of protein interactions by EPR (compound **103f**^[123b]), radioactive labels for the evaluation of protein traffic (compound **103g**^[123b]), iodo and bromo derivatives for the heavy atoms X-ray scattering research (compound **103h**^[123b]), labels with paramagnetic ions for ¹H-NMR spectroscopy (e. g. compound **103i**^[123b]), ¹⁹F-NMR probes (compound **103j**^[123b]), labels that consist of quantum dot micelles with persistent fluorescence (compound **103r**^[127]).

FIAsh derivatives may be used as bifunctional linkers. For example, it is possible to bind the target peptide or protein (decorated with the “tetracysteine motif”) to: streptavidine (via biotinylated compound **103b**^[123b]) or its derivatives (with the help of compound **103s**^[128]), the enzymes via a lysine residue (using compound **103c**^[123b]), monothiol-modified nucleic acids (with compound **103k**^[129]), NHS-functionalized agarose gel (used for protein purification by means of affinity chromatography [with the help of compound **103l**^[124]]). The FIAsh dimer with two xanthene nuclei and four arsenics (compound **103t**^[123]) can induce the homodimerisation of peptides and proteins, which contain two tetracysteine tags.

Some of the FIAsh labels (compound **103d**^[123]) may be applied for staining objects, which may be indirectly visualized, i. e. by electron microscopy using the photooxidation of diaminobenzidine followed by staining with osmium salts. The dye **103d** converts oxygen from the triplet into the singlet state, and the highly reactive singlet oxygen is capable of polymerizing diaminobenzidine into a densely localized precipitate. The latter could be stained with osmium tetroxide which can be detected by electron microscopy.

The compound Mansyl-FIAsh (**103m**) was produced in 2004.^[130] It was found to be an indicator of protein conformations. This substance was attached to calmoduline protein

decorated with a tetracysteine tag. Changes in fluorescence of the Mansyl-FlAsH label were observed upon conformational changes of calmoduline, the behaviour of which could be regulated by the calcium cation fluxes.

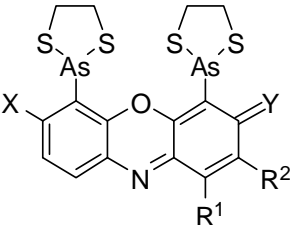

It should be noted, that most applications of FlAsH derivatives utilize only the selective binding of this probe to the tetracysteine motif, but not their fluorescent properties. FlAsH derivatives as fluorescent labels have some disadvantages: 1) a limited photostability and pH sensitivity of fluorescein in the physiological pH range;^[131] 2) a high fluorescence background (at ca. 500 nm) in the cell staining experiments.^[132] The first drawback was overcome by the introduction of the fluorine atoms into the FlAsH structure (compounds **103n** and **103o**).^[131] Compound **103n** was 50 times more photostable than the parent biarsenical probe (**103a**). Both fluorinated derivatives absorb light of ca. 500 nm two times stronger than compound **103a**. Their fluorescence quantum yields are two times higher, and their pH sensitivity is lower. The introduction of fluorine atoms into the xanthene system of **FlAsH** resulted in a blue shift of the absorption and fluorescence maxima for complexes of the biarsenical probe with the dodecapeptide with 4 cysteine residues ($\lambda_{abs}^{max} = 511$ nm, $\lambda_{fl}^{max} = 527$ nm for FlAsH-dodecapeptide; $\lambda_{abs}^{max} = 500$ nm, $\lambda_{fl}^{max} = 522$ nm for F2FlAsH-dodecapeptide). However, introduction of fluorine atoms into the benzene ring attached to the xanthene system produced the opposite effect ($\lambda_{abs}^{max} = 528$ nm, $\lambda_{fl}^{max} = 544$ nm for F4FlAsH-dodecapeptide).

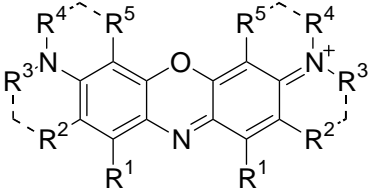

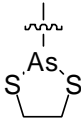

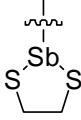

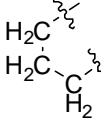

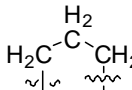

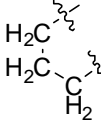

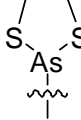

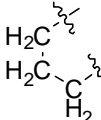

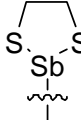

A new improved biarsenical probe was obtained by the introduction of an additional carboxy group into the benzene ring of **FlAsH**.^[133] This probe is called CrAsH (compound **103p**). Owing to the higher hydrophilicity of the new probe, the background fluorescence signal (the result of the non-specific binding of **FlAsH** with proteins) was reduced 8–9 times. The relative enhancement of the fluorescence upon complex formation was the same as in the case of **FlAsH** (35 times). The absorption and fluorescence maxima of compound **103p** were only slightly red-shifted in comparison with the FlAsH-peptide complex ($\lambda_{abs}^{max} = 513$ nm, $\lambda_{fl}^{max} = 534$ nm vs. $\lambda_{abs}^{max} = 511$ nm, $\lambda_{fl}^{max} = 527$ nm). As well as for compounds **103n** and **103o**, the lower pH sensitivity of compound **103p** was observed (in the physiological pH range).

The "green" emission is not optimal for the use of **FlAsH** as a fluorescent label in biological research; typical limitations associated with this spectral region are: cellular absorbance of light, light scattering and cellular autofluorescence. The introduction of four electron-withdrawing groups into the benzene ring of **FlAsH** (in compound **103o**) shifted the absorption and fluorescence maxima to the red only slightly. Therefore, another approach, i. e. the radical change of the fluorophore, was pursued. The phenoxazine compound **104**

(without substituents) was chosen as a fluorescent core for the red-emitting biarsenical probe. Besides the required absorption and emission bands, the phenoxazine system provides a suitable position for the attachment of the dithiarsolanic rings.

Table 6. Phenoxazine-based biarsenical probes.^[123a, 134-136]

| 104d |  |  | |  | |
| 104e | H |  | | H |  |
| 104f | H |  | | H |  |

Compound **104a** was the first example in this series. It represents an environmentally-sensitive fluorescent probe for imaging conformational changes in proteins of living cells.^[134] The reported changes of the fluorescence signal of this probe are caused by conformational changes of the recombinant calmodulin, which are regulated by the calcium concentration in the medium. The fluorescence maximum of compound **104a** is found in the region from 560 to 610 nm (depending on the solvent polarity).

The simpler phenoxazine derivative ReAsH was introduced by Adams et al.^[123a] The absorption and fluorescence maxima of this biarsenical probe were significantly red-shifted in comparison with the FAsH derivatives ($\lambda_{abs}^{max} = 593$ nm, $\lambda_{fl}^{max} = 608$ nm). Surprisingly, compound **104b** which does not include heavy atoms, has shown a good photoconversion of triplet oxygen into singlet oxygen (revealed in the course of staining of the cellular objects with a polymer of diaminobenzidine and then with osmium in the process mentioned above). Compound **104b** was used as a selective fluorescent label for the differentiation of "younger" and "older" proteins in the study of connexin trafficking.^[135]

Figure 65. Biarsenical probe, based on Rhodamine B.

In order to shift the spectroscopic bands of phenoxazine biarsenical probes further into the red region, dialkylamino groups were introduced into the positions X and Y of compound **104a** (see Table 6).

Interestingly, in the case of a biarsenical probe based on Rhodamine B, no changes in the fluorescence upon the formation of the complex of the model tetracysteine-containing peptide

with the rhodamine-based biarsenical probe was reported.^[123a] The main reason for that was the absence of quenching of the fluorescence in the initial state of the biarsenical probe (before the formation of the complex with the tetracysteine tag). The steric repulsions between the dithiarsolanic rings and the dialkylamino groups (see Figure 65) are responsible for that. In order to exclude these unfavorable interactions in the near IR (infrared) phenoxazine biarsenical probes of type **104**, the alkyl substituents were fixed in rigid tetrahydroquinoline cycles (e. g. in compounds **104e**, **104h**).^[136] Another way to exclude such steric repulsions is to change the location of the dithiarsolanic rings. New locations were reported in the same paper (compounds **104c**, **104g**). In addition to the biarsenic probes, antimony analogues were also described. They possess a lower toxicity for cells (compounds **104d**, **104f**).

The use of phenoxazine-based biarsenical probes removes some spectroscopic limitations of the structure of a probe. However, it is still not possible to use some important dyes with (near) IR emission and some bright and photostable dyes with visible emission. A universal approach towards the solution of this problem was reported by Bhunia et al.^[7] It was suggested to separate the binding moiety and the fluorophore. This approach reminds one of the application of **FIAsH** for the binding of different labels to the target protein decorated with a tetracysteine tag. However, if we use **FIAsH** for this purpose, its emission spectrum may overlap with that of another fluorescent dye and an undesirable FRET effect may occur. Therefore, the non-emitting fluorescein spirolactam was used as a new binding unit in compound **105a**. Compound **105a** (SplAsH) has the same positions of the arsenic atoms as **FIAsH**. The same substitution pattern allows using the same peptide tags with four cysteine residues.

Figure 66. Biarsenical probes with non-fluorescent binding units called SplAsH.^[7,137]

Compound **105a** contains a free amino group, which could be covalently bound with any further labels. Some examples of these adducts were reported,^[7] the applied fluorophores were: *N*-methylantranilate (compound **105b**), dansyl (compound **105c**), diethylamino coumarine (compound **105d**), carboxyrhodamine 101 (compound **105e**), Alexa 594 (compound **105f**). A SplAsH derivative with a photoactivable phenoxazine dye was also prepared (compound **105g**).^[137] This probe starts to be highly fluorescent after cleavage of the NVOC-group followed by air oxidation.

2. Synthesis of precursors for SplAsH-based fluorescent labels

For the labelling of proteins (containing the tetracysteine tags) with switchable fluorescent dyes, we decided to use biarsenical probes consisting of the SplAsH unit attached to the rhodamine spiroamide residue. The difference between our biarsenical probes and the previously reported ones^[7,137] was the positions of the spectral maxima, and another photoactivation mode (for compound **SplAsH-RhS-CF**), i. e. the photoisomerization of the spirolactam instead of photocleavage, as in the case of compound **105g**.

Figure 67. New biarsenical fluorescent and photoswitchable probes.

The spectral maxima of the new probes ($\lambda_{abs}^{max} / \lambda_{fl}^{max}$, nm) are 540/560 for compounds **SplAsH-RhS-OF** and **SplAsH-RhS-CF** (after photoactivation), 542/568 for compound **SplAsH-TAMRA**. The high hydrophilicity of the fluorescent moiety in the biarsenical probes **SplAsH-RhS-OF** and **SplAsH-RhS-CF** is an advantage in the conjugation reaction with proteins and peptides, because this process usually takes place in aqueous buffers.

Scheme 48. Synthesis of SplAsH **105a**.^[7,138]

The first precursor for the SplAsH-based biarsenical fluorescent probes – compound **105a** – was prepared according to a published procedure^[7] from fluorescein (compound **106**). The methyl ester **107** was synthesized by esterification of fluorescein catalyzed by sulfuric acid.^[138] The ester **107** was isolated in 97% yield, and it was then converted into the spirolactam **109** by amidation with the monoprotected 1,2-diaminoethane **108**. Electrophilic substitution of the two aromatic protons with mercuric acetate gave the bis-mercuric spirolactam **110** in high yield (90%). The catalytic transmetallation of compound **110** with arsenic chloride in the presence of palladium acetate followed by closure of the dithiarsolanic ring gave the Boc-protected SplAsH (compound **111**) in moderate yield (44% vs. 95% in the literature). Deprotection of compound **111** with trifluoroacetic acid resulted in SplAsH **105a**.

Two of the three required dyes with an amino-reactive group (*N*-hydroxysuccinimidyl ester), were prepared as described in the literature.^[8,139,140] Before that, the linker for binding the water-soluble rhodamine with SplAsH **105a** was synthesized.

Scheme 49. Synthesis of the short bifunctional linker **114-Me**.

As a starting material, the commercially available *Z*-β-alanine (**112**) was chosen. After twofold (*N*, *O*) methylation and cleavage of the *Z*-group by hydrogenolysis, methyl *N*-methyl-β-alaninate (**114-Me**) was produced.^[8] The yields in both steps were high (94% and 86%).

Scheme 50. Synthesis of the amino-reactive derivatives of the water-soluble Rhodamine S (**116**) – compounds **118-R**.^[8,139,140]

For the synthesis of the NHS-ester of the fluorescent version of the water-soluble Rhodamine S **118-Me**,^[8] rhodamine Q **115** was used as a starting material. The latter was mixed with 30% oleum in order to introduce two sulfonic acid groups.^[8] Thus, Rhodamine S **116**^[8] was produced in good yield (67%). Then the *N*-hydroxysuccinimidyl ester was prepared from the carboxylic acid **116** *in situ* followed by the reaction with compound **114-Me**, which afforded the methyl ester **117-Me-Me**^[8] in good yield (60%). The saponification of the methyl ester **117-Me-Me** was carried out under mild conditions, producing the carboxylic acid **117-Me-H**^[8] in high yield (90%). Treatment of the acid **117-Me-H** with TSTU provided the *N*-hydroxysuccinimidyl ester **118-Me**.^[8] The preparative yield of this ester was moderate (43% after purification by HPLC).

The non-fluorescent *N*-hydroxysuccinimidyl ester **118-H**^[140] was prepared in a similar way as compound **118-Me**. Amidation of the *in situ* formed *N*-hydroxysuccinimidyl ester of the carboxylic acid **116** with the commercially available methyl ester of β -alanine (compound **114-H**) afforded the methyl ester **117-H-Me**^[139] in low yield (18%). After saponification of the methyl ester **117-H-Me** under the same conditions as for compound **117-Me-Me**, the trisodium salt was obtained and converted into the free acid **117-H-H**^[140] by treatment with a

strongly acidic ion-exchange resin in its H^+ -form. In the last step, the compound **118-H**^[140] was isolated by HPLC as the product of the reaction between the acid **117-H-H** and TSTU. The yield of the NHS-ester **118-H** was moderate (51%).

3. Synthesis of reactive fluorescent labels

3.1. Synthesis of the water-soluble labels

Initially, we planned to prepare the required compound **SplAsH-RhS-OF** by a reaction between NHS-ester **118-Me** and the amine **105a** in dichloromethane and in the presence of an organic base.

Scheme 51. Preparation of two biarsenical probes with hydrophilic rhodamines.

However, due to the low solubility of compound **118-Me** in dichloromethane, DMF was used instead. The target product was observed in this case, but the conversion was very low (only 7%). A higher conversion (about 74%) was achieved after optimization of the reaction conditions: the order of the addition of components, and the nature of solvents. The final product – compound **SplAsH-RhS-OF** – was difficult to isolate from the reaction mixture. It was found to be extremely unstable. Preparative TLC, as well as column chromatography was not suitable for purification (such methods were used for the isolation of the similar

compounds^[7]). The main reason for this instability is probably the presence of the dithiarsolanic rings and the sulfonic acid residues in the same molecule. To protect the product **SplAsH-RhS-OF**, we needed to minimize its contact with silica gel. Therefore, reversed-phase HPLC was used for the isolation and purification. The product was successfully isolated, and its purity was found to be 89% (HPLC by area). However, during the evaporation of solvents (acetonitrile and water) in a freeze dryer, the purity went down to 29% (HPLC by area). The most obvious reason is the decomposition due to the presence of trifluoroacetic acid (TFA) in the eluate. To neutralize the TFA, we collected the eluate in solutions of the organic buffer – ammonium acetate. This helped us to save most of the isolated compound, and the content of product **SplAsH-RhS-OF** after freeze drying was found to be 85%.

Another factor also decreased the overall yield; namely, the preparation of the reaction mixture for the HPLC isolation procedure, which first step requires evaporation of the solvents from the reaction mixture (CH_2Cl_2 , Et_3N and DMF). For a certain time, the product remains in the reaction mixture without a base, and in a base absence, the content of **SplAsH-RhS-OF** drops from 74 to 17%. In order to decrease the loss of the target compound during evaporation of the solvents, we minimized the applied amount of solvents in the reaction. As a result, the content of the target compound in the reaction mixture was found to be 33%.

The last improvement in the purification procedure was achieved, when the temperature of the HPLC column was reduced to 6 °C. As a result, the purity of the isolated product was increased to 96% (vs. 89% at 25 °C).

The second target compound – **SplAsH-RhS-CF** – was prepared and isolated similarly to **SplAsH-RhS-OF**. After the solvent removal, the reaction mixture contained 40% of the target compound (HPLC by area), and the purity of the isolated product **SplAsH-RhS-CF** was found to be 81% (HPLC by area).

3.2. Synthesis of the TMR derivative intended for the localization of the tagged proteins in mitochondria

The third fluorescent biarsenical probe had to have the heightened mitochondrial localization. Positively charged TMR-derivatives are known to label mitochondria.^[141] Thus, we decided to produce the compound **SplAsH-TAMRA** (Scheme 52), which should be transported to the tagged mitochondria owing to the presence of a TMR moiety, and it should be bound to the tetracysteine tag in the mitochondrial proteins owing to the presence of a SplAsH component.

Scheme 52. Preparation of compound **SplAsH-TAMRA**.

We prepared the adduct from the compound **105a** and the commercially available **6-TAMRA,SE[®]** (**119**) under similar conditions, as for compounds **SplAsH-RhS-CF** and **SplAsH-RhS-OF** described above. The isolation of the conjugate **SplAsH-TAMRA** was found to be much easier than the isolation of the hydrophilic analogues. In the absence of sulfonic acid residues in the molecule of **SplAsH-TAMRA** the purification of this compound could be carried out by conventional column chromatography (on a reversed phase column).

4. Spectroscopic control of the prepared biarsenical probes

To confirm the binding ability of the target products (**SplAsH-RhS-CF** and **SplAsH-RhS-OF**), we carried out competitive spectroscopic experiments. We investigated the binding abilities of the SplAsH derivatives (**SplAsH-RhS-CF** and **SplAsH-RhS-OF**) and compared them with the binding ability of **FlAsH** (compound **103a**). In the first experiment, it was established that the position of the fluorescence maximum of compound **SplAsH-RhS-OF** was at 557 nm.

In the second experiment, the position (529 nm) and the intensity of the fluorescence signal of a 1 μ M aqueous solution of compound **103a** was determined. The reaction mixture which contained **FlAsH** and the decapeptide GSSGCCPGCC in a 1:1 ratio (both components in 1 μ M concentration) showed a five times higher fluorescence intensity.

Figure 68. Comparison of the binding ability of **SplAsH-RhS-OF** and of **FIAsH** with the decapeptide GSSGCCPGCC: a) the dark base blue line represents the fluorescence signal of the peptide (almost non-fluorescent); b) the pink line corresponds to the fluorescence of a 1 μ M aqueous solution of **FIAsH**, c) the red line displays the fluorescence signal of a 1:1-mixture of **FIAsH** and the decapeptide (concentrations of the both components are the 1 μ M), d) the light blue line represents the result of the competition experiment: **FIAsH** : **SplAsH-RhS-OF** : peptide = 1:1:1. The intensity of the fluorescence signal is measured in “cps” (counts per second).

