**Analysis of the RAB family of GTPases in  
*C. elegans* and their role in regulating  
neuronal membrane trafficking**

**PhD Thesis**

in partial fulfilment of the requirements  
for the degree “Doctor of Philosophy (PhD)”  
in the Neuroscience Program  
at the Georg August University Göttingen,  
Faculty of Biology

**Submitted by**

Nikhil Sasidharan

**Born in**

Attingal, India

2011

**I hereby declare that the PhD thesis entitled, “Analysis of the RAB family of GTPases in *C. elegans* and their role in regulating neuronal membrane trafficking”, was written independently and with no other sources and aids than quoted.**

**Göttingen, 14<sup>th</sup> March, 2011**

I. Abstract	1
<b>Chapter 1: Systematic analysis of the RAB GTPase family in <i>C. elegans</i></b>	<b>3</b>
II. Introduction	4
2.1 Intracellular transport is regulated by GTPases	4
2.2 Monomeric GTPases	6
2.3 Principles of Rab GTPase structure	8
2.3.1 The Rab GTPase fold	8
2.3.2 Structural insights on Rab-GAP interactions	10
2.3.3 Structural insights on Rab-GEF interactions	10
2.3.4 Structural insights on Rab-Effector interactions	11
2.3.5 Structural insights on Rab localization	12
2.4 Principles of Rab GTPase function	13
2.4.1 Rabs define sub-cellular compartments	13
2.4.2 Role of Rab GTPases in vesicle budding and uncoating	15
2.4.3 Role of Rab GTPases in vesicle motility	16
2.4.4 Role of Rab GTPases in vesicle tethering	17
2.4.5 Role of Rab GTPases in vesicle fusion	19
2.5 Integration of Rab function	19
2.5.1 Rabs form microdomains	19
2.5.2 Rab conversion cascades	21
2.5.3 Rab exclusion cascades	22
2.6 Cell-type specific functions of Rabs	22
2.7 Redundancy in Rab function	23
III. Aims	24
IV. Results	27
4.1 Expression pattern analysis of <i>C. elegans</i> RABs	27
4.2 Sub-cellular localization analysis of <i>C. elegans</i> RABs in neurons	30
4.3 Functional analysis of <i>rab</i> mutants	32
4.3.1 Movement analysis	34
4.3.2 Defecation motor program analysis	36
4.3.3 Egg-laying analysis	37
4.4 Pharmacological analysis of synaptic transmission	38
4.4.1 Aldicarb sensitivity	38
4.4.2 Levamisole sensitivity	40

4.5 Analysis of ciliated sensory neurons in <i>rab</i> mutants	41
4.5.1 DiI staining of amphids and phasmids	41
4.5.2 Analysis of amphid neuron function	43
4.5.3 Synthetic RNAi analysis of <i>rab</i> mutants	44
V. Discussion	46
5.1 The <i>C. elegans</i> genome encodes 28 differentially expressed RABs	46
5.2 Multiple RABs localize to the Golgi in neurons	48
5.3 RAB function in the <i>C. elegans</i> nervous system	48
5.3.1 Role of RABs in regulating simple behaviors	48
5.3.2 Role of RABs in regulating synaptic transmission	50
5.3.3 Role of RABs in regulating chemosensation	51
5.4 <i>C. elegans</i> RABs function redundantly together	52
<b>Chapter 2: Regulation of dense core vesicle secretion by RAB GTPases in <i>C. elegans</i></b>	<b>54</b>
VI. Introduction	55
6.1 The SV exocytosis machinery	55
6.2 The DCV exocytosis machinery	60
6.3 DCV biogenesis and maturation	60
6.4 DCVs function to regulate synaptic transmission	61
6.5 Studying DCV function in <i>C. elegans</i>	62
VII. Aims	65
VIII. Results	67
8.1 RAB-5 and RAB-10 are novel RABs essential for DCV release	67
8.2 DCV trafficking defects are autonomous to the nervous system	69
8.2.1 Development of a neuron-specific RNAi system	69
8.2.2 RAB-5 and RAB-10 cell-specifically regulate DCV release	70
8.3 Identification of RAB regulators involved in DCV release	71
8.4 RAB-5, TBC-2, RAB-10 and TBC-4 also affect secretion of INS-22	73
8.5 Endocytosis in coelomocytes is not affected	74
8.6 Synaptic vesicle release is not affected	74
8.6.1 Analysis of SV markers: SNB-1 and RAB-3	74
8.6.2 EM analysis of SV distributions in synapses	76
8.6.3 EM analysis of neuron morphology	78
8.6.4 Electrophysiological analysis of synaptic transmission	78
8.7 TBC-4 is a potential GAP for RAB-10	78
8.8 Rabaptin-5 bridges RAB-5 and RAB-10 function	82
8.9 EHBP-1 also regulates DCV release and interacts with RAB-10	84
8.10 Colocalization analysis of novel factors involved in DCV release	84
IX. Discussion	88
9.1 RAB-5 and RAB-10 are novel regulators of DCV secretion	88

## ABBREVIATIONS

aBoc	Anterior body contraction
ACh	Acetylcholine
AChE	Acetylcholinesterase
Arl	Arf-like
CaM	Calmodulin
CAPS	Ca <sup>2+</sup> -dependent activator protein for secretion
CC	Coiled coil
CCV	Clathrin coated vesicle
CH	Calponin homology
COG	Conserved oligomeric complex
COPI	Coat protein complex I
COPII	Coat protein complex II
DAG	Diacylglycerol
DBD	Dynactin binding domain
DCV	Dense core vesicle
DENN	Differentially expressed normal versus neoplastic
DGK	Diacylglycerol kinase
DNC	Dorsal nerve cord
ECM	Extra-cellular milieu
EEA-1	Early endosomal antigen-1
EGF	Epidermal growth factor
Emc	Enteric motor contraction
EPSC	Excitatory postsynaptic current
ER	Endoplasmic reticulum
ERGIC	ER-Golgi intermediate compartments
FGFR	Fibroblast growth factor receptor
FIP2	Rab11 family interacting protein-2
GABA	$\gamma$ -Aminobutyric acid
GAP	GTPase activating protein
GARP	Golgi associated retrograde protein complex
GDI	GDP dissociation inhibitor
GDP	Guanosine diphosphate
GEF	Guanine nucleotide exchange factors
GFP	Green fluorescent protein
GGTase	Geranylgeranyl transferase
GLUT4	Glucose transporter-4
GPCR	G-protein coupled receptor
GST	Glutathione-S-transferase
GSV	Glucose transporter-4 containing secretory vesicle
GTP	Guanosine triphosphate
HOPS	Homotypic vacuole protein sorting complex
HPF-EM	High pressure freeze-electron microscopy
HSN	Hermaphrodite specific neuron
iDCV	Immature dense core vesicle
IP <sub>3</sub>	Inositol (1,4,5) trisphosphate
IPTG	isopropyl $\beta$ -D-thiogalactopyranoside
M6P	Mannose-6-phosphate
M6PR	Mannose-6-phosphate receptors
MANNS	Mannosidase

MDCK	Madin-Darby Canine Kidney
mDCV	Mature dense core vesicle
nAChR	Nicotinic ACh receptor
NGM	Nematode growth medium

OCRL	Oculocerebrorenal syndrome of Lowe
ORP1L	Oxysterol-binding protein related protein 1L
pBoc	Posterior body contraction
PH	Pleckstrin homology
PIP <sub>2</sub>	Phosphoinositol (4,5) bisphosphate
PLC	Phospholipase C
PM	Plasma membrane
Rab	Ras genes from rat brain
RABN-5	Rabaptin-5
REP	Rab escort protein
RFP	Red fluorescent protein
RILP	Rab interacting lysosomal protein
SNAREs	Soluble N-ethylmaleimide-sensitive factor attachment protein receptors
SV	Synaptic vesicle
Syt-1	synaptotagmin-1
TBC	Tre-2/Cdc16/Bub2
TGN	Trans-Golgi network
TIP47	Tail-interacting protein of 47 kDa
TR-BSA	Texas-red conjugated to bovine serum albumin
TRAPP	Transport protein particle complex
VNC	Ventral nerve cord
VSV-G	Vesicular stomatitis virus glycoprotein
WT	Wild type
Y2H	Yeast-2-hybrid
YFP	Yellow fluorescent protein

## ACKNOWLEDGEMENTS

The last three and a half years have been an intensive, wonderful experience and there have been a number of individuals whom I must acknowledge for the part they played.

First I would like to thank Dr. Stefan Eimer for giving me the opportunity to work in his lab, for sharing his knowledge and his never-ending enthusiasm for science. Moreover, I am thankful for his supervision and introducing me to the field of *C. elegans* neurobiology.

I extend my gratitude to Prof. Dr. Nils Brose and Prof. Dr. Walter Stühmer for their interest, advices and suggestions during the thesis committee meetings. Furthermore, I am also grateful to Prof. Dr. Mikael Simons for agreeing to be an additional member of my thesis committee, for his excitement and advices during the course of the project

The Göttingen Graduate School for Neurosciences and Molecular Biosciences (GGNB) and Neurosciences coordination offices have helped me immensely through administrative work and also through assisting in the overall organization of the PhD. For this I am thankful to Prof. Dr. Michael Hörner, Dr. Steffen Burkhardt, Sandra Drube and Kirsten Poehlker. Being a recipient of the GGNB excellence fellowship, I further acknowledge the GGNB graduate school for financial support during the course of my PhD.

I am thankful to Dr. Jan Hegermann for electron microscopy experiments. Special thanks to Prof. Dr. Alexander Gottschalk for electrophysiology experiments and Prof. Dr. Barth Grant for discussions and sharing of reagents. I am also grateful to Dr. Aymelt Itzen for a lot of advice and suggestions in handling proteins. I must acknowledge Jonas Barth, Alejandro Mendoza and Aniket Ghosh for help during their internships and lab rotation projects. I am especially thankful to all the members of my lab for assisting me with experiments and pushing the Rab project forward.

Additionally I cannot forget to recognize the excellent technical assistance provided by Dr. Sabine Koenig and Katrin Schwarze.

I have never regretted any of my decisions because they have always led me into the company of good people. To Dr. Sumakovic, I am simply lucky to have had shared an office and a lab with you. Cloning, imaging, injections, coffee, cloning, imaging, injections, coffee, coffee and a little bit of SDS gel on the side. I loved it all. To Mandy, thank you for being exactly the person that was missing in our office. I am thankful also for all the bowling, and the table tennis games (I will win 1 day!!!) and more importantly for teaching an Indian what it means to be German. I am also thankful to the other members of our lab: Christian Olendrowitz, Nora Wender, Ling Luo and Maike Kittelmann for creating a friendly atmosphere and for their support.

I am thankful to the other members of my batch: Ramya Nair, Raunak Sinha and Dr. Chou-hua Huang for their friendship. I also acknowledge, Dr. Shahaf Peleg for his friendship, making me laugh and for the many schnitzel sessions.

I am particularly thankful to my flat mate Dr. Peer Hoopmann for agreeing to live with me, which is not an easy decision to make. I enjoyed it all. There is always going to be some food waiting for him on Saturdays.

I am also thankful to my buddies Sagar Bora, Eugen Nacu, Tadas Jucikas and Andrew Jack Knott for their friendship, and for their constant willingness to help wash clean my brain.

And last I would like to thank my bebek, for making every day more beautiful.

**Dedicated to my parents and my brother Rinosh,  
for their constant love and support**

## I. ABSTRACT

Rab GTPases are master regulators of intracellular trafficking. They are involved in every aspect of membrane transport from vesicle budding to vesicle fusion. Their functions are regulated by guanine nucleotide exchange factors (GEFs) and GTPase activating proteins (GAPs). The mammalian genome encodes over 60 different Rab proteins. Each of these Rabs localizes to specific compartments. The actions of multiple Rabs are coordinated through Rab cascades where a single Rab recruits the machinery to activate or inactivate a secondary Rab. Considering the large Rab family size, very little is known about the majority of its members and how they work together.

As opposed to the human system, the *C. elegans* RAB family encodes 28 members with normally just one isoform per Rab member. The smaller Rab family size, together with the genetic tractability of *C. elegans* allowed for a broad-scale analysis of each RAB protein. For this analysis it was decided to initially determine the expression pattern and sub-cellular localization of all *C. elegans* RABs. Expression pattern analyses revealed that *C. elegans rabs* are differentially expressed with a pattern of preference for the nervous system. Additionally, the sub-cellular localization analysis of the Rabs showed that they localize to specific sub-cellular compartments with many displaying partial staining to the Golgi apparatus. The availability of mutants for 90% of the *rabs* in *C. elegans* further provided the opportunity to elucidate novel RAB functions. Since most RABs were neuronally expressed, all *rab* mutants were tested for changes in a set of nervous system mediated behaviors: movement, defecation motor program, and egg laying. Analysis revealed that several RABs are important regulators of these behaviors. Additionally all *rab* mutants were also tested for defects in synaptic transmission through sensitivity to aldicarb. Several new RABs were identified to modulate aldicarb sensitivity. Mutant analysis showed that although several *rab* mutants displayed

phenotypes of nervous system dysfunction, the majority of animals were healthy. This suggested that many RABs function redundantly together in *C. elegans*. To elucidate which RABs cooperate together, a synthetic RNAi screen was conducted where each *rab* mutant was co-depleted with the remaining 27 Rabs. Co-depletion of multiple *rabs* has provided novel insights into the higher order RAB network.

In the second chapter of this study, we aimed to identify novel RABs involved in dense core vesicle (DCV) signaling. Interestingly *rab-5* and *rab-10* mutants showed defects in DCV secretion. Additionally, two TBC (Tre-2/Cdc16/Bub2) domain-containing molecules, TBC-2 and TBC-4, were identified to function as potential GAPs for RAB-5 and RAB-10 respectively. Lastly we have identified an interaction between a RAB-5 effector, Rabaptin-5 (RABN-5), and TBC-4, which provides a link between RAB-5 and RAB-10 function. Taken together, these results suggest the existence of a novel Rab exclusion cascade in the regulation of DCV release, where active RAB-5 recruits TBC-4 for the local inactivation of RAB-10.

# **CHAPTER 1:**

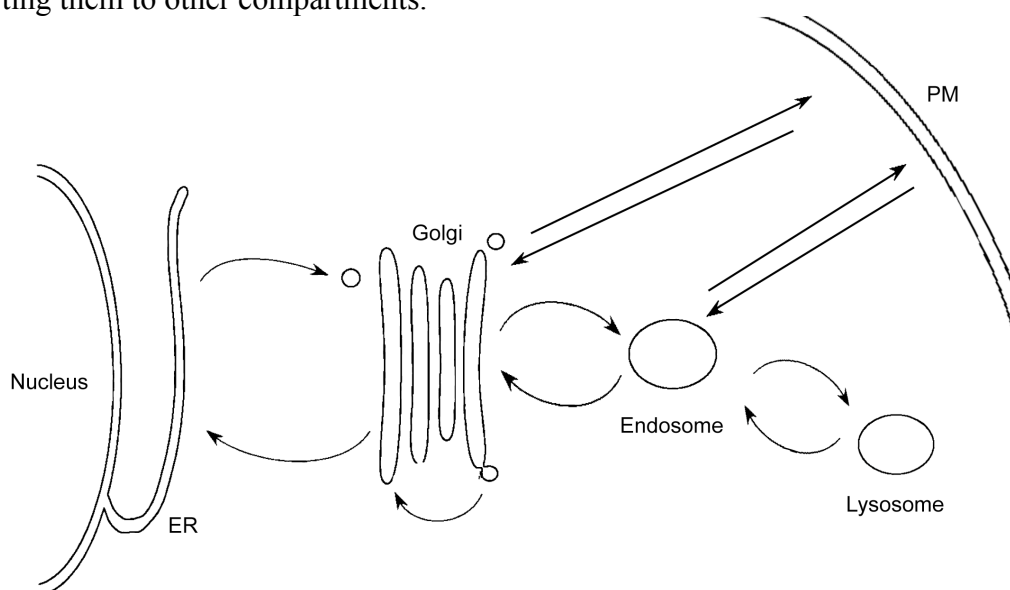

## **SYSTEMATIC ANALYSIS OF THE RAB GTPASE FAMILY IN *C. ELEGANS***

## II. INTRODUCTION

### 2.1 Intracellular transport is regulated by GTPases

Eukaryotic cells are defined by their compartmentalized endo-membrane system. As opposed to prokaryotes, these cells evolved the ability to organize biomolecules to form sub-cellular organelles, such as the endoplasmic reticulum (ER), the Golgi apparatus, endosomes and lysosomes (Fig. II.1). Each organelle is membrane-bound, spatially segregated and specialized to carry out a particular function. The ER serves as a center to synthesize membrane proteins, lysosomal hydrolases and proteins destined for secretion (Alberts et al., 2008). The Golgi acts as a sub-cellular hub by receiving proteins from one compartment, processing them and sorting them to other compartments.

**Figure II.1. The major sub-cellular compartments of eukaryotic cells.** Eukaryotes have membrane bound compartments, which carry out specific functions.: ER, Golgi, Endosomes, Lysosomes. Proteins and membrane are continuously transported between these compartments and to the plasma membrane (PM). Source: Picture taken and adapted from Oka and Krieger, 2005.

It is a polarized structure composed of multiple cisternae with the early cis-faced cisternae oriented towards the ER and the late trans-faced cisternae oriented away from the ER (Lowe, 2010; Glick and Nakano, 2009). Endosomes and lysosomes are cellular stations for recycling and degradation of biomolecules (Seaman, 2008; Alberts et al., 2008). Each compartment also maintains a highly specialized microenvironment to facilitate their functions. For example the ER has a highly oxidizing environment, which allows disulfide formation during protein folding and endosomes / lysosomes are acidic allowing for efficient function of degradative enzymes called hydrolases (Alberts et al., 2008).

The transport of proteins between these organelles is organized by membrane-bound vesicles. There are four essential steps in vesicle transport: vesicle budding from a donor compartment, vesicle motility, vesicle tethering and vesicle fusion to a target compartment (Fig II.2.). These processes demand the coordinated effort of a cohort of proteins: coat proteins, molecular tethering factors, monomeric guanosine nucleotide triphosphatases (GTPases) and soluble N-ethylmaleimide-sensitive factor attachment protein receptors (SNAREs) (Cai et al., 2007). Among these factors, monomeric GTPases have emerged as the major regulators due to their involvement in all steps of vesicular transport (Segev, 2011).

**Figure II.2. Vesicular transport between organelles occurs in four distinct steps.** Vesicles bud from the donor compartment through the recruitment of coat proteins (COPI, COPII and Clathrin). Cargo proteins are then loaded into newly formed vesicles and transported to the acceptor compartment via motor proteins. Upon arrival, vesicles are tethered to the acceptor compartment and subsequently undergo fusion. Monomeric GTPases of the Arf/Sar, Rho, Dynamin and Rab families control and regulate each of these steps. (Cai et al., 2007; Donaldson and Segev, 2009). Source: picture taken and adapted from Segev, 2011.

## 2.2 Monomeric GTPases

Four major families of GTPases function to regulate intracellular transport: the Arf/Sar family, the Rho family, the Dynamin family and the Rab family (Donaldson and Segev, 2009; Itzen and Goody, 2011). The hallmark of these GTPases is that they act as molecular switches cycling between an active guanosine nucleotide triphosphate (GTP)-bound form and an inactive guanosine nucleotide diphosphate (GDP)-bound form (Fig. II.3). With the exception of dynamin, these GTPases require accessory enzymes named guanine nucleotide exchange factors (GEFs) to catalyze the exchange of GDP to GTP and GTPase activating proteins (GAPs) to catalyze the hydrolysis of GTP to GDP (Hinshaw, 2000; Itzen and Goody, 2011). In the active GTP-bound form, GTPases bind to a multitude of effector proteins (Takai et al., 2001). The complex array of GTPase-effector interactions allows them to participate at multiple steps in vesicular transport.

The Arf/Sar family of small GTPases (~ 20 kDa) is composed of 7 members: Arf1-Arf6 and Sar1. Members of this family are structurally distinguished by the presence of an N-terminal amphipathic helix. Normally buried, this helix is exposed upon binding to GTP allowing for localization to membranes (Gillingham and Munro, 2007). Most members of the Arf family are additionally myristoylated at the N-terminus (Wennerberg et al., 2005). These proteins are best characterized for their role in vesicle budding at the ER-Golgi interface. Arf1 localization to the Golgi leads to the recruitment of coat protein complex I (COPI) and facilitates membrane deformation during vesicle budding (Pucadyil and Schmid, 2009). In contrast to Arf1, Sar1 localizes to the ER and recruits components of the coat protein complex II (COPII) also facilitating membrane deformation during budding at ER exit sites. Furthermore, members of the Arf family have been proposed to act as timers promoting disassembly of COP coats post-vesicle budding (Barlowe et al., 1994; Gillingham and Munro, 2007).

The Rho family of small GTPases are composed of 3 members: RhoA, Rac and CDC42. Rho GTPases all share a conserved –CAAX motif at the C-terminus, which serves as a site for isoprenylation (Hakoshima, 2003). Once activated, this lipid modification allows Rho proteins to localize to membranes. Rho GTPases are involved in regulating many processes, but their best-documented role is in

**Figure II.3. Regulation of vesicular transport by GTPases.** **A.** Four major GTPase families regulate vesicular transport: The Arf/Sar, Rho, Dynamin and Rab families. **B.** All GTPases cycle between an active GTP-bound form and an inactive GDP-bound form. Since most monomeric GTPases have slow intrinsic rates of GDP release and GTP hydrolysis they require the assistance of GEFs and GAPs to catalyze these reactions. (Goody and Hoffman-Goody, 2002). Pi: Inorganic phosphate

regulating actin dynamics within the cell. Rac GTPases stimulate the formation of plasma membrane extensions called lamellipodia, Cdc42 regulates the formation of finger-like protrusions called filopodia and Rho controls the formation of actin bundles such as stress fibers (Nobes and Hall, 1995). Constitutively active and inactive mutants of Rho GTPases also show defects in clathrin-mediated endocytosis of transferrin and epidermal growth factor (EGF) suggesting its role in vesicular transport (Lamaze et al., 1996). It has been proposed that this effect of Rho GTPases

on endocytic trafficking is mediated via its modulation of the actin network. However, the precise mechanisms of such a function remains unknown (Symons and Rusk, 2003).

The dynamin family of GTPases is composed of 3 members: Dynamin 1-3. As a GTPase family, they are relatively large proteins (~ 100 kDa) that are composed of several domains: a GTP hydrolysis domain, a middle domain, a pleckstrin homology domain for membrane localization, a GTPase effector domain and a C-terminal proline-rich domain (Low and Löwe, 2010). Unlike the small GTPases, dynamins have high rates of intrinsic GTPase activity. This relieves them from the need for GAPs to regulate their function (Hinshaw, 2000). Once activated, they polymerize around the necks of newly budded vesicles and assist mainly in the pinching reaction that separates newly formed vesicles from the donor compartment (Hinshaw, 2000).