The third fluorescence spectrum displays the emission signal of the three-component mixture – **FIAsH**, **SplAsH-RhS-OF** and the decapeptide – in a 1:1:1 equimolar ratio. These components were mixed in a competitive mode, i. e. the peptide was added to the mixture of **FIAsH** and **SplAsH-RhS-OF** in the buffer solution. As a result, the fluorescence spectra possessed two maxima which were attributed to **FIAsH** (529 nm) and to **SplAsH-RhS-OF** (557 nm). However, the weaker absolute intensity of the **FIAsH** band (than in the case of the pure **FIAsH**-peptide complex) can be attributed to the non-bound form of **FIAsH** (or to a mixture of the non-bound form and a small amount of the bound form). Unfortunately, the superposition of the two bands from the (unbound) **FIAsH** and **SplAsH-RhS-OF** did not allow us to estimate the quantitative parameters of the binding process.

Towards this goal, we used the compound **SplAsH-RhS-CF** that has a similar structure, but is not fluorescent at 400-600 nm. As a consequence, in the competition experiment only a decrease in the intensity of the fluorescence maximum of **FIAsH** should be observed.

Figure 69. Comparison of the binding ability of **SplAsH-RhS-CF** and **FIAsH** with the decapeptide GSSGCCPGCC: a) the dark blue line represents the background fluorescence from **SplAsH-RhS-CF** (almost no emitted light could be seen); b) the pink line displays the fluorescence of the **FIAsH** solution, c) the red line gives the fluorescence intensity of a mixture of **FIAsH** and the decapeptide in a molar ratio of 1:1, d) the light blue line is a competition experiment (**FIAsH**: **SplAsH-RhS-CF**: peptide =1:1:1). The measure of the intensity of the fluorescence signal is “cps” (counts per second).

The presence of the two sulfonic acid residues in the structure of compound **SplAsH-RhS-CF** did not substantially increase the solubility of this compound in water. Thus, for the measurements, we applied a mixture of the PBS buffer and DMF (in a volume ratio of 1:1). Under these conditions, the fluorescence maximum of **FIAsH** was shifted to 542 nm. The intensity of the fluorescence signal of the mixture consisting of **FIAsH** and the decapeptide increased 16.4 times in comparison with a solution of the pure **FIAsH** in the same solvent mixture (although, binding of **FIAsH** with the same peptide in water produced only a 5-fold increase in the fluorescence signal intensity). The last fluorescence spectrum represents the emission of a three-component mixture of **FIAsH**, **SplAsH-RhS-CF** and the peptide in an equimolar ratio. These components were mixed in the following order: the peptide was added to the mixture of **FIAsH** and **SplAsH-RhS-CF** in aqueous DMF. The resulting fluorescence spectra possessed only one band at 542 nm, which was 3 times more intensive than the fluorescence band of a solution of the pure **FIAsH** (without the peptide). If we denote the fraction of the unbound **FIAsH** in the mixture of the competition experiment as X , the bound

FLAsH as $1-X$ and the fluorescence of the solution of pure **FLAsH** as A , then the fluorescence of the FLAsH-peptide complex is $16.4*A$ and the fluorescence in the competition experiment is $3*A$. Then from the equation $3*A = X*A + 16.4*A(1-X)$ we calculate that $X = 13.4/15.4 = 0.87$. This means, that most of the **FLAsH** is in the non-bound state, and the ratio of the free **FLAsH** to the bound **FLAsH** is about 7:1. Thus, most of the decapeptide was bound with the non-fluorescent SplAsH derivate.

5. Bioimaging tests of the prepared biarsenical probes

Before any experiments with living cells could be conducted, it was necessary to check the binding ability of the SplAsH derivatives *in vitro*. Therefore, a TetCys-mut-GFP-TetCys protein was chosen as the test substrate. This represents an isolated Green Fluorescent Protein with two point mutations that disrupt its ability to emit light and with additional tetracysteine motifs attached to *N*- and *C*-Terminals.

Figure 70. Absorption spectra of the collected fractions from size exclusion chromatography performed after incubation of TetCys-mut-GFP-TetCys-protein with the compound **SplAsH-RhS-OF**. The numbers on the right side of the spectra are the fraction numbers (every fraction was 0.5 mL). At the beginning we can observe the fractions which contain the unknown substrates (for example fraction number 4 has in the absorption spectrum a band at 550 nm, that can indicate the presence of **SplAsH-RhS-OF** (or products of its decomposition) in this fraction). Then, in the absorption spectra of the fractions 13–18, where the substances with higher molecular weight should be present, a band at 280 nm was observed (this band is marked with green arrows). These fractions contain the TetCys-mut-GFP-TetCys-protein.

We tried to isolate the conjugate of the above mentioned protein with the compound **SplAsH-RhS-OF** using size exclusion chromatography with a spectroscopic control. Unfortunately, we did not find any fractions displaying the absorption bands of the protein

TetCys-mut-GFP-TetCys (at 280 nm) and the compound **SpIAsH-RhS-OF** (at 550 nm) (see Figure 70).

As a positive control, a similar experiment was done with the commercially available FIASH (Lumio-Green/Invitrogen). In this experiment, the **FIAsH** was clearly bound to the tetracysteine containing protein (see Figure 71).

Figure 71. Absorption spectra of the collected fractions from the size exclusion chromatography column obtained after the conjugation experiment between TetCys-mut-GFP-TetCys-protein and **FIAsH**. The fractions 4 and 5 both contain characteristic bands attributed to TetCys-mut-GFP-TetCys-protein, and to **FIAsH**; their maxima are marked with black arrows).

After that, we performed another conjugation experiment, in which a preliminary treatment of the protein with the TCEP reagent (for reduction of the disulfide bonds) was performed. As an analytical method, the sodium dodecyl sulfate polyacrylamide gel electrophoresis (SDS-PAGE) was chosen.

Figure 72. SDS-PAGE of TetCys-mut-GFP-TetCys-protein labelled with **FlAsH** and the compound **SplAsH-RhS-OF**. The picture A is taken under UV light (left) and the picture B after staining with Roti[®]-Blue (right). The number of lanes is the same in both pictures. By the special Roti[®]-Blue dye we visualized the protein bands. Lanes **1** and **10** contain a set of molecular weight markers, lanes **8** and **9** contain big bands which are visible only under UV light and can be attributed to **SplAsH-RhS-OF** (and its decomposition products), **7** – the band of mutated non-fluorescent GFP, **6** – the band of TetCys-mut-GFP-TetCys-protein (also mutated GFP, but with two tetracysteine tags attached to the *N*- and *C*-terminals), lane **5** corresponds to the experiment with mutated GFP and **SplAsH-RhS-OF** [there are two bands: the first one (on picture B) is attributed to the non-fluorescent mutated GFP, the second one (on picture A) is a big fluorescent band of **SplAsH-RhS-OF** that indicates the absence of binding of the biarsenical probe **SplAsH-RhS-OF** to the protein without a tetracysteine tag), **4** – the same experiment as in the lane **5**, but the biarsenical probe **FlAsH** was used for the labelling (in this lane, only the band of the mutated GFP-protein is presented, because the non-bound **FlAsH** is non-fluorescent), **3** – the main experiment with TetCys-mut-GFP-TetCys-protein and biarsenical probe **SplAsH-RhS-OF** (two fluorescent bands can be seen: the low band corresponds to the trace of the initial biarsenical probe **SplAsH-RhS-OF**, the upper band corresponds to the complex of TetCys-mut-GFP-TetCys-protein with the biarsenical probe **SplAsH-RhS-OF**, the protein nature of which was confirmed by the blue band in the left picture), **2** – additional control experiment with TetCys-mut-GFP-TetCys-protein and biarsenical probe **FlAsH** (only one fluorescent band is seen, namely the complex of TetCys-mut-GFP-TetCys-protein with the biarsenical probe **FlAsH**, the protein nature of which was confirmed by the blue band in the left picture).

The presence of the bright fluorescent band (visible upon UV light illumination) in the expected area of the SDS-PAGE gel indicate, that a complex between TetCys-mut-GFP-TetCys-protein and the compound **SplAsH-RhS-OF** was formed and could be separated by the SDS-PAGE method.

Figure 73. SDS-PAGE of isolated mitochondria from a yeast strain that expresses a triple tetracysteine tagged Por1 protein and is labelled with compound **SplAsH-RhS-OF** and compound **SplAsH-TAMRA** (negative control – wild type mitochondria, positive control – **FlAsH**). Lanes: **6** – experiment with the isolated mitochondria with the triple tetracysteine tagged version of Por1 (one of the proteins of the outer mitochondrial membrane) and biarsenical probe **SplAsH-RhS-OF** (the red arrow points to the fluorescent band of the labelled mitochondrial protein that indicates the binding of the biarsenical probe **SplAsH-RhS-OF** with the tetracysteine tagged version of the mitochondrial protein Por1), **5** – experiment with wild-type mitochondria and **SplAsH-RhS-OF** (the red arrow points to the very pale fluorescent band of the unspecifically labelled mitochondrial protein; the absence of the fluorescent band at the same place as in lane **6** confirms the binding ability of **SplAsH-RhS-OF**), **4** – the same experiment as in the case of lane **6**, but with biarsenical probe **SplAsH-TAMRA** (the red arrow points to the fluorescent band of the labelled mitochondrial protein that indicates binding of the biarsenical probe **SplAsH-TAMRA** to the tetracysteine tagged version of the mitochondrial protein Por1), **3** – experiment with a wild-type mitochondria and **SplAsH-TAMRA** (the red arrow points to the very pale fluorescent band of the unspecifically labelled mitochondrial protein; the absence of the fluorescent band at the same place as in the lane **4** confirms the binding ability of **SplAsH-TAMRA**), **2** – additional control experiment with the triple tetracysteine tagged version of the mitochondrial protein Por1 and biarsenical probe **FlAsH** (the red arrow points to the fluorescent band of labelled

mitochondrial protein that confirms the presence of the tetracysteine tags in the used mitochondrial protein Por1 to which the biarsenical probe **FIAsH** are bound), **1** – experiment with wild-type mitochondria and **FIAsH** (the red arrow points to the very pale fluorescent band of the unspecifically labelled mitochondrial protein; the absence of the fluorescent band at the same place as in lane **2** confirms the binding ability of **FIAsH**).

The labeling experiments with the isolated mitochondria expressing a three TetCys-tagged version of Por1 (one of the proteins in the outer mitochondrial membrane), were also successful. These mitochondria were successfully labelled with the two biarsenical probes: **SplAsH-RhS-OF** and **SplAsH-TAMRA**. These facts were confirmed in the same manner as earlier, i. e. by observation of the bright fluorescent lanes upon UV light illumination in the required area of an SDS-PAGE plate (Figure 73).

Therefore, we have confirmed, that the specific binding of our SplAsH derivatives to the tetracysteine tags in proteins could indeed be achieved.

Unfortunately, the attempted *in vivo* labelling of the mitochondrial proteins containing tetracysteine tags failed to produce positive results.

Figure 74. Confocal image of yeast cells, stained by means of electroporation with **SplAsH-RhS-OF** (left picture) and the recorded fluorescence of the same cells caused by the mitochondrial targeted Blue Fluorescent Protein (m-BFP) (right picture). In the right picture, we can see mitochondrial network (blue), but in the left picture we can see only unspecific background staining, because only random red spots inside the cells are seen.

A yeast strain expressing the mitochondrial targeted, mutated and tetracysteine tagged GFP and additionally expressing a mitochondrial targeted Blue Fluorescent Protein was the first object of staining. These yeast cells were stained by electroschock according to a standard protocol^[142] with FIAsH (as a positive control) or with **SplAsH-RhS-OF**. While the yeast

mitochondria were very well stained with **FlAsH**, **SplAsH-RhS-OF** (see Figure 74) showed nearly no mitochondrial staining at all. A similar experiment which was carried out with **SplAsH-TAMRA** did not show any improvements compared to **SplAsH-RhS-OF**.

Figure 75. Confocal image of PFA (polyformaldehyde) fixed yeast cells, which were permeabilized by treatment with Triton – X100 and stained with **SplAsH-RhS-OF** (left picture) and the detected fluorescence of the same cells from the mitochondrial targeted m-BFP (right picture). In the right picture, we can see the bright blue mitochondrial network, which could be attributed to the cell mitochondria, but in the left picture we cannot see clear mitochondrial staining, because in this picture the entire cell is red-colored inside (without any separations of the organells).

The same yeast strain employed for the electrostaining was now fixed with 8 % PFA and afterwards permeabilized with 0.5 % Triton – X100. Neither **SplAsH-RhS-OF** (Figure 75) nor **SplAsH-TAMRA** showed any significant degree of mitochondrial staining.

Figure 76. Confocal image of the PFA-fixed yeast cells permeabilized by treatment with Triton – X100, treated with TCEP treatment and stained with the **SplAsH-TAMRA**. In this

picture, also the entire cells are red-colored inside (without any separations of the organelles, besides the strange tubulin-like artefacts, which look like a tubular structure inside the cells).

In the next series of experiments, the yeast cells expressing triple tetracysteine-tagged α -Tubulin was used. Then, these cells were fixed and permeabilized as before, but additionally treated with 1 mM TCEP to reduce disulfide bonds. They were afterwards stained with **FlAsH**, **SplAsH-RhS-OF**, or **SplAsH-TAMRA** (see Figure 76). As a negative control, a wild type strain was used. Unexpectedly, the TCEP treatment induced an α -Tubulin-like staining artefact in the yeast cells regardless of the applied dye that can also be seen in wild-type cells.

Incubation of the TetCys-mut-GFP-TetCys expressing cells mentioned before with **SplAsH-RhS-OF** and **SplAsH-TAMRA** did not result in a clear mitochondrial staining, too.

Thus, higher numbers of tetracysteine tags in the one protein and the change of the type of protein in the combination with the TCEP pre-treatment also did not help to increase the selectivity of labelling by our biarsenical probes *in vivo*.

Experimental Part

1. General Remarks

All chemicals obtained from commercial sources were used without additional purification. The catalyst, which was used for reduction of nitro compounds and debenzylation is 10% Pd/C (VWR International, oxidized form).

All reactions performed according the General Procedures 1, 3, 4 and 5 (**GP1**, **GP3**, **GP4**, **GP5**) were carried out in dry Schlenk flasks which were evacuated and flushed with argon three times.

NMR spectra were recorded on *Varian Unity 300* and *Varian Mercury 300* (300 MHz for ^1H , 75.5 MHz for ^{13}C), *Varian INOVA 500* (500 MHz for ^1H and 125.7 MHz for ^{13}C NMR) or *Varian INOVA 600* (600 MHz for ^1H NMR) spectrometers in CDCl_3 if not otherwise specified. Assignments of the ^{13}C -signals to $\text{CH}_3(\text{CH})$ and $\text{CH}_2(\text{C}_q)$ groups were made by APT (Attached Proton Test) measurements. Chemical shifts (δ) are given in ppm. All spectra are referenced to tetramethylsilane as an internal standard ($\delta = 0$ ppm) using the signals of the residual protons of deuterated solvents: $\delta = 7.26$ ppm for CHCl_3 , 3.31 ppm for CHD_2OD and 2.50 ppm for $[\text{D}_5]\text{DMSO}$. Multiplicities of the proton signals are described as follows: s = singlet, d = doublet, t = triplet, q = quartet, quint = quintet, m = multiplet, br = broad. Coupling constants (J) are given in Hz.

Melting points (uncorrected) were determined in capillaries using a *SMP 10* apparatus (Bibby Sterling LTD, UK).

Electron ionization mass spectra (EI-MS, 70 eV) and chemical ionisation mass spectra (CI-MS, 200 eV, reactant gas NH_3) were measured with a *Finnigan MAT 95* spectrometer. Electrospray ionization mass spectra (ESI-MS) were recorded with a *LCQ Finnigan* spectrometer. High-resolution mass spectra (HR-MS) were measured with *Bruker APEX IV 7T FT-ICR* instrument, and with ESI-TOF spectrometer *microTOF (Bruker)* equipped with the “Apollo” ion source.

Absorption and fluorescence stationary measurements were carried out with *Varian Cary 4000* UV-Vis spectrophotometer, and *Varian Cary Eclipse* fluorescence spectrophotometer, respectively. Some of the fluorescence measurements were carried out using *Fluorolog 3-22* (HORIBA Jobin Yvon GmbH, Unterhaching, Germany) emission spectrometer with double monochromator for the excitation and emitted light. The quartz cuvettes with 0.1 and 1 cm path lengths were used. Emission spectra were corrected for the instrument response. Irradiation of the compound **40-H** to drive the photochromic reactions was performed with a

200W Mercury lamp (LOT-Oriel GmbH & Co. KG, Darmstadt, Germany) equipped with a monochromator and band-pass filter centered at 366 nm (UG1 – 3 mm, Schott).

HPLC-System (Knauer): Smartline pump 1000 (2×), UV-detector 2500, column thermostat 4000, mixing chamber, injector with 20 and 100 µL loops for the analytical and preparative columns, respectively; 6-port-3-channel switching valve; analytical column: Eurosphere-100 C18, 5 µm, 250×4 mm; preparative column: Eurosphere-100 C18, 5 µm, 250×8 mm; solvent A: H₂O + 0.1% v/v TFA, solvent B: MeCN + 0.1% v/v TFA; temperature 25 °C (if not specified otherwise).

Analytical TLC was performed on aluminium plates precoated with silica gel 60/F₂₅₄ (VWR International GmbH, Darmstadt, Germany), and on glass plates precoated with silica gel RP-18W/F₂₅₄ (Macherey-Nagel, Düren, Germany). Spots were visualized under ultraviolet light (254 nm) and / or developed by treatment with molybdenum phosphoric acid solution (5% in EtOH), aq. KMnO₄ or iodine vapors. Flash chromatography was performed using VWR SiO₂, grade 60, 0.04–0.063 mm. Reversed phase chromatography was performed on Polyoprep 60–50 C18 (Macherey-Nagel, Düren, Germany).

Anhydrous THF was distilled over sodium benzophenone ketyl. Organic solutions were dried with MgSO₄ or Na₂SO₄. All reactions were carried out with magnetic stirring under positive pressure of argon or nitrogen using the standard vacuum – inert gas manifold, unless stated otherwise.

In the section 3.4 of Chapter 2 all measurements of the absorption and fluorescence spectra at various pH values of aqueous buffers were carried out after waiting period for 12 h after preparation of solutions. Other spectroscopic measurements in this section were carried out without waiting period.

For all experiments in the section 4 of Chapter 3: a) with compound **SplAsH-RhS-OF** was used 1×PBS buffer with addition of 2-mercaptoethanol (1 mM); b) with compound **SplAsH-RhS-CF** was used the mixture 0.2×PBS buffer and DMF in the ratio 1:1 with addition of 2-mercaptoethanol (1 mM); the fluorescence spectra were measured after waiting period for 12 h. 1×PBS buffer mixture: 137 mM NaCl, 2.68 mM KCl, 10.0 mM Na₂HPO₄, 1.76 mM KH₂PO₄.