With over 60 members encoded in the human genome, the Rab family is by far the largest family of GTPases (Pereira-Leal and Seabra, 2001). Most Rabs have also been shown to localize to specific compartments creating the idea that they give identity to these compartments. Together with the fact that each Rab binds a vast number of effector proteins, this has raised much interest in unraveling their potential role as the master regulators of intracellular transport (Zerial and McBride, 2001).

## 2.3 Principles of Rab GTPase structure

### 2.3.1 The Rab GTPase fold

Being a sub-group of the Ras superfamily of GTPases, Rab proteins share the common GTPase fold consisting of six  $\beta$ -sheets ( $\beta$ 1-6) and five  $\alpha$ -helices ( $\alpha$ 1-5). Rabs start at the N-terminus with a distinct GxxxxGK(S/T) motif named the P-loop (loop between  $\beta$ 1 $\alpha$ 1), which is important for binding phosphate and coordinating  $Mg^{2+}$ . The GTPase fold additionally contains two switch regions (switch I and switch II), which stabilize the  $\gamma$ -phosphate of GTP (Hutagalung and Novick, 2011). In the GDP bound state, the switch regions are disordered, but upon GTP binding they undergo a conformation change to an ordered state (Fig II.4). This active conformation of the switch regions varies largely between Rabs and is thought to contribute towards functional specificity, along with the interswitch region and the

**Figure II.4. Detailed structure of Rab GTPases.**

**A.** Schematic representation of the secondary structure of the Rab GTPase: Rab5A. The switch (green) / interswitch (red) regions and  $\alpha\beta^5$  loop are important for Rab-Effector interactions. The hydrophobic triad (F57, W74 and Y99) are enlarged and underlined. The hypervariable region (purple) and the C-terminal cysteines are needed for localization (Hutagalung and Novick, 2011). **B.** Tertiary structure of the Rab5A bound to GDP and the non-hydrolyzable GTP analogue (GppNHp). Upon GTP binding, the switch I and switch II regions enter an ordered state (Lee et al., 2009). **C.** Scheme of a Rab protein attached to a membrane via its geranylgeranyl group. Source: Crystal structure of Rab5A-GDP and GppNHp (B) were taken and adapted from Zhu et al., 2004; Terzyan et al., 2004. Scheme of Rab bound to membrane (C) was taken and adapted from Gillingham and Munro., 2007.

$\alpha 3\beta 5$  loop (Lee et al., 2009). An individual Rab protein binds its cognate GAP, GEF and effector proteins via these distinct motifs (Itzen and Goody, 2011).

### 2.3.2 Structural insights on Rab-GAP interactions

RabGAPs stimulate the rate of GTP hydrolysis of Rabs. They are defined by a characteristic TBC (Tre-2/Cdc16/Bub2) domain. Over 40 members have been identified in the human genome (Fukuda, 2011). The crystal structure of the yeast GAP, Gyp1p, in complex with the mammalian GDP-Rab33-AIF<sub>3</sub> revealed that IxxDxxR and YxQ motifs of GAPs contribute to GTP hydrolysis through a dual-finger mechanism. Mutation of either the arginine or glutamine finger to alanine abolishes GAP activity (Pan et al., 2006). Unlike other small GTPases, the DxxGQ motif of switch II is not thought to participate directly in the catalysis by RabGAPs, but instead binds at another site on the GAP backbone (Fig II.5) (Pan et al., 2006). Although, the catalytic mechanism of GAP action has been elucidated, it is not fully clear how Rabs recognize their cognate GAPs.

**Figure II.5. Structure of a Rab-GAP complex in its transition state.** **A.** Overview of the Gyp1p-GDP-Rab33 complex in the presence of the transition state mimetic AIF<sub>3</sub>. **B.** Selected view of the active site of the complex displaying the catalytic IxxDxxR and YxQ motifs of Gyp1p. The arginine and the glutamine residues make contact with AIF<sub>3</sub>, whereas the glutamine of the DxxGQ motif from Rab33 does not. Source: Picture is taken from Pan et al., 2006.

### 2.3.3 Structural insights on Rab-GEF interactions

RabGEFs catalyze the exchange of GDP to GTP by increasing the rate of GDP dissociation of Rabs. In addition, it has also been shown that they contribute to Rab

localization by locally activating and concentrating them (Schoebel et al., 2009). To date, approximately 25 RabGEFs have been identified to be encoded by the human genome (Barr and Lambright, 2010). However, in contrast to RabGAPs, there is no major consensus domain for RabGEFs making it difficult to identify them. They exist in many shapes and sizes: Vps9-domain containing GEFs such as Rabex5, the GEF for Rab5, operate by binding to the switch/interswitch regions, opening switch I and inserting an aspartate finger to destabilize the  $Mg^{2+}$  / phosphate binding sites (Itzen and Goody, 2011). Coiled coil domain containing GEFs such as Sec2, found in yeast, act on the Rab GTPase Sec4, through a similar mechanism of binding to the switch/interswitch region and distorting switch I (Barr and Lambright, 2010). Recently a third group of DENN (differentially expressed normal versus neoplastic) domain containing GEFs have been discovered, however their mechanism of action remains unclear. It is likely that they also function via switch I displacement (Barr and Lambright, 2010; Sato et al., 2008; Yoshimura et al., 2010).

### 2.3.4 Structural insights on Rab-Effector interactions

Rab proteins bind a plethora of structurally unrelated effector proteins to carry out downstream functions. Much of the structural data available on Rab-Effector interactions suggest that the interaction interface occurs between one or two alpha-helices / coiled coils of an effector and the switch/interswitch/ $\alpha\beta\gamma$  loop of the Rab as seen with Rab3A-Rabphilin-3A, Rab4-Rabenosyn-5, Rab5A-Rabaptin-5C, Rab6-GCC185, Rab7-RILP and Rab11-FIP2 (Ostermeier and Brunger, 1999; Eathiraj et al., 2005; Zhu et al., 2004; Burguete et al., 2008; Jagoe et al., 2006; Wu et al., 2005). Some of these structures are depicted in Figure II.6. Interestingly, all Rab-Effector interactions demand the requirement of a conserved hydrophobic triad of residues: a phenylalanine at the beginning of the interswitch region, a tryptophan in the second half of the interswitch region and a tyrosine at the end of switch II (shown for Rab5A in Fig.II.4). Among these residues, the phenylalanine helps coordinate  $Mg^{2+}$ , while the tryptophan and tyrosine interact directly with the effector protein (Itzen and Goody, 2011).

Currently only a fraction of Rab-effector complexes have been crystallized. From genetic and biochemical studies, it is clear that rabs also bind to cargo molecules, kinases, phosphatases, motor proteins and large multi-subunit tethering

**Figure II.6. Variations in Rab-Effector complexes.** Crystal structures of Rab3A-Rabphilin-3A, Rab4-Rabenosyn-5 and Rab5A-Rabaptin-5C are depicted along with magnification of the interaction interface between effector (orange/pink) and switch/inter-switch (blue) regions. The effector residue for Rab binding is circled. The hydrophobic triad residues of the Rab are underlined. **A.** Rabphilin-3A interacts with Rab3 through a single alpha helix motif. **B.** Rabenosyn-5 interacts with Rab4 through a helix-turn-helix motif and **C.** Rabaptin-5C interacts with Rab5A through a homodimeric coiled coil with the stoichiometric ratio of 2 coils : 2 Rab5 molecules (only one Rab5A molecule shown). Source: Pictures taken and adapted from Kawasaki et al., 2005.

complexes (Grosshans and Novick, 2006; Guo et al., 1999; Siniosoglou and Pelham, 2002). However, the nature of these interactions remains to be understood at atomic resolution.

### 2.3.5 Structural insights on Rab localization

Downstream of the switch regions necessary for GAP, GEF and effector interactions, is a C-terminal hypervariable region (Fig II.4). The hypervariable region of a Rab is the most divergent part of its structure and has hence been proposed to act as a targeting signal (Chavrier et al., 1991). Recent evidence has suggested that the localization of Rabs is more complex and dependent on other elements of its structure as well as on its interaction with effectors (Ali et al., 2004; Schoebel et al, 2009). Lastly, the C-terminus of rab proteins contains a characteristic cysteine motif (CC, CXC, CCX, CCXX or CCXXX), a target for geranylgeranylation. *De novo*

**Figure II.7. Role of REP, RabGGTase and RabGDI on Rab localization.** REP, RabGGTase and RabGDI are additional factors, which contribute to the localization and function of Rabs. Newly synthesized Rabs are recognized by REP and delivered to the RabGGTase for prenylation. After prenylation, they are inserted into the donor compartments. A simplistic model suggests that upon activation by RabGEFs and interaction with effectors they mediate vesicular transport to an acceptor compartment. At the acceptor compartment Rabs are inactivated by RabGAPs. Upon inactivation, RabGDIs scoops GDP bound Rabs out of the acceptor compartment and deliver them back to the donor compartment (Hutagalung and Novick, 2011).

synthesized Rabs are recognized by Rab Escort Protein (REP) and taken to the rab geranylgeranyl transferase (RabGGTase) where these cysteine residues are lipid modified. After modification REP escorts the prenylated Rab to its appropriate compartment (Wennerberg et al., 2005). Once inactivated, a molecule structurally similar to REP named Rab GDP dissociation inhibitor (GDI) is necessary to recycle GDP bound Rabs to their original compartments (Fig. II.7) (Hutagalung and Novick., 2006).

## 2.4 Principles of Rab GTPase function

### 2.4.1 Rabs define sub-cellular compartments

One of the distinguishing features of Rab GTPases is that they provide a blueprint of all major sub-cellular compartments. The following are several examples: Rab1 localizes to ER-Golgi intermediate compartments (ERGIC), Rab2/Rab6/Rab33

**Figure II.8. Rabs localize to a variety of compartments.** There are over 60 rabs encoded in the human genome. Most of these Rabs localize to specific compartments and regulate the transport of membrane and proteins from a donor compartment to an acceptor compartment. Often a single Rab has multiple localizations depending on the tissue that it is expressed. Source: Picture taken from Stenmark, 2009.

to the Golgi, Rab9 to the TGN (trans-Golgi network), Rab3/Rab27 to synaptic vesicles, Rab8 to the basal bodies, Rab10, Rab11 and Rab35 to recycling endosomes, Rab5 to early endosomes, Rab7 to late endosomes, and Rab18 to lipid droplets etc. (Figure II.8) (Babbey et al., 2006; Fischer von Mollard et al., 1990; Kouranti et al., 2006; Meresse et al., 1995; Nachury et al., 2007; Ozeki et al., 2005; Stenmark et al., 1994; Ullrich et al., 1994; Stenmark, 2009). Furthermore, the localizations of Rabs can differ between cell-types adding an additional level of complexity. For example, Rab10 localizes to Golgi/ endosomes in Madin-Darby Canine Kidney (MDCK) cells, to cilia in renal epithelial cells, to glucose transporter 4 storage vesicles (GSVs) in adipocytes and to synaptic vesicles (SVs) in hippocampal neurons (Schuck et al.,

2007; Babbey et al., 2006; Babbey et al., 2010; Larance et al., 2005; Sano et al., 2008; Pavlos et al., 2010). These diverse and intricate patterns of sub-cellular localizations allow Rabs to regulate all steps of intracellular trafficking ranging from budding to fusion.

#### **2.4.2 Role of Rab GTPases in vesicle budding and uncoating**

As described previously, vesicle budding is primarily controlled by the Arf GTPase family. However, there are certain cases where Rabs take on specific roles. Lysosomal hydrolases are synthesized in the ER and transported via the secretory pathway to lysosomes. In order for these enzymes to reach the destination, they must undergo an N-linked mannose-6-phosphate (M6P) attachment at the Golgi. Once modified, the hydrolases are recognized by M6P receptors, which transport the hydrolases to endo-lysosomes, release them and recycle back (Alberts et al., 2008). The recycling of M6P receptors back to the Golgi was found to be mediated by a cytosolic protein named tail-interacting protein of 47 kDa (TIP47), which binds the receptors on their cytosolic domain (Diaz and Pfeffer, 1998). Interestingly, Rab9 was found to bind TIP47 leading to a model where Rab9 acts as an initiator of vesicle formation for M6P receptor recycling (Carroll et al., 2001).

Another example of Rabs participating in vesicle formation is seen through the interaction of Rab7 with the retromer complex. The retromer is involved in the transport of cargo from endosomes to the Golgi. It consists of sorting nexins and the Vps26-Vps29-Vps35 trimer, which binds directly to cargo (Seaman et al., 1998). The trimer is an effector of Rab7. Depletion of Rab7 leads to the disassembly of retromer and defects in endosome to Golgi trafficking (Rojas et al., 2008).

Newly budded vesicles must shed their coats (COP I, COPII or clathrin) upon budding to allow for competent fusion to an acceptor compartment (Hutagalung and Novick, 2011). Recently, a new role of Rab5 in clathrin uncoating was established. During clathrin coat formation, the clathrin adaptor protein, AP2, is recruited to membranes containing phosphatidylinositol-4,5-bisphosphate (PIP<sub>2</sub>) (Owen, et al., 2004). Upon recruitment, the  $\mu$ 2 subunit of AP2 is phosphorylated by a  $\mu$ 2 kinase (AAK1). Kinase activity is required for cargo recruitment (Jackson et al., 2003). After clathrin coat formation, a Rab5 GEF named hRme-6 displaces AAK1 leading to

decreased levels of phospho- $\mu$ 2. This is likely to occur through the activation of Rab5 and recruitment of an effector with phosphatase activity (Semerdjieva et al., 2008).

### 2.4.3 Role of Rab GTPases in vesicle motility

Vesicles are transported from the donor compartment to the acceptor compartment through the cellular cytoskeleton. In yeast, the Rab, Ypt31/Ypt32, localizes to the Golgi and to Golgi derived secretory vesicles. It has been shown that Ypt31/Ypt32 interacts directly with the type V myosin motor, Myo2. Since Myo2 is an actin-based motor, this interaction allows Golgi derived vesicles to move, via the actin cytoskeleton, towards the plasma membrane tip of budding yeast cells (Lipatova et al., 2008). Although, initially the transport of these vesicles was thought to be mediated by the Rab, Sec4, a direct interaction between Sec4 and Myo2 remains to be elucidated (Wagner et al., 2002). Mammalian Rabs have also been shown to regulate vesicle motility, albeit through indirect interactions with motors. Rab11 binds to the C-terminus of an effector called FIP2 (Rab11 family interacting protein-2). FIP2 consequently binds myosin Vb at a site closer to its N-terminus. This ternary complex is suggested to be important for vesicular transport from recycling endosomes to the plasma membrane (Hales et al., 2002). Similarly, Rab27 also interacts with myosin

**Figure II.9. Rabs interact with motor proteins.** In melanocytes, Rab27 localizes to lysosome related organelles named melanosomes. Melanosomes contain the pigment melanin, which protects skin cells against UV radiation. Melanosomes are trafficked to the cell periphery via an indirect interaction of Rab27a with the myosin Va motor protein. This interaction is mediated through the synaptotagmin-like protein, melanophilin (Fukuda et al., 2002). Source: picture taken and modified from Wu et al., 2002.

Va, through an adaptor protein named melanophilin to regulate the transport of melanosomes to the cell periphery (Fig II.9) (Wu et al., 2002). Mutations in Rab27, myosin Va and melophilin are associated with Griscelli syndrome a pigmentary disorder of the skin resulting from perturbed melanin trafficking (Menasche et al., 2000; Van Gele et al., 2009).

Rab mediated motility is not restricted to the actin cytoskeleton. Several Rabs have also been shown to interact with the microtubule motor proteins: kinesin and dynein / dynactin complex. Rab6 binds to the kinesin-like motor Rabkinesin-6 to regulate intra-Golgi transport (Echard et al., 1998). Rab7 interacts indirectly to dynein / dynactin via forming a complex with Rab-interacting lysosomal protein (RILP) and oxysterol-binding protein-related protein 1L (ORP1L) complex (Johansson et al., 2007). Interestingly, certain pathogens such as *Salmonella enterica* prevent RILP recruitment by Rab7 to modulate endo-lysosomal trafficking while entering host cells (Harrison et al., 2004).

#### **2.4.4 Role of Rab GTPases in vesicle tethering**

Specificity and directionality in vesicular transport is mediated by highly regulated tethering of vesicles to the acceptor compartment. Among all roles of Rab GTPases in vesicular transport, its role in vesicle tethering is by far the most pronounced. Rabs bind to two major classes of tethering factors: long coiled-coil proteins and large multisubunit protein complexes.

Golgins are the most prominent member of the long coiled-coil class of proteins. Golgins localize to distinct Golgi cisternae and are thought to form a proteinaceous meshwork surrounding it (Yu and Hughson, 2010). They extend long homodimeric-coiled coils away from the Golgi membrane, which serve as sites for Rab GTPase binding. Additionally they typically have C-terminal GRIP/GRAB domains, which are recognized by Arf and Arl (Arf-like) GTPases (Ramirez and Lowe, 2009). A model for the interaction of the TGN-localized Golgin, GCC185 with both GTPases was recently published (Fig. II.10) (Burguete et al., 2008). The precise sequence of events, which takes place, still remains elusive. The most recent hypothesis of Golgin function, suggests that they are targeted to the Golgi through the interaction of their GRIP domains with Arfs and that they use their coiled coil domains as tentacles to tether incoming vesicles by contacting Rab GTPases (Sinka et al., 2008).

**Figure II.10. Model for tethering by Golgins.** **A.** Since Golgins form a meshwork around the Golgi and because they harbor multiple binding sites for Rabs, it is currently believed that they behave like tentacles attracting incoming vesicles from donor compartments. Golgins contain N-terminal GRIP domains, which bind Arfs and C-terminal coiled coils, which bind Rabs. (Yu and Hughson, 2010) **B.** A model of the entire Rab6-GCC185-Arl1 complex based on the crystal structures of Rab6-GCC185 and Arl1-GCC185. Source: Pictures taken from Yu and Hughson, 2010; Burguete et al., 2008.

There are seven conserved multisubunit tethering complexes identified: COG (conserved oligomeric complex), CORVET, Dsl1, exocyst, GARP (Golgi associated retrograde protein complex), HOPS (homotypic vacuole protein sorting) and TRAPP (Transport protein particle complex) (Cai et al., 2007). Among these complexes, several have been shown to interact with Rabs. One of the first large multisubunit complex – Rab interaction was identified in yeast between Sec4 and the Sec15 subunit of the exocyst. This interaction is important for vesicle tethering and polarized exocytosis at the bud tip (Guo et al., 1999). Furthermore, in yeast, a subunit of COG interacts with the GTPase Ypt1p as well as the COPI coat to regulate recycling of Golgi resident enzymes to their rightful cisternae (Suvorova et al., 2002; Hutagalung and Novick, 2011). The Vps52 subunit of the GARP also interacts with Rab6 to regulate retrograde transport from the endosomes to Golgi (Liewen et al., 2005; Siniosoglou and Pelham, 2001). Unlike other complexes, the TRAPP and HOPS complexes act as GEFs for Rab1 and Ypt7p (yeast orthologue of Rab7) respectively (Yamasaki et al., 2009; Wurmser et al., 2000). However, it must be mentioned that the claim of HOPS mediated GEF activity on Ypt7p is a subject of recent controversy (Nordmann et al., 2010). It has also been suggested that CORVET may act as a GEF on Vps21 (yeast orthologue of Rab5) (Peplowska et al., 2007).

### 2.4.5 Role of Rab GTPases in vesicle fusion

SNAREs were believed to form the minimal machinery necessary for vesicle fusion. *In vitro*, the neuronal SNAREs; Synaptobrevin-2, SNAP-25 and syntaxin-1, were shown to autonomously fuse membranes. However, these reactions displayed slow kinetics (half-life of 10 minutes) and required relatively high concentrations of SNAREs (mg range) (Weber et al., 1998). Since, *in vivo*, these reactions occur in the sub-millisecond time scale and given that as few as 3 SNARE complexes are needed for fast vesicle fusion, it is conceivable that additional factors are necessary for efficient neuronal membrane fusion (Katz et al. 1969; Mohrmann et al., 2010). Interestingly, in line with this argument, two recent studies have already provided evidence for the integral role of Rabs in endo-lysosomal homotypic fusion. Rab5 and its effectors, Rabenosyn-5 and Rabaptin-5, have been shown to be essential for synthetic endosomes fusion bearing endosomal SNAREs (Ohya et al., 2009). The yeast orthologue of Rab7, Ypt7p, and its GEF, the HOPS complex are necessary to drive fusion of proteoliposomes bearing yeast vacuolar SNAREs (Stroupe et al., 2009). It is important to note that even though Rabs are essential for fusion, it is likely through their interactions with tethering factors that they increase the efficiency and specificity of SNARE driven vesicle fusion.

## 2.5 Integration of Rab function

Although many Rabs have been shown to localize to distinct compartments for their functions, it is clear that the number of Rabs far exceed the number of cellular compartments. This leads to multiple Rabs localizing to the same compartment. This phenomenon has brought forth the concept of the fine localization of Rabs to microdomains and the maturation of these domains via Rab cascades (for a recent review see Stenmark, 2009).

### 2.5.1 Rabs form microdomains

Pioneering studies from Zerial and colleagues, showed, for the first time, that Rab4, Rab5 and Rab11 localize to distinct domains on endosomes (Sönnichsen et al., 2000). Early endosomes predominantly consist of Rab5 and Rab4 domains, with few Rab11 domains, whereas recycling endosomes contain mostly Rab4 and Rab11

**Figure II.11. Rabs localize to microdomains.** It has been shown that Rab proteins, which localize to the same compartment, often exist in microdomains. This is seen with Rab4 and Rab5, which localize to microdomains on early endosomes. It is also evident with Rab11 and Rab4 on recycling endosomes. Source: Picture taken from Sönnichson et al., 2000.

domains (Fig. II.11) (Sönnichson et al., 2000). Through results from transferrin recycling assays, it was shown that newly endocytosed transferrin accumulates in Rab5-Rab4 positive compartments and then upon saturation enters the Rab11-Rab4 positive compartments (Sönnichson et al., 2000).

In an independent study, it was also revealed that Rab9 and Rab7 localize to distinct microdomains on late endosomes. It is believed that Rab9 positive microdomains function in M6P receptor recycling to the Golgi, whereas the Rab7 microdomains continue on to undergo homotypic fusion (Barbero et al., 2002). Although it must be mentioned that a recent study established a role for Rab7 also in M6P receptor recycling to the Golgi via an interaction with retromer (Rojas et al., 2008). However, it is believed that there are two pools of Rab7, one pool of Rab7 localized at the early endosomes in the proximity of Rab5 and another pool of Rab7 localized at the late endosomes in the proximity of Rab9, which would explain these conflicting data.