2. Preparation of Known Compounds

2-(4-(*N,N*-Diethylamino)-2-hydroxybenzoyl)-benzoic acid (**37**) and *N,N*-diethylrhodol **39-H** were synthesized as described for the similar compounds.^[93] 1-Aza-2,3-benzo-15-

crown-5 (**45**) was prepared according to the published procedure.^[96] 2-[2-[2-(2-Chloroethoxy)-ethoxy]-ethoxy]-ethanol (**53**) was prepared according to Amabilino.^[98] 1,4-Bis(benzyloxy)benzene (**56**), 1,4-bis(benzyloxy)-2-nitrobenzene (**57**) and 4-(benzyloxy)-2-nitrophenol (**58**) were synthesized according to Gryniewicz.^[35b] *N*-(3-Methoxyphenyl)-1,4,7,10-tetraoxa-13-azacyclopentadecane (**67**) was prepared by a procedure of Buchwald-Hartwig amination.^[103] 2-(2,4-Dihydroxybenzoyl)-benzoic acid (**69**) was synthesized according to the published procedure.^[64] 4-Methoxy-5-nitrophthalic anhydride (**74**) and 4,5-dinitrophthalic acid (**78**) were prepared according to the published procedure.^[106] 4-Methoxyphthalic acid (**81**) was prepared from 3,4-dimethylphenyl methyl ether **80** according to the published oxidation method.^[108] 4,5-Dichlorophthalic acid anhydride (**86**) and 4-hydroxy-5-nitro-*N*-methylphthalimide (**88**) were synthesized according to Caswell.^[111] 4,5-Dichloro-*N*-methylphthalimide (**87**) was prepared according to the published procedure.^[112] Potassium salt of 5-hydroxy-2-methyl-6-nitro-1*H*-isoindole-1,3(2*H*)-dione (**89**) was synthesized according to the published procedure.^[113] 1,11-Diiodo-3,6,9-trioxaundecane (**91**) was prepared according to the published procedure.^[114a] 2-[2-[2-(2-Trityloxyethoxy)-ethoxy]-ethoxy]-ethanol (**94**) and 2-[2-[2-(2-trityloxyethoxy)-ethoxy]-ethoxy]-ethyl mesylate (**95**) were synthesized according to Pilkington-Miksa.^[116] Methyl ester of fluorescein (**107**) was prepared according to the published procedure.^[138] Fluorescein spiroamide **109**, its mercury derivative (**110**), Boc-protected SplAsH (**111**) and SplAsH (**105a**) were synthesized according to Bhunia.^[7] Methyl ester of *N*-benzyloxycarbonyl-*N*-methyl- β -alanine (**113**) and methyl ester of *N*-methyl- β -alanine (**114-Me**) were prepared according to the published procedures, Rhodamine S (**116**), the methyl ester **117-Me-Me**, the carboxylic acid **117-Me-H** and its *N*-hydroxysuccinimidyl ester **118-Me** were synthesized according to the published procedures.^[6] The methyl ester **117-H-Me** was prepared according to Belov.^[139] Acid **117-H-H** and the NHS-ester **118-H** were synthesized according to Polyakova.^[140]

Figure 77. Numbering of rhodols (**39-Me**, **Ia**, **Ib**, **Ic**, **Ic-Me**•2/TsOH, **70**) and rhodolspiroadamides (**47-H**, **47-Me**).

3. Experimental procedures

General procedure for the synthesis of xanthenes (35, 1a, 1b, 1c•2/3TsOH, 70) (GP1): A mixture of the corresponding phthalic anhydride (1 mmol) or benzophenone (1.5 mmol) and *p*-toluene sulfonic acid monohydrate (8–12 mol%) was loaded into the flask equipped with a reflux condenser and a bubble counter. Then the solution of *m*-aminophenol (1.5 mmol in the case of reaction with phthalic anhydride and 1.0 mmol in the case of reaction with benzophenone) in propionic acid (1.5–6 mL) was added. The reaction mixture was heated at 150 °C for 24–48 h under argon or nitrogen. The solvent was evaporated in vacuo and the residue was purified by chromatography on silica gel.

General procedure for the reduction of a nitro group (the synthesis of compounds 48a, 97, 100) (GP2): The 10% Pd/C (20 w/w % to the amount of the substance to be reduced) and MeOH (THF, EtOAc) (5–15 mL) were placed into the Schlenk-flask equipped with septa. The mixture was flushed with hydrogen and stirred vigorously to activate the catalyst. A solution of the nitro compound (1 mmol) in MeOH (THF, EtOAc) (5–10 mL) was introduced through a septum. The solution was stirred for 4–8 h at room temperature using the balloon with hydrogen. Then the hydrogen gas was replaced by argon, and the mixture was filtered through Celite[®]. The filter-cake was washed with MeOH (THF, EtOAc) (3×20 mL) and the solvent was removed in vacuo. The product was purified by chromatography on silica gel.

General procedure for the monotosylation of alcohols (the synthesis of compound 101) and ditosylation of aminoalcohols (the synthesis of compounds 61, 98) (GP3): To a solution of alcohol (1 mmol) or aminoalcohol (1 mmol) in a dry pyridine (5 mL), tosyl chloride (1.5–2.05 mmol) was added in small portions at 0 °C, and the reaction mixture kept at 4 °C for 3–4 days. Then it was poured onto the mixture of crushed ice (20 mL) and concentrated hydrochloric acid (6 mL). The mixture was warmed-up to room temperature and extracted with CH₂Cl₂ (3×20 mL). The combined organic solutions were washed with brine (50 mL), dried and concentrated in vacuo. The residue was purified by chromatography on silica gel.

General procedure for the crown ether ring closing (the synthesis of compounds 62, 63a, 99) (GP4): A solution of aminotosylate (1 mmol) or ditosylate (1 mmol) in dry DMF (4–10 mL) was prepared in the Schlenk-flask equipped with a septum. Caesium carbonate (1.05 mmol) was added to the flask at room temperature, and the reaction mixture was heated at 90

°C for 24–39 hours. The solvent was evaporated in vacuo, and the residue was diluted with CHCl₃ (30 mL) and filtered through Celite.[®] The filter-cake was washed with CHCl₃ (3×10 mL), and the solvent was removed in vacuo. The residue was purified by chromatography on silica gel.

General procedure for debenzylation (the synthesis of compounds 42a, 42b, 42c) (GP5): 10% Pd/C (20 w/w % to the amount of the substance to be debenzylated) and MeOH (4 mL) or AcOH (1–3 mL) were placed into a Schlenk-flask equipped with a septum. The mixture was flushed with hydrogen and stirred vigorously to activate the catalyst. A solution of benzyl ether (1 mmol) in MeOH (8 mL) or AcOH (2–3 mL) was introduced through a septum. The solution was hydrogenated overnight at room temperature under hydrogen filled into a balloon attached to the reaction flask. Then the hydrogen gas was replaced by argon, and the mixture was filtered through Celite.[®] The filter-cake was washed with MeOH or AcOH (3×20 mL), and the solvents were removed in vacuo. Then the obtained oil was diluted with CH₂Cl₂ and the solvent was evaporated once more. The latter operation was repeated two times. The product was isolated as a brownish oil which oxidized easily in air.

General procedure for the syntheses of the SplAsH adducts (SplAsH-RhS-OF, SplAsH-RhS-CF) (GP6): To a solution of an NHS-ester of the rhodamine derivative (7–8 μmol) and Et₃N (21 μmol) in dry DMF (1 mL), the solution of compound **105a** (21 μmol) in CH₂Cl₂ (0.4 mL) was added via a syringe, and the reaction mixture was stirred at room temperature overnight. Then all volatile materials were removed in vacuo (without heating). The residue was purified by reversed-phase preparative HPLC with MeCN / H₂O mixture (40:60 → 100:0, 25 min, 7 °C). The fractions were collected into the test tubes. Every tube (V = 8 mL) contained the cold (4 °C) aqueous solution of AcONH₄ (25 μL, 21 M). After filling of a tube, its content was immediately transferred into the cold flask (–78 °C). Then the solvent and AcONH₄ were removed by freeze drying. The product was isolated as a rosy solid, which could be stored at –20 °C for a long time (several months).

3-(*N,N*-Diethylamino)-4-methoxyaniline (33): 3-(*N,N*-diethylamino)-4-methoxyacetanilide

(**32**) (5.0 g, 21 mmol) and 19% aq. HCl (30 mL) were placed into the flask equipped with a reflux condenser. The reaction mixture was refluxed for 60 h. After cooling to 0 °C, the mixture was neutralized with 4.15 M aq. NaOH (50.7 mL) and was extracted with CHCl₃ (4×80 mL). The combined organic solutions

were dried and concentrated in vacuo. The residue was purified by chromatography on silica gel (200 g) with CH₂Cl₂ / MeOH mixture (20:1) as an eluent, and the title compound was isolated as a brown oil which easily oxidized in air (3.26 g, 80%). ¹H NMR (300 MHz): δ = 1.01 (t, ³J = 7.2, 6 H), 3.10 (q, ³J = 7.2, 4 H), 3.35 (br. s, 2 H, NH₂), 3.76 (s, 3 H, OMe), 6.27 (dd, ³J = 7.8, ⁴J = 2.4, 1 H), 6.34 (d, ⁴J = 2.4, 1 H), 6.67 (d, ³J = 7.8, 1 H) ppm.

3-(*N,N*-Diethylamino)-4-methoxyphenol (31): Compound **33** (1.0 g, 5.2 mmol) was dissolved in 1.5 M aq. H₂SO₄ (6.5 mL), cooled to 0 °C, and the solution of NaNO₂ (0.44 g, 6.4 mmol) in water (1 mL) was added carefully dropwise.

The mixture was stirred for 10 min. Then the several crystals of urea were added. The solution of diazonium hydrogen sulfate **34** was heated at 100 °C for 6 h. After cooling to 0 °C, the mixture was neutralized with 1 M aq. NaOH and was extracted with CH₂Cl₂ (3×40 mL). The combined organic solutions were dried and concentrated in vacuo. The residue was purified by chromatography on silica gel (100 g) with CH₂Cl₂ / MeOH mixture (20:1) as an eluent, and the title compound was isolated as a brownish solid, which easily oxidized in air (0.35 g, 34%); m. p. 86 °C (hexane/ CH₂Cl₂). ¹H NMR (300 MHz): δ = 0.96 (t, ³J = 7.2, 6 H), 3.07 (q, ³J = 7.2, 4 H), 3.72 (s, 3 H, OMe), 6.40 (dd, ³J = 9.0, ⁴J = 3.0, 1 H), 6.46 (d, ⁴J = 3.0, 1 H), 6.65 (d, ³J = 9.0, 1 H) ppm. ¹³C NMR (75.5 MHz): δ = 11.8 (2×CH₃CH₂), 45.8 (2×CH₃CH₂), 55.9 (CH₃O), 108.4 (CH), 109.6 (CH), 112.5 (CH), 139.9 (C), 147.7 (C), 149.8 (C) ppm. EI-MS, *m/z* (rel. int., %): 195 (54) [M]⁺, 180 (100) [M – CH₃]⁺, 164 (13), 151 (27), 136 (15). HR-MS (ESI) negative mode: found: 194.1188; calcd. for C₁₁H₁₇NO₂: 194.1181 [M – H][–], positive mode: found: 196.1337, 218.1158; calcd. for C₁₁H₁₇NO₂: 196.1338 [M + H]⁺, 218.1157 [M + Na]⁺.

3,6-bis(*N,N*-Diethylamino)-2,7-dimethoxy-9-(3'-carboxyphenyl)xanthene (35): According

to the GP1, phthalic anhydride (0.15 g, 1.0 mmol), *p*-toluene sulfonic acid monohydrate (23 mg, 12 mmol) and compound **31** (0.30 g, 1.5 mmol) was heated for 24 h. After purification by chromatography on silica gel (100 g) with CH₂Cl₂ / MeOH mixture (10:1 → 4:1), the title compound was isolated as violet foam (70 mg, 18%); decomp. > 300 °C. HPLC: 50/50 → 0/100 (A/B) in 25 min, 1 mL/min, 25 °C, *t_R* = 3.8 min, detection at 254 nm. ¹H NMR (300 MHz, [D₆]DMSO): δ = 1.02 (t, ³J = 7.5, 12 H), 3.21 (q, ³J = 7.5, 8 H), 3.46 (s, 6 H, OMe), 6.03 (s, 2 H, 2×CH, H-4/5), 6.74 (s, 2 H, 2×CH, H-1/8), 7.32 (d, ³J = 7.8, 1 H, H-7'), 7.75 (dt, ³J = 7.8, ⁴J = 1.8, 1 H, H-5'), 7.79 (dt,

$^3J = 7.8$, $^4J = 1.8$, 1 H, H-6'), 8.03 (d, $^3J = 7.8$, 1 H, H-4') ppm. ^{13}C NMR (75.6 MHz, $[\text{D}_6]\text{DMSO}$): $\delta = 12.2$ ($4 \times \text{CH}_3\text{CH}_2$), 44.8 ($4 \times \text{CH}_3\text{CH}_2$), 55.7 ($2 \times \text{CH}_3\text{O}$), 106.2 ($2 \times \text{CH}$), 108.8 (C), 109.0 (C), 109.1 ($2 \times \text{CH}$), 124.8 (C), 126.4 (CH), 130.0 ($2 \times \text{CH}$), 135.2 (CH), 142.7 (C), 145.9 (C), 146.0 (C), 148.4 ($4 \times \text{C}$), 151.4 (C), 168.4 (CO) ppm. ESI-MS, positive mode, m/z (rel. int., %): 503 (100) $[\text{M} + \text{H}]^+$, 1027 (6) $[2\text{M} + \text{Na}]^+$. HR-MS (ESI, positive mode): found: 503.2541, 525.2362; calcd. for $\text{C}_{30}\text{H}_{34}\text{N}_2\text{O}_5$: 503.2546 $[\text{M} + \text{H}]^+$, 525.2365 $[\text{M} + \text{Na}]^+$.

3-(*N,N*-Diethylamino)-6-methoxy-9-(3'-carboxyphenyl)xanthene (39-Me): Compound **37**

(1.6 g, 5.1 mmol), 3-methoxyphenol (**38-Me**) (0.74 g, 6.0 mmol) and 50% aq. sulphuric acid (25 mL) were placed into the flask equipped with a reflux condenser. The reaction mixture was heated at 125 °C for 12 h. After cooling to 0 °C, the mixture was neutralized with 4.6 M aq. NaOH (102 mL). After the separation

of the red oily product from the aqueous solution was complete (ca. 1 h), the aqueous solution was decanted, and the red oil dissolved in MeOH. The organic solution was dried and concentrated in vacuo. The residue was purified by chromatography on silica gel (200 g) with toluene / MeOH mixture (2:1) as an eluent, and the title compound was isolated as a red foam (0.96 g, 47%); decomp. > 300 °C. ^1H NMR (300 MHz, $[\text{D}_6]\text{DMSO}$): $\delta = 1.10$ (t, $^3J = 7.2$, 6 H), 3.36 (q, $^3J = 7.2$, 4 H), 3.80 (s, 3 H, OMe), 6.46 (m, 3 H, H-5,7,8), 6.62 (d, $^3J = 8.7$, 1 H, H-1), 6.68 (dd, $^3J = 8.7$, $^4J = 2.4$, 1 H, H-2), 6.88 (d, $^4J = 2.4$, 1 H, H-4), 7.26 (d, $^3J = 7.8$, 1 H, H-7'), 7.72 (dt, $^3J = 7.8$, $^4J = 1.8$, 1 H, H-5'), 7.77 (dt, $^3J = 7.8$, $^4J = 1.8$, 1 H, H-6'), 7.98 (d, $^3J = 7.8$, 1 H, H-4') ppm. ^{13}C NMR (75.6 MHz, $[\text{D}_6]\text{DMSO}$): $\delta = 12.2$ ($2 \times \text{CH}_3\text{CH}_2$), 43.7 ($2 \times \text{CH}_3\text{CH}_2$), 55.5 (CH_3O), 83.5 (C), 96.9 (CH), 100.8 (CH), 104.6 (C), 108.6 (CH), 111.3 (CH), 111.4 (C), 123.9 (CH), 124.4 (CH), 126.3 (C), 128.5 (CH), 128.8 (CH), 129.9 (CH), 135.4 (CH), 149.2 (C), 152.13 (C), 152.17 (C), 152.3 (C), 160.9 (C), 168.7 (CO) ppm. ESI-MS, positive mode, m/z (rel. int., %): 402 (55) $[\text{M} + \text{H}]^+$, 424 (100) $[\text{M} + \text{Na}]^+$, 825 (32) $[2\text{M} + \text{Na}]^+$, 1226 (41) $[3\text{M} + \text{Na}]^+$. HR-MS (ESI, positive mode): found: 402.1702, 424.1519; calcd. for $\text{C}_{25}\text{H}_{23}\text{NO}_4$: 402.1705 $[\text{M} + \text{H}]^+$, 424.1525 $[\text{M} + \text{Na}]^+$.

Spiroamide 40-Me: Compound **39-Me** (0.20 g, 0.50 mmol) was suspended in dry 1,2-

dichloroethane (5 mL) and POCl_3 (138 μL , 1.5 mmol) was added. The mixture was heated at reflux under Ar for 4 h. All volatile materials were evaporated in vacuo into a trap cooled with dry ice, and the residue was flushed with argon. The

resulted shiny red foam (compound **41-Me**) was used in further operations without additional purification.

Dry acetonitrile (10 mL) was added to the flask, followed by aniline (46 μ L, $d = 1.02$, 0.50 mmol) and triethylamine (0.21 mL, $d = 0.73$, 1.5 mmol). The reaction mixture was refluxed overnight, and the solvent was evaporated in vacuo. The residue was dissolved in CHCl_3 (20 mL), and the organic solution was washed with water and saturated aqueous NaHCO_3 (20 mL each) and dried. The residue was purified by chromatography on silica gel (50 g) with CH_2Cl_2 / MeOH mixture (20:1) as an eluent, and the title compound was isolated as a pink solid (210 mg, 88%); decomp. $> 300^\circ\text{C}$. ^1H NMR (300 MHz): $\delta = 1.12$ (t, $^3J = 7.5$, 6 H), 3.28 (q, $^3J = 7.5$, 4 H), 3.73 (s, 3 H, OMe), 6.22 (d, $^3J = 9.0$, 1 H, H-8), 6.31 (dd, $^3J = 9.0$, $^4J = 2.4$, 1 H, H-7), 6.51 (m, 2 H, H-4,5), 6.59 (d, $^3J = 8.7$, 1 H, H-1), 6.64 (m, 2 H, H-2'',6''), 6.69 (dd, $^3J = 8.7$, $^4J = 2.0$, 1 H, H-2), 7.08 (m, 4 H, H-7'+H-3'',4'',5''), 7.49 (m, 2 H, H-5'/6'), 7.98 (m, 1 H, H-4') ppm. ^{13}C NMR (125.7 MHz): $\delta = 12.4$ ($2\times\text{CH}_3\text{CH}_2$), 44.3 ($2\times\text{CH}_3\text{CH}_2$), 55.3 (CH_3O), 67.3 (C), 97.7 (CH), 100.6 (CH), 105.7 (C), 108.5 (CH), 110.9 (CH), 112.0 (C), 123.5 (CH), 123.9 (CH), 127.0 (CH), 127.5 ($2\times\text{CH}$), 128.5 (CH), 128.6 ($2\times\text{CH}$), 128.8 (CH), 129.1 (CH), 130.9 (C), 133.0 (CH), 136.0 (C), 148.9 (C), 152.7 (C), 152.8 (C), 152.9 (C), 160.3 (C), 167.7 (CO) ppm. ESI-MS, positive mode, m/z (rel. int., %): 499 (6) $[\text{M} + \text{Na}]^+$, 975 (100) $[2\text{M} + \text{Na}]^+$, 1451 (55) $[3\text{M} + \text{Na}]^+$. HR-MS (ESI, positive mode): found: 477.2164; calcd. for $\text{C}_{31}\text{H}_{28}\text{N}_2\text{O}_3$: 477.2178 $[\text{M} + \text{H}]^+$.