### 2.5.2 Rab conversion cascades

The existence of microdomains allows for the spatial segregation of Rabs on a single compartment. This, in turn, permits efficient sorting of cargos. Recently, it has come to light that an individual Rab-microdomain can temporally mature into another Rab-microdomain. This gives rise to the idea of compartmental maturation by Rab cascades. Rab conversion is a type of cascade where an individual Rab recruits the GEF of a secondary Rab thereby activating it and initiating the next trafficking step (Figure II.12) (Stenmark, 2009). Such cascades are thought to provide directionality in trafficking.

The first Rab conversion was described, in yeast, between the GTPases; Ypt31/32 and Sec4. Ypt32/31 localizes to the late Golgi. However, as secretory vesicles form at the TGN, Ypt32/31 recruits Sec2. Sec2 is a GEF, which subsequently recruits and activates its substrate Sec4. Sec4 labeled secretory vesicles then move towards their acceptor membrane (Ortiz et al., 2002). A second Rab conversion between Rab5 and Rab7 has also been elucidated. Early Rab5 positive endosomes recruit the HOPS complex through an interaction between Rab5 and Vps41 (a subunit of HOPS). Vps39, another subunit of HOPS harboring GEF activity, is thought to recruit and activate Rab7 allowing for maturation of early endosomes into late endosomes (Rink et al., 2005). Recently a new complex named, Mon1-Ccz1 has been implicated in this conversion. Interestingly Mon1-Ccz1 binds and displaces Rabx5 (GEF for Rab5) and in parallel binds to the Vps39 subunit of HOPS, perhaps contributing to the fidelity of this conversion (Poteryaev et al., 2010; Nordmann et al., 2010).

**Figure II.12. Model of a Rab conversion cascade.** Rabs label compartments and as one compartment matures into another compartment, a specific label is exchanged for another through Rab cascades. Rab conversion occurs when an upstream Rab recruits the GEF of a downstream Rab. Source: Picture taken and adapted from Stenmark, 2009.

### 2.5.3 Rab exclusion cascades

During the process of compartmental maturation, not only is it important to recruit a new Rab, but also to displace the previous upstream Rab. This is achieved by a process whereby the downstream Rab recruits a GAP to inactivate the upstream Rab. An example of such a cascade is seen also in yeast between Ypt1 and Ypt31. Early Golgi compartments labeled with Ypt1 eventually mature into Ypt31 positive compartments. To accomplish this, Ypt31 recruits Gyp1, the GAP for Ypt1p, to exclude Ypt1 from Ypt31 positive membranes (Rivera-Molina and Novick, 2009). Figure II.13 illustrates how such a Rab exclusion cascade would look like.

**Figure II.13. Model of Rab conversion and exclusion cascade.** In a counter Rab exclusion cascade, a downstream Rab recruits the GAP for an upstream Rab to displace it and complete the maturation. The Rab conversion cascade is also depicted, as it is thought that both cascades occur in synchrony. Source: Picture taken from Stenmark, 2009.

### 2.6 Cell-type specific functions of Rabs

Given the large number of Rabs, it was thought that they may be important for cell-type specific functions (Elferink et al., 1992). The first mammalian Rab genes were identified from rat brain and hence termed ras genes from rat brain (Rab) (Touchot et al., 1987). Since then, many more studies have elucidated the role of Rab proteins in the brain. A proteomic analysis of synaptic vesicles revealed a large number of Rabs on SVs (Takamori et al., 2006). Furthermore, Rab3 and Rab27 have been shown to be important for SV exocytosis (Mahoney et al., 2006a; Yu et al., 2008; Pavlos et al., 2010). It appears that the evolution of a nervous system has placed greater demands for regulated membrane trafficking. Since neurons are highly polarized, these cells perhaps require a large number of Rabs to regulate their

function. Interestingly, there still remain many neuronally expressed Rabs whose functions remain uncharacterized (Elferink et al., 1992; Olkkonen et al., 1994).

### **2.7 Redundancy in Rab function**

An important underlying theme in Rab function is redundancy, a strategy employed by the cell allowing multiple proteins to functionally replace each other and to efficiently modify a working mechanism. This was first observed for Rab3. There are four different genes encoding isoforms of Rab3: Rab3A, Rab3B, Rab3C and Rab3D. All four isoforms are highly expressed in the brain (Schlüter et al., 2002). Knockout studies in mice revealed that deletions in a single Rab3 gene resulted in no visible defect in SV exocytosis. Only when all four Rab3 genes are deleted, can a mild decrease in exocytosis be observed (Schlüter et al., 2004). Rab27A and Rab27B, in mice, were also shown to regulate dense granule secretion from blood platelets in a partially redundant manner (Tolmachova et al., 2007). Lastly Rab8 and Rab10 were also shown to cooperate in basolateral sorting of VSV-G (Vesicular stomatitis virus glycoprotein) in MDCK cells. Co-depletion of both Rabs leads to missorting of VSV-G to the apical membrane (Schuck et al., 2007).

### III. AIMS

Rab GTPases are the major regulators of membrane trafficking in the cell. Considering that there are over 60 members encoded in the mammalian genome, very little is known about the function of the majority of Rab GTPases. Where are they expressed? How do they all localize with respect to each other? Which effector proteins do they bind to? And how are their functions integrated?

Conducting a family-wide analysis of the Rab family in the mammalian system is a challenge. This arises, not only due to the expanded family size, but also due to the inherent redundancy present in the system. Additionally the generation of genetic tools for such a study would require significant time, before functional analyses could be performed. Therefore, we turned to the model organism *Caenorhabditis elegans*. *C. elegans* nematodes have a relatively much smaller Rab family encoding 28 Rab members (Fig. III.1) (Pereira-Leal and Seabra, 2001). Additionally, a major advantage is that deletion mutants for 90% of the Rab genes are available for analyses. Considering also that *C. elegans* retains major mammalian tissue-types, is transparent for imaging and equipped with versatile genetic tools it was decided to conduct the family-wide characterization of RAB GTPases in *C. elegans*.

The project is divided into 7 parts aimed at analyzing different properties of each *C. elegans* RAB. (I) Firstly an expression pattern analysis was conducted to understand if RABs are expressed in a cell-type specific manner. (II) Then, a detailed sub-cellular localization analysis was conducted in their respective tissues. (III) As a third step, the Rab deletion mutants were analyzed for insights into function. Since it

**Figure III.1. Comparison of the *H. sapiens* and *C. elegans* Rab families.** The human family encodes over 60 members, often with multiple isoforms for a single Rab. This is observed with Rab3, for which there exists 4 isoforms: Rab3A, Rab3B, Rab3C and Rab3D. The nematode Rab family is significantly smaller encoding only 28 members. Often there is only one isoform per Rab and never more than two. Source: Picture taken from Pereira-Leal and Seabra, 2001.

has already been shown that Rabs function redundantly together, we anticipated that this would still hold true in *C. elegans* despite the smaller Rab family. (IV) Therefore we conducted synthetic RNAi screens to elucidate, which RABs cooperate together. (V) We are also analyzing the biochemical properties of individual RABs by studying their intrinsic rates of GTP hydrolysis and affinities for GTP/GDP (conducted in collaboration with Roger Goody, Max Planck Institute for Molecular Physiology in Dortmund). (VI) As a sixth step we aimed to identify novel RAB effectors using a large scale yeast-2-hybrid approach (conducted in collaboration with Ralf Baumeister, Albert-Ludwigs-University in Freiburg). (VII) As a final step, to understand how Rabs evolved in nematodes and other species, we are conducting a detailed phylogenetic analysis of Rabs over multiple organisms (conducted in collaboration

**Figure III.2. Schematic representation of project aims.** Information about the properties of each *C. elegans* RAB was collected by an analysis of its expression pattern and sub-cellular localization. This information was then used to analyze the *rab* mutants, followed by a synthetic RNAi analysis to determine which RABs function together. In collaboration with other laboratories, we are currently also analyzing the biochemical properties of each RAB, screening through a yeast-2-hybrid approach for novel effectors and investigating how the Rab family evolved in multiple organisms.

with Dirk Fasshauer, University of Lausanne). For the thesis, only data from the parts I – IV are included, as these were the parts that represented most of the author’s PhD work. Parts V- VII were mostly initiated through collaborations and are currently ongoing. The aims of the project are summarized in Figure III.2.

Additionally it must be mentioned that experiments for parts I and II were completed solely by the author, part III was done by the author and with help from other members of the lab (Christian Olendrowitz and Marija Sumakovic) and part IV was conducted by the author with assistance from a lab technician (Sabine Koenig). Experiments where the author received help are indicated in the figure legends.

This study represents the first family-wide characterization of Rab GTPases within a model organism including an analysis of mutants. This work will serve as a reference and catalogue for scientists in the field of membrane trafficking.

## IV. RESULTS

### 4.1 Expression pattern analysis of *C. elegans* RABs

The broad-scale analysis of the *C. elegans* RAB family was initiated by analyzing the expression patterns of each individual *rab*. For this purpose, a transcriptional *promoter::gfp* fusion approach was taken. The upstream promoter region of each *rab* gene was PCR amplified and cloned by fusing it to green fluorescent protein (GFP). Promoter regions for *C. elegans* are typically defined as the genomic loci between the start codon of the gene of interest and the stop codon of the upstream gene (Boulin et al., 2006). For this study, most promoter regions cloned were approximately 3 kb in size, and also incorporated 15-20 base pairs from the start of the *rab* gene. A 3'UTR is also necessary for expression. The classical 3'UTR from the *unc-54* gene was used. All cloned promoters were injected into wild type animals to analyze GFP expression in all major *C. elegans* tissues (Fig IV.1, Fig. IV.2).

**Figure IV.1. Strategy for expression pattern analysis.** *rab* promoters were cloned and fused to GFP. The classical 3'UTR from the *unc-54* gene was used (vector: pPD115.62). *C. elegans* retains many major tissue types found in vertebrates. The expression of GFP in these tissues was analyzed for each Rab. Source: Picture adapted from Altun and Hall, 2008)

**Figure IV.2. Expression patterns of *C. elegans rabs*.** Transcriptional fusions of all *rab* promoters revealed that *C. elegans rabs* are differentially expressed in a tissue-specific manner. All animals are presented on an anterior to posterior axis. The majority of *rabs* show preference for the nervous system and the intestine in adult animals. A few predicted *rab* genes displayed no promoter activity (*rab-18.1*, *rab-y4* and *rab-y5*). Additionally, attempts to clone *rab-1* and *rab-y1* promoters were unsuccessful. Scale bar represents 200  $\mu\text{m}$ .

Primary expression pattern analysis revealed that *rabs* are differentially expressed in *C. elegans*. Some *rabs*, such as *rab-5*, *rab-6.1*, *rab-6.2*, *rab-8*, *rab-10* and *rab-11.1* were ubiquitously expressed in all tissues. Almost all *rabs* were expressed in neurons. The second major RAB containing tissue was the intestine. Additionally, some *rabs* displayed very specific expression patterns. For example, *rab-28* expression was restricted to a sub-type of neurons; the ciliated sensory neurons. The expression of *rab-30* was observed only in the glial sheath cells of the worm. *rab-21* and *rab-y6* were specifically expressed in the intestine. Interestingly *rab-18*, *rab-y4*, *rab-y5* promoters did not display any activity. Therefore, from this point onwards *rab-18.2* was denoted as *rab-18*, *rab-y4* and *rab-y5* were regarded as non-functional pseudo-genes. Attempts to amplify these from a cDNA library also

failed, further suggesting that they were not expressed. The original number of predicted *rab* genes was annotated at 31. After this expression pattern analysis, it was confirmed that there are a total of 28 *rab* genes expressed in *C. elegans*.