Spiroamide 40-H: A solution of BBR_3 (60 μ L, 0.63 mmol) in CH_2Cl_2 (5 mL) was cooled to -20°C , and the solution of compound **40-Me** (0.10 g, 0.21 mmol) in CH_2Cl_2 (5 mL) was added dropwise. The mixture was stirred at -20°C for 30 min, and then at the room temperature overnight.

The reaction mixture was diluted with CH_2Cl_2 (10 mL) and water (5 mL) was added carefully to it. The organic solution was washed with saturated aqueous NaHCO_3 (20 mL) and dried. The residue after evaporation of the solvent was purified by chromatography on silica gel (40 g) with CH_2Cl_2 / MeOH mixture (20:1) as an eluent, and the title compound was isolated as a pink solid (60 mg, 62%); decomp. $> 290^\circ\text{C}$. ^1H NMR (300 MHz, $[\text{D}_6]\text{DMSO}$): $\delta = 1.06$ (t, $^3J = 7.5$, 6 H), 3.32 (q, $^3J = 7.5$, 4 H), 6.28 (d, $^4J = 2.4$, 1 H, H-5), 6.41 (dd, $^3J = 9.0$, $^4J = 2.4$, 1 H, H-7), 6.47 (m, 2 H, H-1,2), 6.59 (m, 2 H, H-4,8), 6.75 (m, 2 H, H-2'',6''), 7.13 (m, 4 H, H-7'+H-3'',4'',5''), 7.57 (m, 2 H, H-5'/6'), 7.88 (m, 1 H, H-4'), 9.78 (s, 1 H, OH) ppm. ^{13}C NMR (75.6 MHz, $[\text{D}_6]\text{DMSO}$): $\delta = 12.3$ ($2\times\text{CH}_3\text{CH}_2$), 43.5 ($2\times\text{CH}_3\text{CH}_2$), 66.2 (C), 97.1 (CH), 102.1 (CH), 105.2 (C), 108.4 (CH), 110.2 (CH), 112.1 (C),

122.8 (CH), 123.7 (CH), 126.35 (2×CH), 126.4 (CH), 128.4 (2×CH), 128.5 (CH), 128.8 (CH), 129.7 (CH), 133.3 (CH), 136.6 (C), 148.4 (C), 151.94 (C), 151.96 (C), 153.0 (C), 158.2 (C), 166.5 (CO) ppm. ESI-MS, negative mode, m/z (rel. int., %): 461 (100) $[M - H]^-$, 923 (95) $[2M - H]^-$, positive mode, m/z (rel. int., %): 485 (10) $[M + Na]^+$, 947 (100) $[2M + Na]^+$, 1409 (8) $[3M + Na]^+$. HR-MS (ESI, negative mode): found: 461.1871, calcd. for $C_{30}H_{26}N_2O_3$: 461.1865 $[M - H]^-$.

Adduct 51: A solution of 4-nitro-2-aminophenol (**49**) (3.1 g, 20 mmol) in dry DMF (30 mL)

was prepared in the Schlenk-flask equipped with a septum and flushed with argon. Sodium carbonate (4.2 g, 40 mmol) was added to the flask, the mixture was vigorously stirred, and then 1,11-dichloro-3,6,9-trioxaundecane **50** (3.9 mL, $d = 1.18$, 20 mmol) was

added. After heating at 90 °C for 12 hours, an additional portion of Na_2CO_3 (2.1 g, 20 mmol) was added, and after heating for 6 h, another portion of Na_2CO_3 (2.1 g, 20 mmol) was added. After heating at 90 °C for 6 h, the mixture was cooled. The solvent was evaporated in vacuo, and the residue was diluted with $CHCl_3$ (200 mL). The organic solution was washed with 1 M aq. NaOH (3×200 mL), filtered through the cottonwool, and the solvent was removed in vacuo. The residue was purified by chromatography on SiO_2 (300 g) with CH_2Cl_2 / MeOH mixture (100:1) as an eluent, and the title compound was isolated as a yellow solid (0.39 g, 6.2%). HPLC: 70/30 → 0/100 (A/B) in 25 min, 1 mL/min, 25 °C, $t_R = 12.8$ min, detection at 254 nm. 1H NMR (300 MHz): $\delta = 3.28$ (q, $^3J = 5.4$, 2 H), 3.66 (m, 6 H), 3.73 (m, 2 H), 3.78 (m, 2 H), 3.88 (m, 2 H), 4.17 (m, 2 H), 5.36 (m, 1 H, NH), 6.68 (d, $^3J = 9.0$, 1 H), 7.34 (d, $^4J = 2.7$, 1 H), 7.58 (dd, $^3J = 9.0$, $^4J = 2.7$, 1 H) ppm. ^{13}C NMR (75.6 MHz): $\delta = 42.9$ (CH_2N), 67.9 (CH_2OAr), 68.3 (CH_2), 68.8 (CH_2), 69.8 (CH_2), 70.0 (2× CH_2), 70.4 (CH_2), 104.0 (CH), 109.0 (CH), 113.2 (CH), 139.4 (C), 142.5 (C), 151.2 (C) ppm. ESI-MS, positive mode, m/z (rel. int., %): 313 (18) $[M + H]^+$, 335 (100) $[M + Na]^+$.

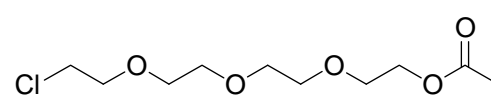

Compound 48a: According to the GP2, adduct **51** (0.390 g, 1.3 mmol) was reduced in EtOAc

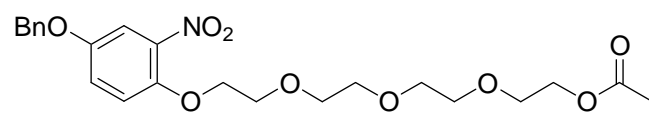

and gave the title compound as a brown oil (0.35 g, 98%). HPLC: 80/20 → 50/50 (A/B) in 25 min, 1 mL/min, 25 °C, $t_R = 2.8$ min, detection at 254 nm. 1H NMR (300 MHz): $\delta = 3.18$ (m, 2 H), 3.66 (m, 11 H, 4× CH_2 + NH + NH_2), 3.75 (m, 4 H, 2× CH_2), 3.99 (m, 2 H), 5.94 (dd, $^3J = 8.1$, $^4J = 2.4$, 1 H), 5.98 (d, $^4J = 2.4$, 1 H), 6.60 (d, $^3J = 9.0$, 1 H) ppm. ^{13}C NMR (75.6 MHz): $\delta = 43.1$ (CH_2N), 69.2 (CH_2OAr), 69.7 (CH_2), 69.8 (2× CH_2), 69.9 (CH_2),

70.0 (CH₂), 70.4 (CH₂), 99.0 (CH), 102.3 (CH), 114.9 (CH), 139.7 (C), 140.8 (C), 141.6 (C) ppm. ESI-MS, positive mode, *m/z* (rel. int., %): 283 (25) [M + H]⁺, 305 (100) [M + Na]⁺. HR-MS (ESI, positive mode): found: 283.1652; calcd. for C₁₄H₂₂N₂O₄: 283.1658 [M + H]⁺.

2-[2-[2-(2-Chloroethoxy)-ethoxy]-ethoxy]-ethyl acetate (54-Ac): A solution of alcohol **53**

 (4.0 g, 19 mmol) in dry AcOH (15 mL) was prepared in the flask equipped with a reflux condenser, and acetic anhydride (1.87 mL, *d* = 1.08, 20 mmol) with 3 drops of pyridine were added. The reaction mixture was refluxed for 26 hours. All volatile materials were evaporated in vacuo, and the residue was diluted with CHCl₃ (50 mL). The organic solution was washed with 5% aq. NaHCO₃ (50 mL), 1 M aq. HCl (2×50 mL), brine (50 mL) and dried. The solvent was removed in vacuo, the title compound was isolated as a colourless liquid (4.10 g, 86%). ¹H NMR (300 MHz): δ = 2.04 (s, 3 H), 3.66 (m, 14 H), 4.18 (m, 2 H) ppm. ¹³C NMR (75.5 MHz): δ = 20.9 (CH₃), 42.7 (CH₂Cl), 63.6 (CH₂OAc), 69.1 (CH₂), 70.5 (CH₂), 70.57 (CH₂), 70.60 (CH₂), 70.62 (CH₂), 71.3 (CH₂), 171.0 (CO) ppm. CI-MS (NH₃), positive mode, *m/z* (rel. int., %): 272 (100) [M + NH₄]⁺, 274 (32) [M + NH₄]⁺. HR-MS (ESI, positive mode): found: 277.0816; calcd. for C₁₀H₁₉ClO₅: 277.0819 [M + Na]⁺.

2-[2-[2-(2-(4-Benzyloxy-2-nitrophenyloxy)ethoxy)-ethoxy]-ethoxy]-ethyl acetate (59): In a

 dry Schlenk-flask equipped with a septum and flushed with nitrogen, compound **58** (2.8 g, 11 mmol) was dissolved in DMF (30 mL) and cooled to 0 °C. Then *t*-BuOK (1.3 g, 11 mmol) was added in small portions, and the mixture was stirred for 30 min at 0 °C, until the clear red solution was obtained. After that, KI (0.19 g, 1.1 mmol) and compound **54-Ac** (3.0 g, 12 mmol) were added to it, and the reaction mixture was heated at 90 °C for 3 days. All volatile materials were evaporated in vacuo, and the residue was diluted with CHCl₃ (80 mL). The organic solution was washed with saturated aq. Na₂CO₃ (2×100 mL), brine (100 mL) and dried. The solvent was removed in vacuo, the residue was purified by chromatography on silica gel (100 g) with *n*-hexane / EtOAc mixture (4:1 → 0:1) as an eluent, and the title compound was isolated as a yellow liquid (4.30 g, 82%). HPLC: 50/50 → 0/100 (A/B) in 25 min, 1 mL/min, 25 °C, *t*_R = 10.3 min, detection at 254 nm. ¹H NMR (300 MHz): δ = 2.04 (s, 3 H), 3.70 (m, 10 H), 3.84 (m, 2 H), 4.18 (m, 4 H), 5.03 (s, 2 H, CH₂Ph), 7.04 (d, ³*J* = 9.0, 1 H), 7.12 (dd, ³*J* = 9.0, ⁴*J* = 3.0, 1 H), 7.36 (m, 5 H, CH₂Ph), 7.42 (d, ⁴*J* = 3.0, 1 H) ppm. ¹³C NMR (75.5 MHz): δ = 20.9 (CH₃),

63.6 (CH_2OAc), 69.1 (CH_2), 69.4 (CH_2), 70.48 (CH_2), 70.51 ($2\times\text{CH}_2$), 70.6 (CH_2), 70.9 (CH_2), 71.0 (CH_2Ph), 111.0 (CH), 117.2 (CH), 121.5 (CH), 127.5 ($2\times\text{CH}$), 128.3 (CH), 128.7 ($2\times\text{CH}$), 135.9 (C), 140.1 (C), 146.7 (C), 152.2 (C), 171.0 (CO) ppm. ESI-MS, positive mode, m/z (rel. int., %): 486 (100) $[\text{M} + \text{Na}]^+$. HR-MS (ESI, positive mode): found: 481.2180, 486.1735; calcd. for $\text{C}_{23}\text{H}_{29}\text{NO}_9$: 481.2186 $[\text{M} + \text{NH}_4]^+$, and 486.1740 $[\text{M} + \text{Na}]^+$.

2-{2-[2-(2-(4-Benzyloxy-2-aminophenyl)ethoxy)-ethoxy]-ethoxy}-ethanol (60a): Into a

dry three-necked flask equipped with a septum, dropping funnel and a reflux condenser with nitrogen inlet and outlet (on the top), compound **59** (4.7 g, 10 mmol), MeOH (50 mL) and Raney-Ni (ca. 2.0 g, slurry in MeOH) were loaded under nitrogen. The reaction mixture was warmed-up to 60 °C (bath), and a solution of $\text{N}_2\text{H}_4\cdot\text{H}_2\text{O}$ (2.0 mL, $d = 1.01$, 40.0 mmol) in 40 mL of MeOH was added dropwise with stirring at reflux during 1.5 hours. Then the reaction mixture was refluxed for 2 hours, cooled to room temperature and filtered through Celite[®]. The filter-cake was washed with MeOH (3×50 mL), and the solvents were removed in vacuo. Then the residue was heated in high vacuo (0.5 torr) at 60 °C for 1 hour. The product was isolated as a violet-brown oil which easily oxidized in air (3.78 g, 95%). ^1H NMR (300 MHz): $\delta = 3.58$ (m, 2 H), 3.67 (m, 10 H), 3.76 (m, 2 H), 4.17 (m, 2 H), 4.95 (s, 2 H, CH_2Ph), 6.25 (dd, $^3J = 8.7$, $^4J = 3.0$, 1 H), 6.38 (d, $^4J = 3.0$, 1 H), 6.72 (d, $^3J = 8.7$, 1 H), 7.35 (m, 5 H, CH_2Ph) ppm. ^{13}C NMR (75.5 MHz): $\delta = 61.7$ (CH_2OH), 69.8 (CH_2), 69.9 (CH_2), 70.4 (CH_2), 70.58 (CH_2), 70.63 ($2\times\text{CH}_2$), 72.6 (CH_2), 72.8 (CH_2Ph), 103.1 (CH), 103.5 (CH), 115.3 (CH), 127.4 ($2\times\text{CH}$), 127.7 (CH), 128.5 ($2\times\text{CH}$), 137.6 (C), 138.8 (C), 141.0 (C), 154.5 (C) ppm. ESI-MS, positive mode, m/z (rel. int., %): 414 (100) $[\text{M} + \text{Na}]^+$. HR-MS (ESI, positive mode): found: 392.2068; calcd. for $\text{C}_{21}\text{H}_{29}\text{NO}_6$: 392.2073 $[\text{M} + \text{H}]^+$.

2-[2-[2-(2-(4-Benzyloxy-2-aminophenyl)ethoxy)-ethoxy]-ethoxy]-ethyl tosylate (60b):

In the flask (No. 1) equipped with a reflux condenser, sodium (0.15 mg, 6.5 mmol) was dissolved in *i*-PrOH (5 mL) with heating at 90 °C. Then this solution was cooled to room temperature, and DMSO (5 mL) was added. In the dry flask (No. 2), compound **60a** (0.50 mg, 1.3 mmol) was added to the solution from the flask 1 (2 mL), the reaction mixture was stirred for 15 min at the room temperature, and tosyl chloride (0.24 g, 1.3 mmol) was added in small portions. After stirring for 2 hours, the

reaction mixture was diluted with CHCl_3 (10 mL). The organic solution was washed with water (2×20 mL) and dried. The solvent was removed in vacuo, the residue was purified by chromatography on silica gel (100 g) with *n*-hexane / EtOAc mixture (4:1 \rightarrow 0:1) as an eluent, and the title compound was isolated as a brown oil (0.11 g, 16%). HPLC: 50/50 \rightarrow 0/100 (A/B) in 25 min, 1 mL/min, 25 °C, t_R = 12.7 min, detection at 254 nm. ^1H NMR (300 MHz): δ = 2.21 (s, 3 H), 3.65 (m, 10 H), 3.75 (m, 2 H), 4.06 (m, 2 H), 4.14 (m, 2 H), 4.94 (s, 2 H, CH_2Ph), 6.28 (dd, 3J = 8.7, 4J = 2.7, 1 H), 6.42 (d, 4J = 2.7, 1 H), 6.72 (d, 3J = 8.7, 1 H), 7.33 (m, 7 H, CH_2Ph + CH_{Ts} + CH_{Ts}), 7.76 (d, 3J = 8.1, 2 H) ppm. ^{13}C NMR (75.5 MHz): δ = 21.6 (CH_3), 68.7 (CH_2OTs), 69.2 (CH_2), 69.7 (CH_2), 69.8 (CH_2), 70.3 (CH_2), 70.46 (CH_2), 70.55 (CH_2), 70.58 (CH_2), 70.7 (CH_2Ph), 103.3 (CH), 104.0 (CH), 115.2 (CH), 127.5 ($2 \times \text{CH}$), 127.8 (CH), 128.0 ($2 \times \text{CH}$), 128.5 ($2 \times \text{CH}$), 129.8 ($2 \times \text{CH}$), 132.9 (C), 137.4 (C), 137.7 (C), 141.1 (C), 144.8 (C), 154.4 (C) ppm. ESI-MS, positive mode, m/z (rel. int., %): 546 (100) [$\text{M} + \text{H}$] $^+$.

2-[2-[2-(2-(4-Benzyloxy-2-(*N*-tosylamino)phenyloxy)ethoxy)-ethoxy]-ethoxy]-ethyl

tosylate (61): According to the GP3, compound **60a** (3.9 g, 9.9 mmol) and tosyl chloride (3.8 g, 20 mmol) gave, after

purification by chromatography on silica gel (400 g) with CH_2Cl_2 / MeOH mixture (50:1) as an eluent, the title compound as a brown oil (5.21 g, 75%). ^1H NMR (300 MHz): δ = 2.22 (s, 3 H), 2.41 (s, 3 H), 3.65 (m, 12 H), 3.84 (m, 2 H), 4.13 (m, 2 H), 4.98 (s, 2 H, CH_2Ph), 6.55 (dd, 3J = 8.7, 4J = 2.7, 1 H), 6.72 (d, 4J = 2.7, 1 H), 7.12 (d, 3J = 8.1, 2 H_{TsNH}), 7.24 (d, 3J = 8.7, 1 H), 7.30 (d, 3J = 8.4, 2 H_{TsO}), 7.36 (m, 5 H, CH_2Ph), 7.59 (d, 3J = 8.1, 2 H_{TsNH}), 7.76 (d, 3J = 8.4, 2 H_{TsO}) ppm. ^{13}C NMR (75.5 MHz): δ = 21.5 (CH_3), 21.6 (CH_3), 68.7 (CH_2OTs), 69.2 (CH_2), 69.5 (CH_2), 70.5 (CH_2), 70.61 (CH_2), 70.64 (CH_2), 70.7 (CH_2), 70.8 (CH_2Ph), 71.0 (CH_2), 107.4 (CH), 111.3 (CH), 116.7 (CH), 127.3 ($2 \times \text{CH}$), 127.5 ($2 \times \text{CH}$), 127.90 (CH), 127.94 ($2 \times \text{CH}$), 128.5 ($2 \times \text{CH}$), 129.4 ($2 \times \text{CH}$), 129.8 ($2 \times \text{CH}$), 136.5 (C), 137.0 (C), 142.7 (C), 143.5 (C), 144.7 (C), 154.1 (C) ppm. ESI-MS, negative mode, m/z (rel. int., %): 698 (100) [$\text{M} - \text{H}$] $^-$, positive mode, m/z (rel. int., %): 722 (100) [$\text{M} + \text{Na}$] $^+$. HR-MS (ESI, positive mode): found: 717.2510, and 722.2066; calcd. for $\text{C}_{35}\text{H}_{41}\text{NO}_{10}\text{S}_2$: 717.2516 [$\text{M} + \text{NH}_4$] $^+$, and 722.2070 [$\text{M} + \text{Na}$] $^+$.

Crown ether 62: According to the GP4, compound **61** (6.4 g, 9.2 mmol) and Cs_2CO_3 (3.3 g, 10 mmol) in DMF (40 mL) gave, after purification by chromatography on silica gel (400 g)

with CH_2Cl_2 / MeOH mixture (100:1) as an eluent, the title compound as a light brown oil (2.61 g, 54%). HPLC: 50/50 \rightarrow 0/100 (A/B) in 25 min, 1 mL/min, 25 $^\circ\text{C}$, t_R = 14.9 min, detection at 254 nm. ^1H NMR (300 MHz): δ = 2.38 (s, 3 H), 3.63 (m, 16 H), 4.94 (s, 2 H, $\underline{\text{CH}_2\text{Ph}}$), 6.63 (d, 3J = 8.7, 1 H), 6.86 (m, 2 H), 7.20 (d, 3J = 8.1, 2 H_{TsN}), 7.35 (m, 5 H, $\underline{\text{CH}_2\text{Ph}}$), 7.59 (d, 3J = 8.1, 2 H_{TsNH}) ppm. ^{13}C NMR (75.5 MHz): δ = 21.5 (CH_3), 50.3 (CH_2), 66.8 (CH_2), 68.9 (CH_2), 69.8 (CH_2), 70.1 (CH_2), 70.6 (CH_2), 70.7 (CH_2), 70.8 ($\underline{\text{CH}_2\text{Ph}}$), 71.3 (CH_2), 112.3 (CH), 116.0 (CH), 119.1 (CH), 127.6 ($2\times\text{CH}$), 127.91 ($2\times\text{CH}$), 127.96 (CH), 128.2 (C), 128.5 ($2\times\text{CH}$), 128.9 ($2\times\text{CH}$), 136.8 (C), 137.1 (C), 142.7 (C), 150.0 (C), 152.1 (C) ppm. ESI-MS, negative mode, m/z (rel. int., %): 544 (45) $[\text{M} + \text{OH}]^-$, 562 (80) $[\text{M} + \text{Cl}]^-$, 1089 (100) $[2\text{M} + \text{Cl}]^-$, positive mode, m/z (rel. int., %): 550 (100) $[\text{M} + \text{Na}]^+$. HR-MS (ESI, positive mode): found: 528.2049, 545.2313, 550.1869, and 566.1608; calcd. for $\text{C}_{28}\text{H}_{33}\text{NO}_7\text{S}$: 528.2056 $[\text{M} + \text{H}]^+$, 545.2321 $[\text{M} + \text{NH}_4]^+$, 550.1875 $[\text{M} + \text{Na}]^+$, and 566.1615 $[\text{M} + \text{K}]^+$.

Crown ether 63a: *Method 1:* According to the GP4, compound **60b** (0.10 g, 0.18 mmol) and

caesium carbonate (63 mg, 0.19 mmol) in DMF (2 mL) gave, after purification by chromatography on silica gel (25 g) with CH_2Cl_2 / MeOH mixture (100:1) as an eluent, the title compound as a slightly brown oil (20 mg, 29%).

Method 2: In a dry flask (No. 1) equipped with a septum, sodium (1.5 g, 65 mmol) was dissolved in the solution of naphthalene (11 g, 86 mmol) in DME (50 mL) with stirring for 2 h at room temperature. In a dry flask (No. 2) equipped with a septum, to a solution of compound **62** (0.94 g, 1.8 mmol) in DME (20 mL), the dark green solution (from the flask 1) was added dropwise at -78 $^\circ\text{C}$, until the stable green color was persisted. Then the saturated solution of NaHCO_3 (10 mL) was added to the reaction mixture, and it was warmed-up to room temperature. Dry K_2CO_3 (7.0 g) was added, and the mixture was stirred overnight. Then it was filtered, the filter-cake was washed with diethyl ether (3×40 mL), and the solvents were removed in vacuo. The residue was purified by chromatography on silica gel (100 g) with *n*-hexane / EtOAc mixture (1:1) as an eluent, and the title compound was isolated as slightly brown oil (410 mg, 62%). HPLC: 50/50 \rightarrow 0/100 (A/B) in 25 min, 1 mL/min, 25 $^\circ\text{C}$, t_R = 6.8 min, detection at 254 nm. ^1H NMR (300 MHz): δ = 3.20 (m, 2 H), 3.66 (m, 8 H), 3.77 (m, 4 H), 4.14 (m, 2 H), 4.96 (s, 2 H, $\underline{\text{CH}_2\text{Ph}}$), 5.16 (br s, 1 H), 6.16 (dd, 3J = 8.7, 4J = 2.7, 1 H), 6.25 (d, 4J = 2.7, 1 H), 6.67 (d, 3J = 8.7, 1 H), 7.35 (m, 5 H, $\underline{\text{CH}_2\text{Ph}}$) ppm. ^{13}C NMR (75.5

MHz): δ = 43.1 (CH₂N), 69.0 (CH₂), 69.5 (CH₂), 69.7 (CH₂), 69.8 (CH₂), 69.9 (CH₂), 70.0 (CH₂), 70.3 (CH₂), 70.4 (CH₂Ph), 99.2 (CH), 100.0 (CH), 113.5 (CH), 127.6 (2×CH), 127.7 (CH), 128.5 (2×CH), 137.5 (C), 140.8 (C), 141.1 (C), 154.7 (C) ppm. ESI-MS, positive mode, m/z (rel. int., %): 396 (100) [M + Na]⁺, 768 (24) [2M + Na]⁺. HR-MS (ESI, positive mode): found: 374.1961, and 396.1781; calcd. for C₂₁H₂₇NO₅: 374.1967 [M + H]⁺, and 396.1787 [M + Na]⁺.

Acetanilide 63b: In a flask equipped with a reflux condenser, compound **63a** (0.12 mg, 0.32

mmol) was dissolved in AcOH (7 mL). To this solution, acetic anhydride (45.3 μ L, d = 1.08, 0.48 mmol) was added dropwise. The reaction mixture was refluxed overnight, cooled to room temperature, and poured into the cold water. The aqueous

suspension was extracted with CH₂Cl₂ (3×10 mL). All volatile materials were evaporated in vacuo. The obtained oil was diluted with CH₂Cl₂ and the solvent was evaporated once more. The latter operation was repeated two times. The title compound was isolated as a very light brown oil (132 mg, 99%). ¹H NMR (300 MHz): δ = 1.75 (s, 3 H, CH₃), 3.14 (m, 1 H), 3.62 (m, 8 H), 3.78 (m, 4 H), 4.02 (m, 1 H), 4.16 (m, 1 H), 4.22 (m, 1 H), 4.98 (s, 2 H, CH₂Ph), 6.75 (d, ⁴ J = 3.0, 1 H), 6.80 (d, ³ J = 9.0, 1 H), 6.87 (dd, ³ J = 9.0, ⁴ J = 3.0, 1 H), 7.35 (m, 5 H, CH₂Ph) ppm. ¹³C NMR (75.5 MHz): δ = 21.9 (CH₃), 49.1 (CH₂N), 67.6 (CH₂), 68.0 (CH₂), 69.1 (CH₂), 70.07 (CH₂), 70.14 (CH₂), 70.19 (CH₂), 70.8 (CH₂Ph), 71.7 (CH₂), 112.7 (CH), 115.1 (CH), 116.4 (CH), 127.5 (2×CH), 128.1 (CH), 128.6 (2×CH), 132.5 (C), 136.6 (C), 149.1 (C), 152.7 (C), 171.3 (CO) ppm. ESI-MS, positive mode, m/z (rel. int., %): 438 (100) [M + Na]⁺, 853 (100) [2M + Na]⁺. HR-MS (ESI, positive mode): found: 438.1887; calcd. for C₂₃H₂₉NO₆: 438.1893 [M + Na]⁺.

N-ethyl crown ether 63c: A solution of BH₃ in THF (1 M; 0.5 mL) at 0 °C, was added to

compound **63b** (0.13 mg, 0.32 mmol) in dry THF (3 mL), and the mixture was heated at reflux overnight. Then it was cooled to 0 °C, an excess of BH₃ was carefully destroyed by adding MeOH (1 mL), and water (1 mL) was added. After stirring at room temperature for

20 min, the mixture was diluted with Et₂O (20 mL) and the organic layer was separated. The aqueous layer was extracted with Et₂O (3×10 mL), then the combined organic layers were washed with saturated aqueous NaHCO₃ (40 mL) and brine (40 mL). The organic solution was filtered through a piece of cottonwool, and the solvent was removed in vacuo. The title

compound was isolated as a light brown oil (0.127 mg, 99%). ^1H NMR (300 MHz): δ = 1.06 (t, 3J = 7.2, 3 H), 3.18 (q, 3J = 7.2, 2 H), 3.26 (m, 2 H), 3.66 (m, 8 H), 3.75 (m, 2 H), 3.88 (m, 2 H), 4.09 (m, 2 H), 4.97 (s, 2 H, CH_2Ph), 6.44 (dd, 3J = 8.7, 4J = 2.7, 1 H), 6.56 (d, 4J = 2.7, 1 H), 6.69 (d, 3J = 8.7, 1 H), 7.36 (m, 5 H, CH_2Ph) ppm. ^{13}C NMR (125.7 MHz): δ = 12.7 (CH_3CH_2), 46.3 (CH_3CH_2), 53.0 (CH_2N), 68.5 (CH_2), 69.0 (CH_2), 69.97 (CH_2), 69.99 (CH_2), 70.4 (CH_2), 70.5 ($2\times\text{CH}_2$), 70.6 (CH_2), 105.4 (CH), 108.2 (CH), 113.3 (CH), 127.5 ($2\times\text{CH}$), 127.8 (CH), 128.4 ($2\times\text{CH}$), 137.3 (C), 141.4 (C), 146.7 (C), 153.1 (C), ppm. ESI-MS, positive mode, m/z (rel. int., %): 424 (100) $[\text{M} + \text{Na}]^+$. HR-MS (ESI, positive mode): found: 402.2280; calcd. for $\text{C}_{23}\text{H}_{31}\text{NO}_5$: 402.2280 $[\text{M} + \text{H}]^+$.

Crown ether 63d: To a solution of crown ether **63a** (0.12 mg, 0.32 mmol) in dry MeCN (2 mL) in a dry Schlenk-flask equipped with a septum and flushed with argon, DIPEA (62 μL , d = 0.76, 0.36 mmol) and methyl 2-bromoacetate (32 μL , d = 1.62, 0.34 mmol) were added at room temperature. The reaction mixture was heated at 100 $^\circ\text{C}$ (bath temperature) for 1 day. All volatile materials were evaporated in

vacuo. The residue was purified by chromatography on silica gel (20 g) with CH_2Cl_2 / MeOH mixture (30:1 \rightarrow 10:1) as an eluent, and the title compound was isolated as slightly brown oil (0.11 g, 73%). ^1H NMR (300 MHz): δ = 3.46 (m, 2 H), 3.59 (m, 2 H), 3.68 (m, 11 H, $4\times\text{CH}_2 + \text{CH}_3$), 3.85 (m, 2 H), 4.07 (m, 2 H), 4.15 (s, 2 H, CH_2), 4.95 (s, 2 H, CH_2Ph), 6.46 (dd, 3J = 8.7, 4J = 2.7, 1 H), 6.59 (d, 4J = 2.7, 1 H), 6.72 (d, 3J = 8.7, 1 H), 7.35 (m, 5 H, CH_2Ph) ppm. ^{13}C NMR (125.7 MHz): δ = 51.5 (CH_2COOMe), 52.0 (CH_2COOMe), 53.4 (CH_2N), 69.1 (CH_2), 69.6 (CH_2), 70.0 (CH_2), 70.2 (CH_2), 70.5 (CH_2), 70.7 (CH_2), 70.8 (CH_2Ph), 70.9 (CH_2), 106.5 (CH), 108.6 (CH), 114.9 (CH), 127.5 ($2\times\text{CH}$), 127.8 (CH), 128.4 ($2\times\text{CH}$), 137.3 (C), 141.0 (C), 146.1 (C), 153.4 (C), 172.1 (CH_2COOMe) ppm. ESI-MS, positive mode, m/z (rel. int., %): 468 (100) $[\text{M} + \text{Na}]^+$. HR-MS (ESI, positive mode): found: 446.2176; calcd. for $\text{C}_{24}\text{H}_{31}\text{NO}_7$: 446.2179 $[\text{M} + \text{H}]^+$.

Phenol 42a: According to the GP5, compound **63a** (60 mg, 0.16 mmol) with 10% Pd/C (12 mg) in AcOH (3 mL) gave the title compound as a brown oil which

solidified at -10 $^\circ\text{C}$ in ca. one week; yield (44 mg, 98%). ^1H NMR (300 MHz): δ = 3.14 (m, 2 H), 3.68 (m, 10 H), 3.77 (m, 2 H), 3.99 (m, 2 H), 5.30 (br s, 2 H, OH + NH), 6.04 (m, 1 H), 6.10 (m, 1 H), 6.58 (d, 3J = 8.7, 1 H) ppm. ^{13}C NMR (125.7 MHz): δ = 43.3 (CH_2N), 69.0 (CH_2), 69.6 (CH_2),

69.7 (2×CH₂), 69.8 (CH₂), 70.0 (CH₂), 70.3 (CH₂), 99.0 (CH), 101.8 (CH), 114.1 (CH), 140.4 (C), 140.7 (C), 151.4 (C) ppm. ESI-MS, negative mode, m/z (rel. int., %): 282 (100) [M – H][–], 565 (100) [2M – H][–], positive mode, m/z (rel. int., %): 306 (100) [M + Na]⁺, 589 (60) [2M + Na]⁺. HR-MS (ESI, negative mode): found: 282.1347; calcd. for C₁₄H₂₁NO₅: 282.1341 [M – H][–].

Phenol 42c: According to the GP5, compound **63d** (72 mg, 0.16 mmol) with 10% Pd/C (15 mg) in MeOH (3 mL) gave the title compound as a brownish oil,

yield (56 mg, 99%). ¹H NMR (300 MHz): δ = 3.45 (m, 2 H), 3.58 (m, 2 H), 3.68 (m, 11 H, 4×CH₂ + CH₃), 3.84 (m, 2 H), 4.06 (m, 2 H), 4.15 (s, 2 H), 6.35 (m, 1 H), 6.52 (m, 1 H), 6.64 (d, ³J = 8.7, 1 H) ppm. ¹³C NMR (75.5 MHz): δ = 51.5 (CH₂COOMe), 52.4 (CH₂COOMe), 53.7 (CH₂N), 67.9 (CH₂), 68.9 (CH₂), 69.5 (CH₂), 69.9 (CH₂), 70.2 (CH₂), 70.6 (CH₂), 70.7 (CH₂), 108.7 (2×CH), 115.5 (CH), 140.7 (CH), 145.7 (C), 150.6 (C), 172.2 (CH₂COOMe) ppm. ESI-MS, negative mode, m/z (rel. int., %): 354 (45) [M – H][–], 195 (100), positive mode, m/z (rel. int., %): 356 (20) [M + H]⁺, 378 (100) [M + Na]⁺. HR-MS (ESI, positive mode): found: 378.1529; calcd. for C₁₇H₂₅NO₇: 378.1523 [M + Na]⁺.

Phenol 68: Methyl ether **67** (0.18 g, 0.55 mmol) was suspended in dry 2,4,6-collidine (1 mL),

then LiI (0.29 g, 2.2 mmol) was added and the mixture was heated overnight in a closed thick-wall glass tube (bath temp. 180 °C). After cooling, the reaction mixture was transferred into the concentrated hydrochloric acid (2 mL). The resulted solution was cooled to 0 °C and neutralized with saturated aq. NaHCO₃. Then it was extracted

with CH₂Cl₂ (3×10 mL). The organic solution was filtered through a piece of cottonwool, and the solvent was removed in vacuo. The residue was purified by chromatography on silica gel (20 g) with *n*-hexane / EtOAc mixture (1:2 → 1:4) as an eluent, and the title compound was isolated as a brownish oil (77 mg, 45%). ¹H NMR (300 MHz): δ = 3.53 (m, 4 H), 3.63 (m, 12 H), 3.72 (m, 4 H), 6.13 (m, 2 H), 6.20 (m, 1 H), 7.02 (m, 1 H) ppm. ¹³C NMR (125.7 MHz): δ = 52.6 (2×CH₂N), 68.6 (2×CH₂), 70.2 (4×CH₂), 71.3 (2×CH₂), 98.6 (CH), 102.9 (CH), 104.1 (CH), 130.0 (CH), 149.1 (C), 156.9 (C) ppm. ESI-MS, negative mode, m/z (rel. int., %): 310 (100) [M – H][–], 621 (15) [2M – H][–], positive mode, m/z (rel. int., %): 334 (100) [M + Na]⁺. HR-MS (ESI) negative mode: found: 310.1660; calcd. for C₁₆H₂₅NO₅: 310.1654 [M – H][–], positive mode: found: 334.1627; calcd. for C₁₆H₂₅NO₅: 334.1630 [M + Na]⁺.

Indicator Ia: According to the GP1, benzophenone **69** (41 mg, 0.16 mmol), *p*-toluene sulfonic acid monohydrate (1.6 mg, 8.4 μ mol) and compound **42a** (30 mg, 0.11 mmol) were heated for 48 h and gave, after purification by chromatography on silica gel (20 g) with CH₂Cl₂ / MeOH mixture (10:1 \rightarrow 3:1) as an eluent, the title compound as a red-orange foam (5.9 mg, 11%).