All the primary expression pattern data was tabulated to create a list of each *rab* matched with the respective tissues in which it is expressed (Table IV.1). It is important to note that the promoters of *rab-1* and *rab-y1* could not be amplified by PCR. Information on their expression patterns was available on [www.wormbase.org](http://www.wormbase.org) from an ongoing genome wide promoterome project and incorporated into Table IV.1.

## 4.2 Sub-cellular localization analysis of *C. elegans* RABs in neurons

Since the expression pattern analysis revealed that the majority of RABs are expressed in the nervous system, it was decided to analyze the sub-cellular localization of these RABs in neurons. For this purpose, all RABs were cloned with an N-terminal fusion to red fluorescent protein (mCherry/tagRFP) and expressed under a neuron specific promoter (*rab-3* promoter). These constructs were then co-injected with different compartmental markers (Figure IV.3). MANNOS II-YFP (Mannosidase II) was used as a marker for the Golgi. GFP-2xFYVE was used as a marker for early endosomes. CTNS-1-YFP was used as a marker for lysosomes. GFP-RAB-6.1 was used as a marker for TGN and endosomes (Eimer et al., 2007; Roggo et al., 2002).

**Figure IV.3. Strategy for sub-cellular localization analysis.** All *rab* genes were cloned and N-terminally fused with mCherry/tagRFP. The fusions were expressed in neurons under the *rab-3* promoter. Compartmental markers for Golgi, endosomes, and lysosomes were fused to GFP/YFP and co-injected to assess co-localization. Source: Picture adapted from Altun and Hall, 2008

Most neuronally expressed RABs were well localized to the Golgi (Fig. IV.4). RAB-6.1 and RAB-6.2 colocalized with the TGN and endosomes. RAB-8 and RAB-10 displayed partial overlap with Golgi and endosomal markers. RAB-14 showed a strong co-localization with RAB-6.1. RAB-35 appeared to localize specifically to neurites and neuronal processes. We are currently testing its localization relative to cytoskeletal markers. RAB-3, RAB-10, RAB-27 and RAB-37 showed strong overlap with synaptic marker proteins (data not shown). RAB-7 and RAB-28 were specific to late endosomes and lysosomes. There were a few RABs, which showed only partial

**Figure IV.4. Sub-cellular localization of *C. elegans* RABs in nervous system.** Each row represents 1-3 neuronal cell bodies, generally imaged from the VNC. Only RAB-30 was imaged in glial cells due to its restricted expression pattern. The *C. elegans* RABs localize to distinct compartments. Many show a pattern of preference for the Golgi. Images for RAB-2 were kindly provided by Marija Sumakovic. Scale bar represents 5  $\mu$ m.

colocalization to the Golgi: RAB-1, RAB-18, RAB-Y2 and GLO-1. Additionally the RAB-Y1 and RAB-37.1 showed no colocalization with the Golgi. More markers need to be tested to fine map the localizations of these RABs.

All primary data from the sub-cellular localization analysis of RABs in the *C. elegans* nervous system was tabulated and is represented in Table IV.2. Please note that additional markers were tested that are not depicted in Fig IV.4, but are described in Table IV.2.

To investigate the localizations of *C. elegans* RABs in non-neuronal tissues, we are collaborating with Barth Grant at Rutgers University, New Jersey, USA. The Grant lab is currently analyzing the localization of several RABs in the intestine.

### 4.3 Functional analysis of *rab* mutants

The expression pattern data also suggested that most *C. elegans* Rab proteins must function in modulating nervous system function. Since, nematodes display several robust nervous system mediated behaviors it was decided to systematically assay these behaviors with the *rab* mutants that were available. Figure IV.5 shows

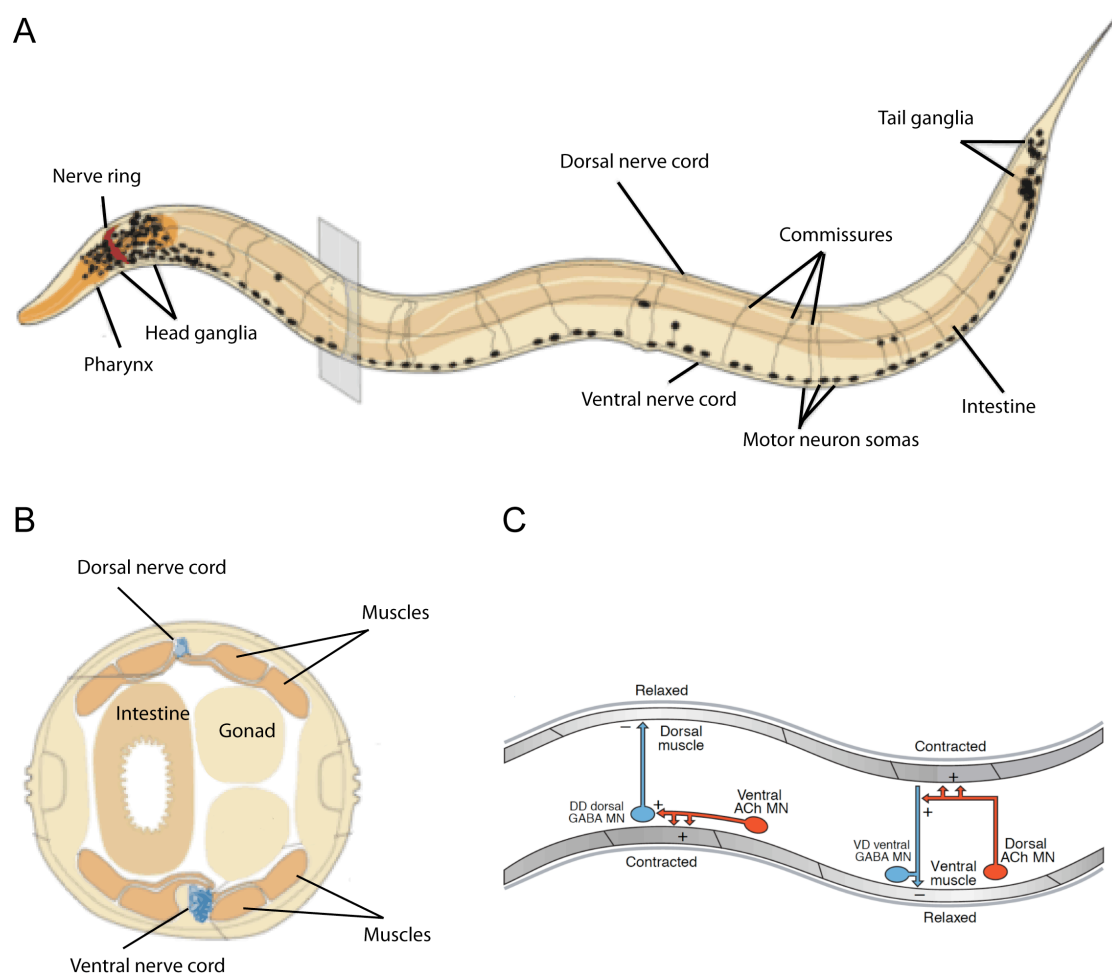

**Figure IV.5. Gene structures of all *rabs*.** The gene structures of all *rab* genes are depicted. Exons are shown as blocs and introns as connecting lines. Lethal genes are highlighted with red exons. The deletion alleles used in this study are underlined in red below the respective gene. Only mutants with nonsense mutations were available for *rab-3* and *glo-1*. No Mutants for *rab-30*, *rab-y2* and *rab-y6* were available. Although *rab-7* is lethal, it is a maternal effect lethality, which allows one generation to be assayed. Sizes of the deletions and official allele names are described in the appendix.

the gene structures of all the *C. elegans rab* genes, along with a depiction of which mutants were available for analysis and which mutants were lethal.

### 4.3.1 Movement analysis

*C. elegans* movement is a complex behavior, which is coordinated by the neuro-muscular system. The body wall muscles of *C. elegans* run in eight quadrants along the nerve cords of the animal. Four quadrants flank the dorsal nerve cord and four quadrants flank the ventral nerve cord (Fig. IV.6). There are 6 major classes of motor neurons, which are responsible for locomotion: VA, VB, VD, DA, DB and DD

**Figure IV.6. The neuro-muscular system of *C. elegans*.** **A.** *C. elegans* has a ventral and dorsal nerve cord, which run through the length of the animal's body. **B.** A cross-section of the animal reveals that the body wall muscles important for movement run as four quadrants flanking each nerve cord. **C.** All motor neurons are located in the VNC. VA, VB and VD neurons form neuro-muscular junctions (NMJs) with the ventral muscles and DA, DB and DD neurons form NMJs with the dorsal muscles. Worms move in a sinusoidal fashion. This is achieved by stimulation of muscles on one side of the animal, along with simultaneous inhibition of the muscles on the contralateral side (Schuske et al., 2004). Source: Pictures for A. and B. were provided by Stefan Eimer. Image for C was adapted from Schuske et al., 2004.

(von Stetina et al., 2006). The cell bodies of all these neurons are located in the ventral nerve cord (VNC). VA, VB, and VD form synapses with adjacent muscles in the VNC, whereas DA, DB and DD sent contralateral commissures to form synapses at the dorsal nerve cord (DNC) (Riddle et al., 1997).

The VA, VB, DA and DB motor neurons are cholinergic, whereas the VD and DD motor neurons are  $\gamma$ -Aminobutyric acid (GABA)ergic. Nematodes move in a sinusoidal fashion. This movement is mediated by the simultaneous contraction and relaxation of the ventral and dorsal muscles. The VB motor neurons activate muscles on the ventral side, and in parallel activate the DD motor neurons, which relax the muscles on the dorsal side. On the other hand, the DB motor neurons activate muscles on the dorsal side, and in parallel activate the VD motor neurons to relax the muscles on the ventral side (Figure IV.6) (von Stetina et al., 2006).

To assess if the *rab* mutants were capable of coordinated movement, we measured their movement rates. This was done by counting the number of sinusoidal body bends per minute (Figure IV.7). Wild type animals displayed a rate of  $23.47 \pm 0.72$  body bends per minute. *rab-2* mutants were severely uncoordinated and had an average rate of  $11.98 \pm 0.46$  body bends per minute. *rab-2* was previously identified in a screen for uncoordinated mutants and is hence also called *unc-108* (Brenner, 1974). All other *rab* mutants displayed normal rates of locomotion.

**Figure IV.7. Movement analysis of *rab* mutants.** The movement of all *rab* mutants was analyzed by measuring their body bends per minute. *rab-2* mutants are strongly uncoordinated. All other *rab* mutants display normal locomotion. At least N = 10 animals were tested per strain. Error bars = SEM (\*\*\*, P < 0.005; ANOVA with Bonferroni post test). Source: This experiment was conducted by the author, Marija Sumakovic and Christian Oelendrowitz.

### 4.3.2 Defecation motor program analysis

Another stereotypic behavior of *C. elegans* regulated by the nervous system is defecation. The defecation motor program of *C. elegans* occurs through a series of defined stages: The first stage involves the contraction of the posterior body muscles (pBoc), where the intestinal contents are pushed to the head. This stage is then followed by an anterior body contraction (aBoc), where the intestinal contents are sent back to the tail. The last step is the enteric muscle contraction (Emc), where the anus is opened to allow contents to be released (Fig. IV.8). This cycle occurs approximately every 45-50 seconds, when animals are kept on food. Cycle length is thought to be controlled by the intestine. Two neurons are important for Emc: DVB and AVL (Schuske et al., 2004). These neurons form atypical excitatory GABAergic synapses onto the anal depressor muscles. Ablation of AVL and/or DVB neurons abolishes the Emc and leads to accumulation of feces in the intestine (McIntire et al., 1993).