HPLC: 70/30 \rightarrow 0/100 (A/B) in 25 min, 1 mL/min, 25 $^{\circ}$ C, t_R = 8.3 min, detection at 254 nm. ¹H NMR (300 MHz, CD₃OD): δ = 3.50 (m, 2 H, CH₂N), 3.66 (m, 8 H, 4 \times CH₂), 3.74 (m, 2 H), 3.78 (m, 2 H), 3.84 (m, 2 H), 3.88 (m, 1 H, CHH), 4.03 (m, 1 H, CHH), 6.50 (s, 1 H, H-5), 6.63 (m, 2 H, H-2/4), 6.80 (s, 1 H), 7.14 (m, 1 H, H-1), 7.23 (m, 1 H), 7.60 (m, 2 H), 8.05 (m, 1 H) ppm. ¹³C NMR (125.7 MHz, CD₃OD): δ = 43.6 (CH₂N), 68.8 (CH₂), 69.47 (CH₂), 69.53 (CH₂), 70.7 (CH₂), 70.90 (CH₂), 70.93 (2 \times CH₂), 95.5 (CH), 103.8 (CH), 108.3 (CH), 113.2 (C), 115.1 (C), 117.7 (CH), 124.3 (CH), 130.3 (CH), 130.4 (CH), 130.7 (CH), 132.1 (CH), 135.3 (C), 136.3 (C), 140.5 (C), 145.7 (C), 149.2 (C), 155.0 (C), 160.0 (C), 173.5 (CO) ppm. ESI-MS, negative mode, m/z (rel. int., %): 504 (100) [M – H][–]. HR-MS (ESI, negative mode): found: 504.1663; calcd. for C₂₈H₂₇NO₈: 504.1658 [M – H][–].

Indicator Ib: According to the GP5, compound **63c** (125 mg, 0.31 mmol) with 10% Pd/C (23 mg) in AcOH (2 mL) gave the compound **42b** as a brown oil (92 mg of crude product, 95%). According to the GP1, benzophenone **69** (62 mg, 0.24 mmol), *p*-toluene sulfonic acid monohydrate (2.0 mg, 11 μ mol) and compound **42b** (50 mg of crude product) were heated for 36 h and gave, after purification by chromatography on silica gel (20 g)

with CH₂Cl₂ / MeOH mixture (10:1 \rightarrow 4:1) as an eluent and preparative HPLC with reversed phase and gradient eluting with H₂O / MeCN mixture (2:8 \rightarrow 9:1, 40 min, 4 mL/min, , 25 $^{\circ}$ C, t_R = 14.5 min), the title compound as a red foam (4.8 mg, 5.8%). HPLC: 70/30 \rightarrow 0/100 (A/B) in 25 min, 1 mL/min, 25 $^{\circ}$ C, t_R = 7.2 min, detection at 254 nm. ¹H NMR (600 MHz, CD₃OD): δ = 1.32 (m, 3 H, CH₃), 3.61 (m, 8 H, 4 \times CH₂), 3.76 (m, 4 H, 2 \times CH₂), 3.83 (m, 6 H, 3 \times CH₂), 6.48 (s, 1 H, H-5), 6.87 (m, 1 H), 7.04 (m, 2 H), 7.30 (m, 1 H), 7.38 (d, ³ J = 9.0, 1 H), 7.78 (t, ³ J = 9.0, 1 H), 7.85 (t, ³ J = 9.0, 1 H), 8.15 (m, 1 H) ppm. ¹³C NMR (125.7 MHz, CD₃OD): δ = 11.7 (CH₃CH₂), 45.4 (CH₃CH₂), 55.7 (CH₂N), 69.5 (2 \times CH₂), 70.1 (CH₂), 70.5 (CH₂), 70.8 (CH₂), 71.1 (CH₂), 71.4 (CH₂), 103.2 (CH), 103.4 (CH), 109.3 (CH), 117.2 (CH), 119.4 (C),

129.4 (CH), 130.7 (CH), 131.1 (CH), 131.6 (CH), 134.8 (CH), 150.3 (C), 156.4 (C), 162.7 (C), 168.9 (CO) ppm. ESI-MS, negative mode, m/z (rel. int., %): 532 (100) $[M - H]^-$, 488 (25) $[M - H - CO_2]^-$, positive mode, m/z (rel. int., %): 534 (100) $[M + H]^+$. HR-MS (ESI, positive mode): found: 534.2104; calcd. for $C_{30}H_{31}NO_8$: 534.2128 $[M + H]^+$.

Compound Ic-Me•2/3TsOH: According to the GP1, benzophenone **69** (57 mg, 0.22 mmol),

p-toluene sulfonic acid monohydrate (4.0 mg, 21 μ mol) and compound **42c** (52 mg, 0.15 mmol) were heated for 48 h and gave, after purification by chromatography on silica gel (20 g) with CH_2Cl_2 / MeOH mixture (10:1 \rightarrow 3:1) as an eluent, the title compound as a red foam (19 mg, 18%).

HPLC: 80/20 \rightarrow 10/90 (A/B) in 40 min, 1 mL/min, 25 $^{\circ}C$, t_R = 15.4 min, detection at 254 nm. 1H NMR (300 MHz, CD_3OD): δ = 2.34 (s, 2 H = $2/3 \times CH_3(Ts)$), 3.27 (m, 2 H, CH_2), 3.54 (m, 4 H, $2 \times CH_2$), 3.64 (m, 6 H, $3 \times CH_2$), 3.76 (m, 6 H = $COOCH_3$ + CHH + CH_2), 3.95 (m, 3 H = CHH + NCH_2COOH), 6.25 (s, 1 H), 6.54 (m, 2 H, H-2/5), 6.68 (d, 1 H, 4J = 2.2, H-4), 7.21 (m, 3 $1/3$ H, H-1 + $2/3 \times 2$ H(Ts) + H-7'), 7.60 (m, 3 $1/3$ H, $2/3 \times 2$ H(Ts) + H-5'/6'), 8.05 (d, 1 H, 3J = 7.5, H-4') ppm. ^{13}C NMR (75.5 MHz, CD_3OD): δ = 21.3 (Me_{Ts}), 53.2 (CH_2COOCH_3), 56.2 (CH_2CH_2N), 56.9 (CH_2COOCH_3), 67.9 (CH_2), 68.3 (CH_2), 68.8 (CH_2), 68.9 (CH_2), 69.2 ($2 \times CH_2$), 70.3 (CH_2), 103.5 (CH), 110.6 (CH), 112.3 (C), 113.8 (CH), 115.9 (C), 125.2 (CH), 126.1 (CH), 127.0 ($2 \times CH_{Ts}$), 127.9 (C), 129.8 ($2 \times CH_{Ts}$), 130.0 (CH), 131.4 (CH), 136.7 (CH), 141.6 (C_{Ts}), 144.1 (C), 147.6 (C_{Ts}), 149.5 (C), 153.9 (C), 154.0 (C), 161.4 (C), 171.3 (CO), 175.2 (CO) ppm. ESI-MS, negative mode, m/z (rel. int., %): 576 (100) $[M - H]^-$, positive mode, m/z (rel. int., %): 600 (100) $[M + Na]^+$. HR-MS (ESI) negative mode: found: 576.1867; calcd. for $C_{31}H_{31}NO_{10}S \cdot C_7H_8O_3S$: 576.1870 $[M - H]^-$, positive mode: found: 578.2022; calcd. for $C_{31}H_{31}NO_{10}S \cdot C_7H_8O_3S$: 578.2026 $[M + H]^+$.

Indicator Ic: Compound **Ic-Me•2/3TsOH** (19 mg, 0.03 mmol) was dissolved in MeOH (1

mL), then K_2CO_3 (8.9 mg, 0.06 mmol) was added, and the mixture was stirred at room temperature for 1 h. The solvent was removed in vacuo and the residue was dissolved in water (2 mL). This solution was passed through the column with an ion-exchange resin in H^+ -form. The water was removed by the freeze dryer. The residue was purified by

preparative HPLC with reversed phase and gradient eluting with H₂O / MeCN mixture (2:8 → 9:1, 40 min, 4 mL/min, 25 °C, t_R = 12.5 min), and the title compound was isolated as red-orange film (1.5 mg, 9.8%). HPLC: 80/20 → 10/90 (A/B) in 40 min, 1 mL/min, 25 °C, t_R = 12.8 min, detection at 254 nm. ¹H NMR (600 MHz, CD₃OD): δ = 3.52 (m, 2 H, NCH₂COOH), 3.62 (m, 8 H, 4×CH₂), 3.73 (m, 4 H, 2×CH₂), 3.82 (m, 1 H, CHH), 3.95 (m, 1 H, CHH), 4.12 (m, 2 H, CH₂), 6.28 (s, 1 H, H-5), 6.64 (m, 1 H), 6.72 (m, 1 H), 6.78 (s, 1 H), 7.12 (m, 1 H), 7.26 (d, ³ J = 9.0, 1 H), 7.73 (t, ³ J = 9.0, 1 H), 7.79 (t, ³ J = 9.0, 1 H), 8.09 (d, ³ J = 9.0, 1 H) ppm. ¹³C NMR (125.7 MHz, CD₃OD): δ = 55.5 (CH₂CH₂N), 57.2 (CH₂COOCH₃), 69.1 (CH₂), 69.3 (CH₂), 70.0 (CH₂), 70.1 (CH₂), 70.2 (CH₂), 70.3 (CH₂), 70.77 (CH₂), 70.81 (CH₂), 103.3 (CH), 110.6 (CH), 114.9 (CH), 125.2 (CH), 126.1 (CH), 130.4 (CH), 131.3 (CH), 133.9 (C), 135.9 (CH), 146.8 (C), 149.6 (C), 154.8 (C), 162.6 (C), 170.5 (CO) ppm. ESI-MS, negative mode, m/z (rel. int., %): 584 (100) [M – 2H + Na][–]. HR-MS (ESI, positive mode): found: 608.1495; calcd. for C₃₀H₂₉NO₁₀: 608.1503 [M – H + 2Na]⁺.

Indicator 70: According to the GP1, benzophenone **69** (81 mg, 0.31 mmol), *p*-toluene

sulfonic acid monohydrate (4.0 mg, 21 μ mol) and compound **68** (65 mg, 0.21 mmol) were heated for 24 h and gave, after purification by chromatography on silica gel (50 g) with CH₂Cl₂ / MeOH mixture (10:1 → 5:1) as an eluent followed by preparative HPLC and gradient elution with H₂O / MeCN mixture (7:3 → 2:8, in 40 min, 16 mL/min, 25 °C, t_R = 9.9 min), the title compound as a red foam (5.6 mg,

5.0%). HPLC: 80/20 → 10/90 (A/B) in 40 min, 1 mL/min, 25 °C, t_R = 15.5 min, detection at 500 nm. ¹H NMR (300 MHz, CD₃OD): δ = 3.57 (s, 4 H, 2×CH₂), 3.62 (m, 4 H, 2×CH₂), 3.67 (m, 4 H, 2×CH₂), 3.88 (m, 4 H, 2×CH₂), 3.94 (m, 4 H, 2×CH₂), 6.96 (dd, ³ J = 8.4, ⁴ J = 2.1, 1 H, H-2), 7.13 (d, ⁴ J = 2.1, 1 H, H-4), 7.16 (m, 1 H), 7.21 (m, 3 H), 7.42 (m, 1 H), 7.84 (m, 2 H), 8.33 (m, 1 H) ppm. ¹³C NMR (125.7 MHz, CD₃OD): δ = 55.2 (2×CH₂N), 69.6 (2×CH₂), 70.9 (2×CH₂), 71.6 (2×CH₂), 71.9 (2×CH₂), 98.5 (CH), 103.3 (CH), 116.3 (C), 116.4 (C), 117.8 (CH), 118.2 (CH), 130.7 (CH), 131.6 (CH), 131.8 (C), 132.0 (CH), 132.5 (CH), 134.0 (CH), 136.3 (C), 158.2 (C), 159.4 (C), 159.6 (C), 168.1 (C), 168.6 (CO) ppm. ESI-MS, negative mode, m/z (rel. int., %): 532 (100) [M – H][–], positive mode, m/z (rel. int., %): 556 (50) [M + Na]⁺, 572 (100) [M + K]⁺. HR-MS (ESI, negative mode): found: 532.1973; calcd. for C₃₀H₃₁NO₈: 532.1971 [M – H][–].

1,2-Dimethyl-4,5-dinitrobenzene (77): According to the procedure for the preparation of 2,5-dinitrotoluene from 2-methyl-4-nitroaniline,^[107] 4,5-dimethyl-2-nitroaniline (**75**) (25 g, 0.15 mol) was oxidized first with K₂S₂O₈ (122 g, 0.45 mol) in conc. H₂SO₄ (82 mL) (to the corresponding nitroso compound **76**), and then with fuming nitric acid (80 mL).^[107] The title compound was isolated as a colorless needles after recrystallization from EtOH (14.8 g, 50%); m. p. 118 °C (Lit.^[142] 118 °C). ¹H NMR (300 MHz): δ = 2.39 (s, 3 H), 7.65 (s, 1 H) ppm. EI-MS, positive mode, m/z (rel. int., %): 196 (100) [M]⁺.

4,5-Dimethyl-2-nitrophenyl methyl ether (83): In the flask equipped with a reflux condenser, sodium (62 mg, 2.7 mmol) was dissolved in MeOH (5 mL). The solution was cooled to 0 °C, and compound **77** (0.51 g, 2.6 mmol) was added in small portions. The reaction mixture was stirred at 0 °C for 1 h, and then heated at 65 °C for 2 days. The solvent was removed in vacuo, the residue was diluted with water (10 mL) and extracted with EtOAc (3×20 mL). The combined organic solutions were washed with brine (20 mL) and dried. The solvent was removed in vacuo, the residue was purified by chromatography on silica gel (50 g) with *n*-hexane / EtOAc mixture (8:1) as an eluent, and the title compound was isolated as pale yellow needles after recrystallization from *n*-hexane (0.38 g, 81%); m. p. 75 °C (Lit.^[109] 79 °C). ¹H NMR (300 MHz): δ = 2.22 (s, 3 H, CH₃Ar), 2.29 (s, 3 H, CH₃Ar), 3.90 (s, 3 H, CH₃O), 6.83 (s, 1 H), 7.67 (s, 1 H) ppm. ¹³C NMR (75.5 MHz): δ = 18.6 (CH₃Ar), 20.5 (CH₃Ar), 56.5 (CH₃O), 114.7 (CH), 126.7 (CH), 128.8 (C), 136.9 (C), 144.6 (C), 151.2 (C) ppm. ESI-MS, positive mode, m/z (rel. int., %): 204 (51) [M + Na]⁺, 385 (100) [2M + Na]⁺. HR-MS (ESI, positive mode): found: 204.0637; calcd. for C₉H₁₁NO₃: 204.0637 [M + H]⁺.

4-Methoxy-5-nitrophthalic acid (79): According to procedure, described for the preparation of 4-methoxyphthalic acid (**81**) from 3,4-dimethylphenyl methyl ether (**80**),^[108] compound **83** (5.0 g, 28 mmol) was oxidized with KMnO₄ (24 g, 0.15 mol) under basic condition [NaOH (1.1 g, 28 mmol) / water (400 mL)]. The title compound was isolated as a colourless solid after recrystallization from H₂O (4.0 g, 74%); m. p. 199 °C (Lit.^[109] 201 °C). ¹H NMR (300 MHz, CD₃OD): δ = 4.03 (s, 3 H), 7.45 (s, 1 H), 8.30 (s, 1 H) ppm. ¹³C NMR (75.5 MHz, CD₃OD): δ = 57.8 (CH₃O), 114.5 (CH), 128.1 (CH), 140.9 (C), 156.1 (C) ppm. ESI-MS, negative mode, m/z (rel. int., %): 240 (100) [M – H][–].

4-amino-5-hydroxy-N-methylphthalimide (90)^[113]: 10% Pd/C (100 mg) and MeOH (10

mL) were placed into the Schlenk-flask equipped with a septum. The mixture was flushed with hydrogen and stirred vigorously to activate the catalyst. A solution of compound **89** (0.50 g, 1.9 mmol) in MeOH/H₂O mixture (3:1 v/v, 100 mL) was introduced through a septum. The solution

was stirred under H₂ for 4 h at room temperature. Then the hydrogen gas was replaced by argon, and the mixture was filtered through Celite[®]. The filter-cake was washed with MeOH (3×50 mL), and the solvent was removed in vacuo. The obtained mixture was diluted with toluene (10 mL), and the solvent was evaporated once more. The dry residue was dissolved in water (15 mL), and dry acetic acid (2 mL) was added to this solution. The title compound was filtered off, washed with water and air-dried. A yellow solid (285 mg, 78%) was obtained; m. p. > 300 °C (Lit.^[113] 313–315 °C). HPLC: 70/30 → 20/80 (A/B) in 25 min, 1 mL/min, 25 °C, *t*_R = 4.2 min, detection at 254 nm. ¹H NMR (300 MHz, [D₆]DMSO): δ = 2.90 (s, 3 H), 5.67 (br s, 2 H, NH₂), 6.94 (s, 1 H), 6.97 (s, 1 H) ppm. ESI-MS, negative mode, *m/z* (rel. int., %): 191 (48) [M – H][–], 383 (100) [2M – H][–], positive mode, *m/z* (rel. int., %): 215 (29) [M + Na]⁺, 407 (100) [2M + Na]⁺. HR-MS (ESI) negative mode: found: 191.0462; calcd. for C₉H₈N₂O₃: 191.0457 [M – H][–], positive mode: found: 215.0435; calcd. for C₉H₈N₂O₃: 215.0433 [M + Na]⁺.

Crown ether 92: Method 1: To a solution of compound **90** (52 mg, 0.27 mmol) in a dry DMF

(2 mL) in a dry Schlenk-flask equipped with a septum, NaI (81 mg, 0.54 mmol) and DIPEA (143 μL, *d* = 0.74, 0.82 mmol) were added at room temperature, and the reaction mixture was vigorously stirred. Then compound **91** (112 mg, 0.27 mmol) was

added, and the reaction mixture was heated at 90 °C for 1 day. All volatile materials were removed in vacuo, and the residue was diluted with CH₂Cl₂ (10 mL). The organic solution was washed with water (10 mL) and dried. Dichloromethane was evaporated, and the residue was purified by chromatography on silica gel (30 g) with CH₂Cl₂ / MeCN mixture (1:8) as an eluent. The title compound was isolated as a yellow solid (14 mg, 15%); m. p. 236 °C (MeOH). HPLC: 70/30 → 20/80 (A/B) in 25 min, 1 mL/min, 25 °C, *t*_R = 11.9 min, detection at 254 nm. ¹H NMR (300 MHz): δ = 3.07 (s, 3 H), 3.32 (m, 2 H, CH₂N), 3.65 (m, 6 H, 3×CH₂), 3.71 (m, 2 H, CH₂), 3.77 (m, 2 H, CH₂), 3.86 (m, 2 H, CH₂), 4.18 (m, 2 H, CH₂), 5.64 (br s, 1 H, NH), 6.87 (s, 1 H), 7.06 (s, 1 H) ppm. ¹³C NMR (125.7 MHz): δ = 23.7 (CH₃),

42.7 (CH₂N), 68.1 (CH₂), 68.2 (CH₂), 68.8 (CH₂), 69.8 (CH₂), 69.96 (CH₂), 70.02 (CH₂), 70.2 (CH₂), 102.7 (CH), 104.5 (CH), 119.6 (C), 127.4 (C), 143.9 (C), 149.2 (C), 169.4 (C), 169.5 (CO) ppm. ESI-MS, positive mode, m/z (rel. int., %): 373 (100) [M + Na]⁺, 723 (22) [2M + Na]⁺. HR-MS (ESI, positive mode): found: 373.1373; calcd. for C₁₇H₂₂N₂O₆: 373.1370 [M + Na]⁺.

2-[2-[2-[2-(2-Methyl-6-nitro-1*H*-isoindole-1,3(2*H*)-dion-5-yloxy)ethoxy]-ethoxy]-ethoxy]-

ethyl acetate (93-Ac): In a dry Schlenk-flask equipped with a septum and flushed with nitrogen, compound **89** (1.0 g, 3.8 mmol) was dissolved in DMF

(10 mL). Then KI (0.65 g, 3.9 mmol) and compound **54-Ac** (1.2 g, 4.7 mmol) were added to the reaction mixture, and it was heated at 110 °C for 3 days. The solvent was evaporated in vacuo, and the residue was diluted with CH₂Cl₂ (30 mL) and mixed with water (30 mL). The organic layer was separated, washed with saturated aq. Na₂CO₃ (2×50 mL) and dried. The solvent was removed in vacuo, the residue was purified by chromatography on silica gel (100 g) with CH₂Cl₂ / MeOH mixture (40:1) as an eluent, and the title compound was isolated as a pale yellow liquid (0.70 g, 42%). ¹H NMR (300 MHz): δ = 2.05 (s, 3 H, CH₃CO), 3.17 (s, NCH₃), 3.67 (m, 10 H), 3.91 (m, 2 H), 4.18 (m, 2 H), 4.39 (m, 2 H), 7.58 (s, 1 H), 8.15 (s, 1 H) ppm. ¹³C NMR (75.6 MHz): δ = 20.9 (CH₃CO), 24.5 (CH₃N), 63.6 (CH₂OAc), 69.0 (CH₂), 69.1 (CH₂), 70.53 (CH₂), 70.57 (CH₂), 70.6 (CH₂), 70.7 (CH₂), 71.1 (CH₂), 109.6 (CH), 120.6 (CH), 123.4 (C), 136.5 (C), 143.1 (C), 156.9 (C), 166.1 (CO), 166.4 (CO), 171.0 (CH₃CO) ppm. ESI-MS, positive mode, m/z (rel. int., %): 463 (100) [M + Na]⁺. HR-MS (ESI, positive mode): found: 463.1325; calcd. for C₁₉H₂₄N₂O₁₀: 463.1329 [M + Na]⁺.

5-[2-[2-(2-Hydroxyethoxy)-ethoxy]-ethoxy]-ethoxy-2-methyl-6-nitro-1*H*-isoindole-

1,3(2*H*)-dion (93-H): Method 1: To a solution of compound **93-Ac** (0.69 g, 1.6 mmol) in MeOH/ CH₂Cl₂ mixture (4:1 v/v, 100 mL), K₂CO₃ (50 mg, 0.36 mmol) was

added. The reaction mixture was stirred for 1 h at room temperature. The solvent was evaporated in vacuo. The residue was diluted with CH₂Cl₂ (30 mL) and mixed with water (10 mL). The organic solution was washed with brine and dried. The solvent was removed in vacuo, the residue was purified by chromatography on silica gel (70 g) with CH₂Cl₂ / MeOH

mixture (30:1) as an eluent, and the title compound was isolated as a pale yellow liquid (0.31 g, 49%). HPLC: 70/30 → 20/80 (A/B) in 25 min, 1 mL/min, 25 °C, t_R = 8.6 min, detection at 254 nm. ^1H NMR (300 MHz): δ = 3.17 (s, NCH_3), 3.57 (m, 2 H, CH_2OH), 3.67 (m, 10 H), 3.91 (m, 2 H), 4.40 (m, 2 H), 7.61 (s, 1 H), 8.16 (s, 1 H) ppm. ^{13}C NMR (75.6 MHz): δ = 24.5 (CH_3N), 61.7 (CH_2OH), 69.0 (CH_2), 70.2 (CH_2), 70.52 (CH_2), 70.58 (CH_2), 70.6 (CH_2), 71.1 (CH_2), 72.4 (CH_2), 109.7 (CH), 120.6 (CH), 123.3 (C), 136.5 (C), 143.1 (C), 156.9 (C), 166.1 (CO), 166.5 (CO) ppm. ESI-MS, positive mode, m/z (rel. int., %): 421 (100) $[\text{M} + \text{Na}]^+$, 819 (6) $[2\text{M} + \text{Na}]^+$. HR-MS (ESI, positive mode): found: 421.1212; calcd. for $\text{C}_{17}\text{H}_{22}\text{N}_2\text{O}_9$: 421.1223 $[\text{M} + \text{Na}]^+$.

2-[2-[2-(2-Iodoethoxy)-ethoxy]-ethoxy]-ethyl trityl ether (96): To a solution of compound

95 (1.0 g, 1.9 mmol) in dry THF (10 mL), in a dry Schlenk-flask equipped with a septum and flushed with

nitrogen, LiI (0.52 g, 3.9 mmol) was added. The reaction mixture was heated at 40 °C for 1 h, diluted with diethyl ether (25 mL), washed with water (2×25 mL) and dried. The solvent was removed in vacuo, the title compound was isolated as a brownish liquid (0.94 g, 98%). HPLC: 50/50 → 0/100 (A/B) in 25 min, 1 mL/min, 25 °C, t_R = 19.0 min, detection at 254 nm. ^1H NMR (300 MHz): δ = 3.24 (m, 2 H), 3.68 (m, 12 H, $6\times\text{CH}_2$), 3.74 (m, 2 H, CH_2OTr), 7.28 (m, 10 H), 7.37 (m, 5 H) ppm. ^{13}C NMR (75.5 MHz): δ = 2.9 (CH_2I), 63.3 (CH_2OTr), 70.2 (CH_2), 70.7 ($2\times\text{CH}_2$), 70.8 ($2\times\text{CH}_2$), 72.0 (CH_2), 86.5 (CPh_3), 126.9 (CH), 127.7 (CH), 128.7 (CH), 144.1 (C) ppm. ESI-MS, positive mode, m/z (rel. int., %): 569 (100) $[\text{M} + \text{Na}]^+$. HR-MS (ESI, positive mode): found: 569.1163; calcd. for $\text{C}_{27}\text{H}_{31}\text{IO}_4$: 569.1165 $[\text{M} + \text{Na}]^+$.

2-Methyl-6-nitro-5-[2-[2-(2-trityloxyethoxy)-ethoxy]-ethoxy]-ethoxy-1*H*-isoindole-

1,3(2*H*)-dion (93-Tr): In a dry Schlenk-flask equipped with a septum and flushed with nitrogen, compound **89** (1.2 g, 4.6 mmol) was dissolved in DMF (15 mL).

Then compound **96** (4.4 g, 8.1 mmol) was added, and the mixture was heated at 70 °C for 5 days. The solvent was evaporated in vacuo, the residue was diluted with CHCl_3 (50 mL) and mixed with water (50 mL). The organic layer was separated, washed with saturated aq. Na_2CO_3 (2×50 mL), brine and dried. The solvent was removed in vacuo, the residue was purified by chromatography on silica gel (130 g) with *n*-hexane / EtOAc mixture (1:1) as an eluent, and the title compound was isolated as a pale yellow resin (1.7 g, 58%). HPLC: 70/30

→ 20/80 (A/B) in 25 min, 1 mL/min, 25 °C, t_R = 9.2 min, detection at 254 nm. ^1H NMR (300 MHz): δ = 3.17 (s, NCH₃), 3.21 (CH₂OTr), 3.67 (m, 10 H), 3.88 (m, 2 H), 4.26 (m, 2 H), 7.23 (m, 10 H), 7.44 (m, 5 H), 7.48 (s, 1 H), 8.14 (s, 1 H) ppm. ^{13}C NMR (75.5 MHz): δ = 24.4 (CH₃N), 63.3 (CH₂OTr), 69.0 (CH₂), 70.61 (CH₂), 70.65 (CH₂), 70.73 (CH₂), 70.76 (CH₂), 70.78 (CH₂), 71.1 (CH₂), 86.5 (CPh₃), 109.6 (CH), 120.5 (CH), 123.3 (C), 126.9 (CH), 127.7 (CH), 128.7 (CH), 136.5 (C), 144.1 (C), 146.8 (C), 156.9 (C), 166.1 (CO), 166.4 (CO) ppm. ESI-MS, negative mode, m/z (rel. int., %): 657 (100) [M + OH]⁻, positive mode, m/z (rel. int., %): 663 (100) [M + Na]⁺. HR-MS (ESI, positive mode): found: 663.2315; calcd. for C₃₆H₃₆N₂O₉: 663.2319 [M + Na]⁺.

5-[2-[2-(2-Hydroxyethoxy)-ethoxy]-ethoxy]-ethoxy-2-methyl-6-nitro-1*H*-isoindole-

1,3(2*H*)-dion (93-H): *Method 2 (see Method 1 on page 154):* To a solution of compound **93-Tr** (100 mg, 0.16 mmol) in MeOH/ CH₂Cl₂ mixture (4:1 v/v, 5 mL), 2

M solution of BF₃•Et₂O in MeOH (100 μL, 0.2 mmol) was added. The reaction mixture was stirred overnight at room temperature. The solvent was evaporated in vacuo, and the residue was diluted with CH₂Cl₂ (30 mL). The organic solution was washed with water and with brine, and dried. The solvent was removed in vacuo, the residue was purified by chromatography on silica gel (20 g) with CH₂Cl₂ / MeOH mixture (50:1) as an eluent, and the title compound was isolated as a pale yellow resin (61 mg, 96%). The NMR and mass spectra were reported above.

5-Amino-6-[2-[2-(2-hydroxyethoxy)-ethoxy]-ethoxy]-ethoxy-2-methyl-1*H*-isoindole-

1,3(2*H*)-dion (97): According to the GP2, compound **93-H** (300 mg, 0.75 mmol) was reduced in MeOH and gave the title compound as a yellow oil (260 mg, 94%).

HPLC: 50/50 → 0/100 (A/B) in 25 min, 1 mL/min, 25 °C, t_R = 2.7 min, detection at 254 nm. ^1H NMR (300 MHz): δ = 3.06 (s, 3 H), 3.58 (m, 2 H), 3.68 (m, 10 H, 5×CH₂), 3.85 (m, 2 H, CH₂), 4.21 (m, 2 H), 4.80 (s, 1 H, NH₂), 7.01 (s, 1 H), 7.13 (s, 1 H) ppm. ^{13}C NMR (75.6 MHz): δ = 23.7 (CH₃N), 61.6 (CH₂OAr), 68.6 (CH₂), 69.3 (CH₂), 70.2 (CH₂), 70.5 (CH₂), 70.59 (CH₂), 70.64 (CH₂), 72.5 (CH₂), 106.5 (CH), 107.9 (CH), 121.3 (C), 127.2 (C), 143.0 (C), 149.2 (C), 169.1 (CO), 169.2 (CO) ppm. ESI-MS, negative mode, m/z (rel. int., %): 367

(100) $[M - H]^-$, positive mode, m/z (rel. int., %): 391 (100) $[M + Na]^+$, 759 (56) $[2M + Na]^+$. HR-MS (ESI) negative mode: found: 367.1500; calcd. for $C_{17}H_{24}N_2O_7$: 367.1505 $[M - H]^-$, positive mode: found: 391.1470; calcd. for $C_{17}H_{24}N_2O_7$: 391.1481 $[M + Na]^+$.

2-[2-[2-(2-(2-Methyl-6-tosylamino-1*H*-isoindole-1,3(2*H*)-dione-5-yloxy)ethoxy)-ethoxy]-ethoxy]-ethyl tosylate (98):

ethoxy]-ethyl tosylate (98): According to the GP3, compound **97** (1.6 g, 4.3 mmol) and tosyl chloride (1.7 g, 8.9 mmol) gave, after purification by chromatography on

silica gel (200 g) with CH_2Cl_2 / MeOH mixture (40:1) as an eluent, the title compound as a colorless oil (2.1 g, 72%). HPLC: 50/50 \rightarrow 0/100 (A/B) in 25 min, 1 mL/min, 25 $^{\circ}C$, t_R = 11.8 min, detection at 254 nm. 1H NMR (300 MHz): δ = 2.22 (s, 3 H, CH_3), 2.41 (s, 3 H, CH_3), 3.17 (s, 3 H, NCH_3), 3.66 (m, 10 H, $5 \times CH_2$), 3.71 (m, 2 H), 4.14 (m, 4 H, $2 \times CH_2$), 7.21 (m, 2 H_{TsNH} + 1 H), 7.30 (d, 3J = 8.4, 2 H_{TsO}), 7.74 (d, 3J = 8.1, 2 H_{TsNH}), 7.76 (d, 3J = 8.4, 2 H_{TsO}), 7.91 (s, 1 H), 8.12 (s, 1 H, NHTs) ppm. ^{13}C NMR (75.5 MHz): δ = 21.5 (CH_3), 21.6 (CH_3), 24.0 (CH_3N), 68.7 ($\underline{CH_2OTs}$), 68.9 (CH_2), 69.3 (CH_2), 69.7 (CH_2), 70.5 (CH_2), 70.65 (CH_2), 70.73 (CH_2), 70.76 (CH_2), 107.2 (CH), 113.6 (CH), 125.8 (C), 127.3 (CH), 127.9 (CH), 128.4 (C), 129.76 (CH), 129.82 (CH), 132.4 (C), 132.9 (C), 136.0 (C), 144.3 (C), 144.8 (C), 152.0 (C), 167.8 (CO), 168.0 (CO) ppm. ESI-MS, negative mode, m/z (rel. int., %): 675 (100) $[M - H]^-$, positive mode, m/z (rel. int., %): 699 (100) $[M + Na]^+$. HR-MS (ESI, positive mode): found: 699.1658; calcd. for $C_{31}H_{36}N_2O_{11}S_2$: 699.1653 $[M + Na]^+$.

Crown ether 99: According to the GP4, compound **98** (5.6 g, 8.3 mmol) and caesium

carbonate (3.0 g, 9.2 mmol) in DMF (80 mL) gave, after purification by chromatography on silica gel (200 g) with CH_2Cl_2 / MeOH mixture (50:1) as an eluent, the title compound as a colourless oil (0.90 g, 21%). HPLC: 50/50 \rightarrow 0/100 (A/B) in 25

min, 1 mL/min, 25 $^{\circ}C$, t_R = 8.9 min, detection at 254 nm. 1H NMR (300 MHz): δ = 2.40 (s, 3 H, CH_3), 3.13 (s, 3 H, NCH_3), 3.46 (m, 4 H, $2 \times CH_2$), 3.52 (m, 4 H, $2 \times CH_2$), 3.58 (m, 2 H, CH_2), 3.66 (m, 4 H, $2 \times CH_2$), 3.95 (m, 2 H, CH_2), 7.24 (m, 2 H_{TsNH} + 1 H), 7.57 (d, 3J = 8.1, 2 H_{TsN}), 7.65 (s, 1 H) ppm. ^{13}C NMR (75.5 MHz): δ = 21.5 (CH_3), 24.1 (CH_3N), 50.2 (CH_2), 67.9 (CH_2), 68.3 (CH_2), 69.9 (CH_2), 70.0 (CH_2), 70.6 (CH_2), 70.8 (CH_2), 71.3 (CH_2), 106.9 (CH), 123.8 (C), 127.5 (CH), 127.7 ($2 \times CH$), 129.3 ($2 \times CH$), 133.2 (C), 133.8 (C), 136.7 (C), 143.4 (C), 160.8 (C), 167.5 (CO), 167.8 (CO) ppm. ESI-MS, negative mode, m/z (rel. int.,

539 (100) $[M + Cl]^-$, positive mode, m/z (rel. int., %): 527 (100) $[M + Na]^+$, 1031 (18) $[2M + Na]^+$. HR-MS (ESI, positive mode): found: 527.1464; calcd. for $C_{24}H_{28}N_2O_8S$: 527.1464 $[M + Na]^+$.

2-[2-[2-[2-(2-Methyl-6-nitro-1*H*-isoindole-1,3(2*H*)-dione-5-yloxy)ethoxy]-ethoxy]-ethoxy]-

ethyl tosylate (101): According to the GP3, compound **93-H** (1.1 g, 2.8 mmol) and tosyl chloride (0.78 g, 4.1 mmol) gave, after purification by chromatography

on silica gel (100 g) with CH_2Cl_2 / EtOAc mixture (2:1→1:1) as an eluent, the title compound as a pale yellow oil (0.80 g, 52%). 1H NMR (300 MHz): δ = 2.41 (s, 3 H, CH_3), 3.18 (s, 3 H, NCH_3), 3.66 (m, 10 H, $5 \times CH_2$), 3.91 (m, 2 H, CH_2), 4.12 (m, 2 H, CH_2), 4.38 (m, 2 H, CH_2), 7.30 (d, $^3J = 8.4$, 2 H_{TsO}), 7.58 (s, 1 H), 7.74 (d, $^3J = 8.4$, 2 H_{TsO}), 8.15 (s, 1 H) ppm. ^{13}C NMR (75.5 MHz): δ = 21.6 (CH_3), 24.5 (CH_3N), 68.6 ($\underline{CH_2}OTs$), 69.0 (CH_2), 69.2 (CH_2), 70.5 (CH_2), 70.67 (CH_2), 70.72 ($2 \times CH_2$), 71.1 (CH_2), 109.7 (CH), 120.5 (CH), 123.4 (C), 127.9 (CH), 129.8 (CH), 133.0 (C), 136.6 (C), 143.1 (C), 144.8 (C), 156.9 (C), 166.1 (CO), 166.4 (CO) ppm. ESI-MS, positive mode, m/z (rel. int., %): 575 (100) $[M + Na]^+$. HR-MS (ESI, positive mode): found: 575.1307; calcd. for $C_{24}H_{28}N_2O_{11}S$: 575.1312 $[M + Na]^+$.

2-[2-[2-[2-(6-Amino-2-methyl-1*H*-isoindole-1,3(2*H*)-dione-5-yloxy)ethoxy]-ethoxy]-ethoxy]-

ethoxy]-ethyl tosylate (100): According to the GP2, compound **101** (150 mg, 0.27 mmol) was reduced in THF and gave the title compound as a yellow oil (125 mg,

89%). HPLC: 70/30 → 20/80 (A/B) in 25 min, 1 mL/min, 25 °C, t_R = 16.6 min, detection at 254 nm. 1H NMR (300 MHz): δ = 2.40 (s, 3 H, CH_3), 3.06 (s, 3 H), 3.64 (m, 10 H, $5 \times CH_2$), 3.86 (m, 2 H, CH_2), 4.12 (m, 2 H), 4.21 (m, 2 H), 7.02 (s, 1 H), 7.14 (s, 1 H), 7.30 (d, $^3J = 8.4$, 2 H_{TsO}), 7.76 (d, $^3J = 8.4$, 2 H_{TsO}) ppm. ^{13}C NMR (75.6 MHz): δ = 21.6 (CH_3), 23.7 (CH_3N), 68.68 ($\underline{CH_2}OTs$), 68.74 (CH_2), 69.2 (CH_2), 69.3 (CH_2), 70.5 (CH_2), 70.58 (CH_2), 70.63 (CH_2), 70.8 (CH_2), 106.5 (CH), 108.0 (CH), 121.6 (C), 127.1 (C), 127.9 ($2 \times CH$), 129.8 ($2 \times CH$), 132.9 (C), 142.5 (C), 144.8 (C), 149.2 (C), 168.9 (CO), 169.1 (CO) ppm. ESI-MS, negative mode, m/z (rel. int., %): 521 (100) $[M - H]^-$, positive mode, m/z (rel. int., %): 545 (100) $[M + Na]^+$, 1067 (17) $[2M + Na]^+$. HR-MS (ESI, positive mode): found: 545.1567; calcd. for $C_{24}H_{30}N_2O_9S$: 545.1570 $[M + Na]^+$.