To investigate if RABs are involved in regulating the defecation motor program, we tested the *rab* mutants for defects in defecation (Fig. IV.9). Two different parameters were measured: the length of the defecation cycle (time between subsequent pBocs) and the expulsion efficiency (ratio of expulsions to pBocs). Wild type animals had a cycle length of  $46.13 \pm 0.80$  sec and a 100% expulsion efficiency. *rab-6.2*, *rab-7*, *rab-8*, *rab-18* and *rab-35* mutants displayed over 10% increases in

**Figure IV.8. The defecation motor program.** **A.** *C. elegans* defecation occurs in three steps: pBoc, aBoc and Emc. The cycle repeats itself approximately every 50 seconds when animals are on food **B.** Two neurons, AVL and DVB control the Emc by synapsing onto the anal depressor muscles. Source: Pictures taken from Schuske et al. 2004.

**Figure IV.9. Defecation analysis of *rab* mutants.** Defecation was analyzed by measuring the average cycle length (the time taken between pBocs). Additionally the expulsion efficiency for each mutant was measured. Green indicates no defect in expulsion efficiency, yellow indicates a mild defect and red indicates a severe defect. At least N = 10 animals were per strain were tested. Error bars = SEM (\*\*\*, P < 0.005; \*\*, P < 0.01; ANOVA with Bonferroni post test). Source: This experiment was conducted by the author, Marija Sumakovic and Christian Olendrowitz.

cycle length compared to wild type animals. *rab-10* and *rab-27* mutants displayed over 10% decreases in cycle length. Many *rab* mutants displayed defects in expulsion efficiency. *rab-27* mutants displayed the strongest defect in expulsion with an efficiency of  $0.02 \pm 0.01$  %. Other severely affected mutants were *rab-2* ( $63.76 \pm 0.07$  %), *rab-7* ( $58.89 \pm 0.11$  %), *rab-10* ( $54.35 \pm 0.09$  %), *rab-19* ( $55.72 \pm 0.07$  %), *rab-28* ( $51.38 \pm 0.05$  %) and *rab-35* ( $69.82 \pm 0.03$  %).

### 4.3.3 Egg-laying analysis

Another nervous system mediated behavior is egg-laying. Newly fertilized eggs remain in the uterus for 2-3 hours before being released from the vulva. The egg-laying behavior is mediated by a pair of motor neurons called the hermaphrodite specific neurons (HSNs). HSNs form serotonergic synapses with the vulval muscles. Ablation of these cells leads to defects in the frequency of egg-laying. Since these animals can still lay eggs, it is thought that they also co-release a secondary neurotransmitter (Schafer, 2005). In addition, VC motor neurons of the VNC are also important for the regulation of egg-laying (Waggoner et al., 1998).

Eggs can be categorized into three developmental stages: 0-8 cell stage, 8 cell to comma stage and postcomma stage. In wild type animals, the majority of laid eggs are in the 8-cell to comma stage. Egg-laying defective animals retain their eggs longer in the uterus and therefore lay more eggs in the postcomma stage. To investigate if

**Figure IV.10. Egg-laying analysis of *rab* mutants.** To assess egg-laying behavior, the eggs were divided into three developmental stages: 0-8 cell stage, 8 cell-comma stage and postcomma stage. In wild type animals the majority of laid eggs are in the 8 cell-comma stage. Some *rab* mutants displayed severe defects in egg-laying by laying over 30 % of their eggs in the postcomma stage. N = 20 animals per strain were tested. Source: This experiment was conducted by the author and Marija Sumakovic.

RABs are important in serotonergic neurons to modulate egg-laying, the distribution of eggs in these three stages was analyzed (Fig IV.10). *rab-2*, *rab-10* and *rab-27* animals displayed the strongest egg-laying defects. *rab-2* mutants laid 33.33 %, *rab-10* mutants laid 70.59 % and *rab-27* mutants laid 37.50 % of their eggs in the postcomma stage. *rab-8*, *rab-28*, *rab-y1* and *glo-1* displayed milder egg-laying defects by retaining 10-20% of their eggs in the postcomma stage. All other *rab* mutants appeared to display normal egg-laying behavior.

#### 4.4 Pharmacological analysis of synaptic transmission

It has been previously shown that *rab-3* mutants are important for tethering of SVs at neuronal synapses (Nonet et al., 1997). In order to identify if other neuronally expressed RABs are involved in regulating synaptic transmission, we made use of an aldicarb-based pharmacological assay.

##### 4.4.1 Aldicarb sensitivity

Aldicarb is an inhibitor of acetylcholinesterase (AChE), which breaks down acetylcholine (ACh) in the synaptic cleft. Aldicarb exposure creates a build-up of ACh leading to hyper-stimulation of postsynaptic ACh receptors at the neuro-

muscular junction (NMJ). This ultimately leads to hyper-contraction of muscles and death of animals (Fig IV.11) (Mahoney et al., 2006b).

The *rab* mutants were analyzed for their responses to aldicarb. Animals were exposed to 2 mM aldicarb and then observed after 90 minutes. The percentage of paralyzed worms in the population was measured. After exposure,  $39.81 \pm 3.34$  % of wild type animals were paralyzed. *rab-3*, *rab-14* and *rab-27* animals were significantly resistant to aldicarb with only  $13.00 \pm 3.51$  %,  $10.00 \pm 5.77$  % and  $6.53 \pm 3.85$  % animals paralyzed respectively. *rab-2*, *rab-6.2*, *rab-8*, *rab-35* and *rab-y1*

A

B

**Figure IV.11. Analysis of synaptic transmission through responses to aldicarb.** A. Aldicarb is an inhibitor of AChesterase. *C. elegans* animals, which are exposed to aldicarb, accumulate acetylcholine at the synaptic cleft of NMJs eventually leading to hyperstimulation of ACh receptors and subsequent death by hyper-contraction (Mahoney et al., 2006b). B. Percent paralysis of the *rab* mutants to 2 mM aldicarb after 90 minutes of exposure was measured. Several *rab* mutants were resistant to aldicarb, while others were hypersensitive. N = 30 animals per strain were tested. Error bars = SEM (\*\*, P < 0.01; \*, P < 0.05 Student's t test; all strains were compared with wild type). Source: This experiment was done by the author and Marija Sumakovic. Picture A. was kindly provided by Marija Sumakovic.

were hypersensitive to aldicarb with  $87.78 \pm 6.12 \%$ ,  $100.00 \pm 0.00 \%$ ,  $76.67 \pm 6.67 \%$ ,  $90.00 \pm 5.77 \%$  and  $69.64 \pm 3.71 \%$  animals paralyzed respectively (Fig. IV.11).

#### 4.4.2 Levamisole sensitivity

The results of aldicarb sensitivity assays indicated that there were several *rab* mutants with defects in synaptic transmission. In order to elucidate whether these defects were a consequence of a perturbed postsynapse, the *rab* mutants were tested for sensitivity to levamisole. Levamisole is an agonist of a subgroup of nicotinic ACh receptors (nAChRs) at NMJs. Upon exposure to levamisole, animals hyper-contract and die (Fig. IV.12) (Lewis et al., 1980). An animal's response to levamisole is largely

**Figure IV.12. Analysis of synaptic transmission through responses to levamisole.** **A.** Levamisole is an agonist of ACh receptors. *C. elegans* animals, which are exposed to levamisole, undergo hyper-activation of ACh receptors and subsequent death by hyper-contraction (Lewis et al., 1980). **B.** Percent paralysis of the *rab* mutants to 1 mM levamisole after 80 minutes of exposure was measured. Several *rab* mutants were resistant to levamisole, while others were hypersensitive. N = 30 animals per strain were tested. Error bars = SEM (\*\*\*,  $P < 0.005$ ; \*\*,  $P < 0.05$ ; \*,  $P < 0.01$ ; Student's t test; all strains were compared with wild type). Source: This experiment was done by the author and Marija Sumakovic. Picture A. was kindly provided by Marija Sumakovic.

dependent on the number, integrity and clustering of postsynaptic ACh receptors (Eimer et al., 2007; Gally et al., 2004). The effect of levamisole on the *rab* mutants was analyzed. Animals were exposed to 1 mM levamisole and then observed after 80 minutes. The percentage of paralyzed worms in the population was measured. Levamisole causes  $50 \pm 5.77$  % of wild type animals to paralyze. *rab-14*, *rab-18* and *rab-37* mutants were resistant to levamisole with only  $15.25 \pm 3.23$  %,  $29.83 \pm 5.23$  % and  $29.73 \pm 1.84$  % of animals paralyzed respectively. *rab-2*, *rab-6.2* and *rab-10* were hypersensitive to levamisole with  $100.00 \pm 0.00$ ,  $100.00 \pm 0.00$  and  $89.68 \pm 5.20$  % animals paralyzed respectively (Fig. IV.12).

#### 4.5 Analysis of ciliated sensory neurons in *rab* mutants

Among the 302 neurons present in *C. elegans*, a significant number (60) are ciliated sensory neurons dedicated to sensing the external environment (Heiman and Shaham, 2007). Since the RABs are expressed in the nervous system and are important regulators of membrane trafficking, we reasoned that they may regulate either the formation of these ciliated sensory neurons or the function of these neurons.

##### 4.5.1 DiI staining of amphids and phasmids

To assess the integrity of the chemosensory neurons, we took advantage of DiI. DiI is a lipophilic dye that fills specifically the amphid sensory neurons in the head and also the phasmid sensory neurons in the tail. The mechanism of dye uptake is not clearly understood, but it is thought to enter via the endings of the ciliated sensory neurons, which are open to the environment. Figure IV.13 shows the anatomical location of the amphids and phasmids (Tong and Bürglin, 2010).

All the *rab* mutants were stained with DiI and their amphids and phasmids neurons were imaged (Fig. IV.14). *dyf-11* was used as a control because these

**Figure IV.13. Anatomic depiction of *C. elegans* chemosensory neurons.** The amphid neurons are located in the head and the phasmid neurons are located in the tail of the worm. Both sets of neurons are readily stained by DiI, which migrates up the sensory openings. Source: Picture taken and adapted from Bargmann, 2006.

**Figure IV.14. DiI staining of *rab* mutants.** **A.** DiI staining of the amphid sensory neurons revealed that the morphology of these neurons and their ability to uptake external dyes was intact in all *rab* mutants. Bar represents 60  $\mu\text{m}$ . **B.** DiI staining of the phasmid sensory neurons revealed that the morphology of these tail neurons was largely unaffected in *rab* mutants. Interestingly, only *rab-2* mutants appeared to have a strong defect in phasmid dye uptake. Bar represents 60  $\mu\text{m}$ .

mutants have a severe failure to uptake DiI (Bacaj et al., 2007). Interestingly, the *rab-2* mutants had a defect in the uptake of DiI in the phasmid sensory neurons. Aside from *rab-2* all other *rab* mutants did not display any obvious abnormalities in dye filling.

#### 4.5.2 Analysis of amphid neuron function

Despite normal morphology, it is still possible that these neurons are impaired in their function. Therefore, we tested the responses of the amphid neurons to chemical substances. *C. elegans* displays attraction and avoidance responses to a variety of substances. Among these, copper creates a robust avoidance response through the ASH sensory neuron and isoamyl alcohol creates a robust attraction response through the AWC sensory neuron (Bargmann, 2006). A qualitative assay was set up to test these two responses. Unseeded plates with a line of 150 mM CuSO<sub>4</sub> drawn through the middle were prepared. Strains of interest were then spotted to one half of the plate and a drop of isoamylalcohol (1:10) was spotted onto the other half of the plate (Fig. IV.15) (Wicks, 2000).