5-Amino-6-[2-[2-(2-iodoxyethoxy)-ethoxy]-ethoxy]-ethoxy-2-methyl-1*H*-isoindole-

1,3(2*H*)-dion (102): In the flask equipped with a reflux condenser, compound **100** (0.10 g, 0.19 mmol) was dissolved in acetone (5 mL). Then NaI (86 mg, 0.58 mmol) was

added. The reaction mixture was refluxed overnight, the solvent removed in vacuo, the residue was diluted with water (10 mL) and CH₂Cl₂ (10 mL). The aqueous layer was extracted with CH₂Cl₂ (2×20 mL). The combined organic solutions were washed with water (25 mL) and dried. The solvent was removed in vacuo, the residue was purified by chromatography on silica gel (15 g) with CH₂Cl₂ / MeCN mixture (4:1) as an eluent, and the title compound was isolated as a yellow-brown oil (90 mg, 99%). HPLC: 70/30 → 20/80 (A/B) in 25 min, 1 mL/min, 25 °C, *t_R* = 14.0 min, detection at 254 nm. ¹H NMR (300 MHz): δ = 3.07 (s, 3 H), 3.23 (t, ³*J* = 6.9, 2 H, CH₂I), 3.68 (m, 10 H, 5×CH₂), 3.86 (m, 2 H, CH₂), 4.22 (m, 2 H, CH₂), 7.02 (s, 1 H), 7.16 (s, 1 H) ppm. ¹³C NMR (75.5 MHz): δ = 2.9 (CH₂I), 23.7 (CH₃N), 68.8 (CH₂), 69.4 (CH₂), 70.2 (CH₂), 70.6 (CH₂), 70.7 (CH₂), 70.8 (CH₂), 71.9 (CH₂), 106.5 (CH), 108.0 (CH), 121.7 (C), 127.1 (C), 142.5 (C), 149.3 (C), 169.0 (CO), 169.1 (CO) ppm. ESI-MS, negative mode, *m/z* (rel. int., %): 477 (100) [M – H][–], positive mode, *m/z* (rel. int., %): 501 (100) [M + Na]⁺, 979 (20) [2M + Na]⁺. HR-MS (ESI) negative mode: found: 477.0520; calcd. for C₁₇H₂₃IN₂O₆: 477.0523 [M – H][–], positive mode: found: 501.0502; calcd. for C₁₇H₂₃IN₂O₆: 501.0499 [M + Na]⁺.

Crown ether 92: Method 2 (see Method 1 on page 153): To a solution of compound **102** (60

mg, 0.13 mmol) in dry DMF (2 mL) in a dry Schlenk-flask equipped with a septum, NaI (38 mg, 0.25 mmol) and DIPEA (66 μL, *d* = 0.75, 0.39 mmol) were added at room temperature, and the reaction mixture was heated at 90 °C for 1 day. All volatile

materials were evaporated in vacuo, and the residue was diluted with CH₂Cl₂ (10 mL). The organic solution was washed with water (10 mL), dried and evaporated. The residue was purified by chromatography on silica gel (30 g) with CH₂Cl₂ / MeCN mixture (1:8) as an eluent, and the title compound was isolated as a yellow solid (18 mg, 40%). The NMR and mass spectra were reported above.

Crown ether 92-Et: A mixture of compound **92** (17 mg, 0.05 mmol) and Et₂SO₄ (0.2 mL, d = 1.18, 1.5 mmol) was heated at 140 °C for 1 h under anhydrous conditions. After cooling to

room temperature, the mixture was diluted with ethanol (5 mL) and poured into ice-cold water (10 mL). It was stirred for 2 h. The aqueous solution was extracted with CH₂Cl₂ (2×20 mL). The combined organic solutions were dried. The solvent was removed

in vacuo, the residue was purified by chromatography on silica gel (30 g) with CH₂Cl₂ / MeOH mixture (25:1) as an eluent, and the title compound was isolated as a yellow oil (15 mg, 81%). HPLC: 70/30 → 20/80 (A/B) in 25 min, 1 mL/min, 25 °C, *t_R* = 4.6 min, detection at 254 nm. ¹H NMR (300 MHz): δ = 1.13 (t, ³*J* = 7.2, 3 H, CH₂CH₃), 3.08 (s, 3 H), 3.33 (q, ³*J* = 7.2, 2 H, CH₂CH₃), 3.39 (t, ³*J* = 7.8, 2 H, CH₂N), 3.66 (m, 8 H, 4×CH₂), 3.82 (t, ³*J* = 7.2, 2 H, CH₂), 3.92 (m, 2 H, CH₂), 4.21 (m, 2 H, CH₂), 7.27 (s, 1 H), 7.30 (s, 1 H) ppm. ¹³C NMR (75.5 MHz): δ = 12.4 (CH₂CH₃), 23.8 (CH₃N), 46.3 (CH₂CH₃), 52.5 (CH₂CH₂N), 68.7 (CH₂), 69.2 (2×CH₂), 69.9 (CH₂), 70.1 (CH₂), 70.2 (CH₂), 70.7 (CH₂), 106.3 (CH), 111.8 (CH), 123.7 (C), 125.8 (C), 145.5 (C), 154.8 (C), 169.0 (CO), 169.2 (CO) ppm. ESI-MS, positive mode, *m/z* (rel. int., %): 379 (20) [M + H]⁺, 401 (100) [M + Na]⁺. HR-MS (ESI, positive mode): found: 379.1862, 401.1685; calcd. for C₁₉H₂₆N₂O₆: 379.1869 [M + H]⁺, 401.1689 [M + Na]⁺.

SplAsH-RhS-OF: According to the GP6, compound **118-Me** (5.5 mg, 7.3 μmol) and compound **105a** (15 mg, 21 μmol) gave the title compound as a pink solid (3.1 mg, 32%). Preparative HPLC: 60/40 → 0/100 (A/B) in 25 min, 4 mL/min, 7 °C, *t_R* = 10.1 min, detection at 530 nm. Analytical HPLC: 60/40 → 0/100 (A/B) in 25 min, 1 mL/min, 7 °C, *t_R* = 12.8 min, detection at 530 nm. ESI-MS, positive mode, *m/z* (rel. int., %): 1388 (100) [M + 2Na – H]⁺. HR-MS (ESI, positive mode): found: 1387.9951; calcd. for C₅₆H₅₁As₂N₅O₁₃S₆: 1387.9957 [M + 2Na – H]⁺.

SplAsH-RhS-CF: According to the GP6, compound **118-H** (6.0 mg, 8.1 μmol) and compound **105a** (15 mg, 21 μmol) gave the title compound as a light rosy solid (2.0 mg, 19%). Preparative HPLC: 60/40 \rightarrow 0/100 (A/B) in 25 min, 4 mL/min, 7 $^{\circ}\text{C}$, t_{R} = 9.7 min, detection at 530 nm. Analytical HPLC: 80/20 \rightarrow 50/50 (A/B) in 25 min, 1 mL/min, 25 $^{\circ}\text{C}$, t_{R} = 10.7 min, detection at 254 nm. ESI-MS, negative mode, m/z (rel. int., %): 1350 (100) $[\text{M} + \text{Na} - 2\text{H}]^{-}$, positive mode, m/z (rel. int., %): 1390 (100) $[\text{M} + \text{Na} + \text{K} - \text{H}]^{+}$. HR-MS (ESI, negative mode): found: 663.4969; calcd. for $\text{C}_{55}\text{H}_{49}\text{As}_2\text{N}_5\text{O}_{13}\text{S}_6$: 663.4963 $[\text{M} - 2\text{H}]^{2-}$.

SplAsH-TAMRA: To a solution of the NHS-ester of carboxy TMR-rhodamine (**119**) (2.5 mg, 4.7 μmol) and DIPEA (10 μL , $d = 0.72$, 57 μmol) in a dry DMF (0.75 mL), the solution of compound **105a** (10 mg, 14 μmol) in CH_2Cl_2 (0.5 mL) was added via a syringe, and the reaction mixture was stirred at room temperature for 6 h. Then all volatile materials were removed in vacuo (without heating). The residue was purified by the column reversed-phase chromatography and gradient eluting first with MeCN / H_2O mixture (4:1 \rightarrow 10:1) and then with MeOH. The residue after freeze-drying was purified by preparative HPLC: 50/50 \rightarrow 0/100 (A/B) in 25 min, 16 mL/min, 25 $^{\circ}\text{C}$, t_{R} = 11.8 min, detection at 547 nm. The solvents were removed by the freeze-drying. The title compound was isolated as a red solid (3.3 mg, 62%). Analytical HPLC: 50/50 \rightarrow 0/100 (A/B) in 25 min, 1 mL/min, 25 $^{\circ}\text{C}$, t_{R} = 13.7 min,

detection at 254 nm. ESI-MS, negative mode, m/z (rel. int., %): 1117 (100) $[M - H]^-$, positive mode, m/z (rel. int., %): 1119 (100) $[M + H]^+$, 1141 (100) $[M + Na]^+$. HR-MS (ESI, negative mode): found: 1119.0540; calcd. for $C_{51}H_{44}As_2N_4O_8S_4$: 1119.0552 $[M + H]^+$.

Summary

In the present work, the crown ether-containing rhodol dyes (compounds **Ia**, **Ib**, **Ic**, **70**) have been synthesized, and their spectral as well as their calcium-indicator properties have been investigated in methanolic and aqueous solutions. As a part of this study, the feasibility of the synthesis of the target sensors **Ia-c** was evaluated by performing the synthesis of some simplified model compounds. A total synthesis of the colorless rhodole spiroamide **40-H** (model compound for the target **Ia-c**, **IIa,b**) was developed, and the photoactivation of the latter by irradiation with UV light was tested. This compound was found to be photosensitive (under irradiation at 366 nm), and it gave a fluorescent species in toluene solution.

The excitation and emission maxima of all prepared dyes are above 450 nm ($\lambda_{abs}^{max} = 513\text{--}542\text{ nm}$ ($\epsilon = (2.2\text{--}5.2) \times 10^4\text{ M}^{-1}\text{cm}^{-1}$), $\lambda_{fl}^{max} = 539\text{--}558\text{ nm}$), and fulfil the required spectral criteria for calcium indicators (see section 1 of Chapter 1). The “brightness” ($\epsilon \cdot \Phi$) varies from 3500 (for compound **Ib**) to $41600\text{ M}^{-1}\text{cm}^{-1}$ (for compound **70**). The absorption and emission spectra of all prepared rhodols do not depend on the pH (in the range of intracellular pH values, i. e. pH = 6–8).

A junction of the crown ether with an aromatic ring in the xanthene moiety through only one heteroatom (nitrogen) leads to a lower response upon the presence of calcium in the medium than in the case of the fusion of the crown ether with the xanthene by two heteroatoms. This conclusion was confirmed by the absence of changes in the fluorescence signal of aqueous solutions of compound **70** in the absence and presence of calcium ions.

Compound **Ia** with an NH group in the crown-ether ring was not sensitive to calcium at any pH value in aqueous solution, and the same feature was observed for compound **Ic** with a CH_2COOH substituent at the nitrogen atom of the crown-ether ring. However, the fluorescence of compound **Ib** with an ethyl group at the nitrogen atom of the crown-ether ring strongly increased in the presence of calcium cations in the millimolar range (1–126 mM). The observed dependence failed to fit any of the most obvious models, such as the formation of 1 : 1 and 2 : 1 complexes between the indicator and calcium. Therefore, the stability constant of the complex cannot be calculated.

Key precursors (compounds **92**, **92-Et**) to the target compounds **IIa,b** were prepared. It was established, that the most efficient route to compound **92** is by twofold alkylation of 4-amino-5-hydroxy-*N*-methylphthalimide **90** with the diiodide **91**. In spite of the low yield of compound **92** (14%), the shorter sequence is preferable, because the longer route with

consecutive alkylation of the nitrophenolic salt **89** by the iodide **96**, deprotection, tosylation, reduction, nucleophilic substitution and cyclization provides the same overall yield (14%).

Several fluorescent labels for the tetracysteine tags in proteins with the water-soluble orange-emitting dye Rhodamine S (**SplAsH-RhS-OF**), with the same dye in the masked spiroamide form (**SplAsH-RhS-CF**) and with TMR-dye (**SplAsH-TAMRA**) were prepared, and their binding and staining properties were investigated. Due to the extreme instability of compounds **SplAsH-RhS-OF** and **SplAsH-RhS-CF**, a special HPLC procedure for their isolation was elaborated. The binding properties were evaluated in competitive mode with F_lAsH (Fluorescein Arsenic Hairpin binder) fluorimetrically. Comparison of the fluorescence intensity in a control experiment (F_lAsH + peptide with the tetracysteine fragment) and for the same mixture with the added compound **SplAsH-RhS-OF**, confirmed the binding ability of the SplAsH derivatives. The second series of experiments with the non-fluorescent compound **SplAsH-RhS-CF**, instead of the orange-emitting **SplAsH-RhS-OF**, provided information on the binding ability of F_lAsH in a competitive assay: the amount of unbound (non-fluorescent) F_lAsH was 7 times higher than that of the bound (fluorescent) form. This result confirmed the good binding properties of the SplAsH derivatives (**SplAsH-RhS-OF**, **SplAsH-RhS-CF**).

The third series of experiments dealt with the labelling of proteins with some SplAsH-containing compounds. The proteins differ from each other by the number of tetracysteine moieties (2 or 3) and the “degrees of freedom” (free protein or the protein incorporated into cell structures). The labels could be introduced into organelles inside live cells or into isolated cell structures. In all experiments with isolated proteins, products of their binding with **SplAsH-RhS-OF** could be detected. However, the introduction of the **SplAsH-RhS-OF** label into proteins in live cells was not selective. This conclusion was made by studying the cell images in the confocal microscope. The entire cells were colored, without any preference for the structures with tetracysteine tags.

Further, labelling of mitochondria with **SplAsH-TAMRA** was attempted. It is well-known, that rhodamines are preliminarily localized in mitochondria.^[141] Therefore, this property was expected to help in introducing the SplAsH labels into mitochondria. However, using **SplAsH-TAMRA**, the same picture as in the case of **SplAsH-RhS-OF** was observed (the entire cells were colored inside). Therefore, the mitochondria could not be labelled selectively by the marker **SplAsH-TAMRA**.

Acknowledgements

I would like to thank:

– Prof. Dr. Stefan W. Hell for giving me an opportunity to work in his excellent group, for his help and financial support during the difficult period of work on my PhD thesis, for the perfect working conditions in his department.

– my supervisor Prof. Dr. A. de Meijere for leadership, patience, appreciation and help in my thesis preparation.

– my laboratory advisor Dr. Vladimir Belov for his patience and readiness to work with me, for the leadership and professional approach to the organic synthesis, for the interesting discussions and advice, for the development of my character as a scientist, for the all-round support and help in my work.

– Prof. Dr. Mariano Bossi for the spectroscopic experiments, interest and productive discussions on scientific problems in the cooperative work, for the help in the preparation of numerous plots for my thesis.

– Priv.-Doz. Stefan Jacobs and Dr. Stefan Stoldt for the cooperation, interesting discussions and productive work in the area of selective labeling of proteins in living cells.

– the NMR-team and its head Dipl.-Chem. R. Machinek for the fast and precise measurements and discussion of NMR problems, Dr. H. Frauendorf and Mrs. G. Udvarnoki for MS and HR-MS measurements and helpful discussions of complicated cases, Mr. F. Hambloch for the elemental analysis, D. Ouw for the measurements of the fluorescence and absorption spectra, Nina Ohm for the measurements of some photophysical properties of the prepared compounds, Mr. Gerhard Busse for giving me the opportunity to work with very precise fluorimeter and help with the study of this equipment, Prof. Dr. D. Möbius for the assistance in work with the program Origin[®].

My thanks also go to Dr. Katrin Willig and Dr. Birka Lalkens for their help in the understanding of the basics of STED-nanoscopy.

I am very thankful to my colleagues Dr. Svetlana Polyakova and Dr. Gyuzel Mitronova for the invaluable “life experience” and “life wisdom”, their unquenchable optimism, which put me in a good mood in hard situations.

I thank Dr. V. Boyarskiy for his advice, support, scientific and historical discussions.

I am very grateful to all group members of the department of NanoBiophotonics, especially Dr. Vladimir Belov, Dr. Svetlana Polyakova, Dipl.-Chem. Roman Kunetsky, Prof. Dr. Mariano Bossi, Dr. Gyuzel Mitronova, Dipl.-Chem. Sevil Sejtablaeva, Dr. Kirill Kolmakov, Dr. Heiko Schill, Dr. Shamil Nizamov, Dr. Jan Marian von Hof and Dipl.-Chem. Maxim Sednev for their friendly laboratory atmosphere.

I would like to thank Dr. Kirill Kolmakov for the interesting scientific and historical discussions, for his moral support and for “tea-help” from Russia.

I appreciate the assistance and help from Mrs. Anja Dietrich, Ms. Josephine Stadler, Mrs. Sarah Aschermann, Ms. Alena Stefan and Mrs. Berta Hampel in the solving of many organizational problems in the course of my work and study.

My thanks go to the Otto-Hahn-Bibliothek-team at the Max-Planck-Institute and its head Bernard Reuse for the unlimited help with the search of scientific literature.

I am also very grateful to Mikhail Zhukovkiy, Denis Yalalov, Vadim Korotkov, Katya Zarudnaya, Sergey Korneev, Alexander Lygin, Antonina Lygina, Tanya Sergeeva, Mikhail Shaposhnikov, Mariana Balan, Chaytaniya Ullal, Valentin Rassadin, Alena Pan'kova, Alexey Galenko, Dmitrij Dar'in, Alexander Korolev for the friendship and moral support during the work in Göttingen, for the funny parties and nice trips to European countries during the free time.

I am very thankful to Dr. Pavel S. Lobanov for his moral support and faith in my abilities.

I thank Dr. Christian Wurm for his readiness to help in many biological questions and interesting scientific discussions.

I am very grateful to Dr. Heiko Schill, Dr. Kirill Kolmakov and especially Dr. Vladimir Belov for the careful proof-reading of this manuscript.

Dr. Heiko Schill and Dr. Marco Roose were of great help with all computer problems.

I thank Prof. Dr. Stefan W. Hell for financial support in my German courses at the Volkshochschule (VHS).

I am very grateful to my teachers at the VHS: Frau Krause, Tanya Vert, and University Dozent Alexandra Hensel for their great help and support in the study of the German language from the “zero”-level.

I appreciate the help from Dr. Heiko Schill in the correction of my German letters and documents, and finally,

my thanks also go to Hannes Bock for multiple discussions and the watching-together of many interesting soccer games.

Lebenslauf