**Figure IV.15. Responses of *rab* mutants to copper and isoamyl alcohol.** A. An attraction/avoidance assay was set up to chemosensory responses of the *rab* mutants. Plates lined with 150 mM CuSO<sub>4</sub> were prepared. Animals were placed on one half of the plate and a drop of isoamyl alcohol (1:10) was placed on the opposite side. After 45 minutes, the animals that crossed the copper line were qualitatively assessed. B. All *Rab* mutants were tested with this assay. They displayed mostly normal sensory responses to copper and isoamyl alcohol. *rab-10* mutants displayed a mild defect in avoiding copper. ++ Indicates at least 40% of the population crossed the copper line and + indicates between 10-20 % of population crossed the copper line. Source: Picture was originally prepared by Alejandro Mendoza (lab rotation student).

The number of animals, which crossed the line of copper, was then assessed qualitatively. All *rab* mutants were normally attracted to isoamyl alcohol and avoided copper. *rab-10* mutants displayed a mild defect in sensing copper.

#### 4.6 Synthetic RNAi analysis of *rab* mutants

Strikingly, most functional assays revealed that *rab* mutants are healthy and have fairly mild phenotypes. We reasoned that this is most likely due to redundancy in RAB function. To understand, which RABs overlap in their function a synthetic RNAi screen was conducted. For this purpose, all *rab* mutants were crossed into an RNAi hypersensitive strain (either *eri-1* or *rrf-3*: to increase RNAi efficiency) and then co-depleted by RNAi with the remaining 27 Rabs. Initially the *rrf-3* strain was used. However, due to the sickness in this background, the healthier *eri-1* strain was used. Furthermore, RNAi potency appeared stronger with *eri-1* as judged by the recapitulation of known phenotypes. Synthetic phenotypes were then scored independently by two observers. All synthetic interactions are displayed in Fig IV.16. A large variety of interactions were observed including synthetic lethality, uncoordinated behavior, egg-laying defects, sterility etc. For example *rab-8* and *rab-10* displayed reciprocal synthetic lethality. *rab-6.1* and *rab-6.2* were also observed to be synthetically lethal. *rab-3* and *rab-21* were also synthetically lethal, as were *rab-19* and *rab-21*. Furthermore, *rab-35* was uncoordinated when co-depleted with *rab-7*. This was further verified by analysis of the double mutants (data not shown). The *rab-3; rab-27* double mutant displayed synthetic uncoordinated behavior with *rab-37*. Interestingly, among all the mutants that were screened, *rab-2* mutants showed the largest number of genetic interactions with other *rabs*.

**Figure IV.16. Synthetic RNAi screen with *rab* mutants.** Each *rab* mutant was crossed into either the *eri-1* or *rrf-3* RNAi hypersensitive background. Initially the *rrf-3* background was used, but because these animals were relatively unhealthy, we chose to use the healthier *eri-1* background. Furthermore the potency of RNAi, as judged by specific phenotypes, was stronger in the *eri-1* background. The majority of *rab* mutants are in the *eri-1* background, unless otherwise indicated. Each *rab* mutant was co-depleted with the remaining 28 *rabs* via feeding RNAi. Additionally a *rab-3; rab-27* double mutant was also screened. Two independent observers scored phenotypes. All phenotypes are described by their three letter acronyms, which are explained in the legend.

## V. DISCUSSION

### 5.1 The *C. elegans* genome encodes 28 differentially expressed *rabs*

Rabs are the largest family of small GTPases. With over 60 members encoded in the human genome, they are involved in multiple steps of membrane trafficking. Despite, the large family size, relatively little is known about these proteins. In order to gain insights on *rab* function we exploited the model organism *C. elegans*. Being a genetically tractable organism, with a short generation time, it provided several advantages in contrast to other model organisms. Furthermore, mutants for 90% of the *rabs* were available for analysis.

In *C. elegans*, originally it was predicted that there are 31 *rab* open reading frames expressed ([www.wormbase.org](http://www.wormbase.org)). This study was initiated through a systematic analysis of the expression patterns of each of these 31 genes. By analyzing the promoter activity of these genes, it was determined that there are only 28 actively expressed *rab* genes in *C. elegans*. *rab-18.1*, *rab-y4* and *rab-y5* did not reveal any expression and appear to be pseudogenes. The expression of these genes in other developmental stages also revealed no expression, nor could these genes be amplified out of a cDNA library. Interestingly, *rab-y4* and *rab-y5* have high similarity to *rab-2* suggesting that they are possibly recent duplications, which have not become active. Alternatively, it is also possible that these genes are expressed in very low levels, or that longer promoter constructs incorporating additional regulatory elements are necessary to observe expression. An RT-PCR experiment to measure mRNA levels of *rab-y4* and *rab-y5* would help to detect low-level expression.

An important finding from the expression pattern analysis was that although some *rabs* were ubiquitously expressed, the majority was expressed in a tissue specific manner. When comparing with the mutants available, it was observed that

most of the ubiquitously expressed *rabs* (*rab-1*, *rab-5*, *rab-6.1*, *rab-7* and *rab-11.1*) were lethal when depleted suggesting that these have a more general role in membrane trafficking. Furthermore, the orthologues of these *rabs* have been shown in the mammalian system to be essential regulators of trafficking (Nuoffer et al., 1994; Stenmark et al., 1994; Martinez et al., 1994; Feng et al., 1995; Ullrich et al., 1996). The nervous system expressed the highest number of RABs in *C. elegans*. Due to the highly polarized nature of neurons, it is likely that they have a greater demand for regulated membrane trafficking than other cell-types. In line with our results, an alternative approach to study neuronally expressed genes in *C. elegans* via microarray profiling also identified many RABs (von Stetina et al., 2007). Furthermore studies in *H.sapiens* and *D. melanogaster*, have also showed that many Rabs are tissue-specific and enriched in the nervous system (Takamori et al., 2006; Pavlos et al., 2010; Elferink et al., 1992; Olkkonen et al., 1994; Zhang et al., 2007).

Among the neuronally expressed *rabs*, *rab-3*, *rab-27* and *rab-37* were the most specific. Interestingly, when looking at the *C. elegans rab* phylogenetic tree, these RABs fall into the functional group III by virtue of their similar structures (Pereira-Leal and Seabra, 2001). This suggests that these three Rabs coordinate together in regulating neuronal membrane trafficking. Interestingly, it has already been shown that two of these Rabs: RAB-3 and RAB-27 function together in SV exocytosis in *C. elegans* (Mahoney et al., 2006a).

The expression patterns of *rab-28* and *rab-30* were particularly interesting because they were restricted to just a few cells. *rab-28* was identified to be expressed only in a subset of neurons, the ciliated sensory neurons (amphids and phasmids). *rab-30* was found to be expressed only in the glial sheath cells which ensheath the amphid and phasmid neurons. These expression patterns suggest that these RABs play a role in the formation of sensory organs or in the trafficking of specific cargos in these cells. Interestingly, *rab-28* mutants did not display any obvious defects in sensory neuron function. However, preliminary data suggests that, when RAB-28 is co-depleted with RAB-Y3 or RAB-Y6, a defect in avoiding copper was identified (data not shown). Copper avoidance is mediated by the alpha subunit of a G-protein coupled receptor (GPCR), GPA-3, which is specifically expressed by the ASH chemosensory neuron (Bargmann, 2006). It is possible that RAB-28, RAB-Y3 and RAB-Y6 may be involved in the transport of the GPCR involved in copper sensation. Unfortunately, a *rab-30* mutant was not available for analysis.

## 5.2 Multiple RABs localize to the Golgi in neurons

An important task to understanding RAB function is to identify which compartments they localize to. Since many of the *C. elegans* RABs were expressed in neurons, we decided to systematically analyze their sub-cellular localizations in these cells. Results revealed that RABs localize to distinct compartments in neurons. For example RAB-1 and RAB-2 localized to the Golgi, RAB-6.1, RAB-6.2 and RAB-14 localized to the TGN-endosomal interface, RAB-5 localized to endosomes/synapses, RAB-3, RAB-27, RAB-37 localized to the Golgi/synapses and RAB-28 localized to lysosomes. Despite the varied localization patterns, surprisingly a lot of RABs also showed partial or full co-localization with the Golgi. Since the Golgi is a major hub of intracellular trafficking, where most cargos travel through, it would make sense that many RABs are required to ensure efficient sorting. The precise localization of some of the RABs (RAB-1, RAB-8, RAB-10, RAB-18, RAB-Y1, RAB-Y2 and GLO-1) could not be identified, as they showed only partial or no overlap with the markers tested. A tempting idea would be that some of these label novel compartments.

When compared with their mammalian orthologues, *C. elegans* RABs display conserved localization patterns. In agreement with our study, a recent analysis of the localization of Rabs in primary hippocampal neurons showed that many Rabs are localized to the perinuclear region most likely at the Golgi or endosomes (Pavlos et al., 2010). Additionally, Rab3 and Rab27 have been found to localize to synapses, Rab5 has been reported to localize to endosomes, Rab6 and Rab14 were shown to localize to the TGN-endosomal system (Griffiths et al., 1994; Pavlos et al., 2010; Stenmark et al., 1994; Mallard et al., 2002; Junutula et al., 2004).

Second to the nervous system, the *C. elegans* intestine expressed the largest number of Rabs. We are currently analyzing the localization of these intestinally expressed Rabs with the help of Barth Grant at Rutgers University, New Jersey, USA.

## 5.3 RAB function in the *C. elegans* nervous system

### 5.3.1 Role of RABs in regulating simple behaviors

After having established that RABs are predominantly found in neurons, we attempted to analyze their functions in these cells. This was carried out first by assaying several nervous system controlled behaviors: movement, defecation and egg-

laying. Movement is controlled by a set of cholinergic and GABAergic motor neurons that function in parallel together (Fig. IV.6). Analysis of *rab* mutants showed that only *rab-2* mutants were defective in movement. It has recently been shown that the movement defect of *rab-2* mutant animals arises from a defect in dense core vesicle signaling (Sumakovic et al., 2009; Edwards et al., 2009).

Analysis of defecation revealed that a number of *rab* mutants had a severe decrease in expulsion efficiency. Among these were *rab-2*, *rab-7*, *rab-10*, *rab-19*, *rab-27*, *rab-28* and *rab-35* mutants. *rab-27* also called *aex-6* (aboc expulsion defective) has been previously identified in a screen for Aex mutants, but the precise role of RABs in regulating expulsion is unclear (Thomas, 1990). Expulsion is controlled by two motor neurons DVB and AVL (Fig. IV.8). It has been suggested that RAB-27 functions in the intestine to regulate the secretion of neuropeptides, which consequently activate the excitatory GABAergic DVB and AVL motor neurons (Mahoney et al., 2008). It is possible that additional RABs could participate together with RAB-27 to fine-tune this process. Since *rab-27* is also expressed in the nervous system and since it has been shown to be involved in synaptic vesicle exocytosis, it is possible that RAB-27 regulates the secretion of GABA directly from the DVB and AVL neurons. In such a scenario, the expulsion defective RABs, which were identified in this study, may also work alongside RAB-27 in SV exocytosis.

The length of the defecation cycle was also measured for each *rab* mutant and several mutants displayed increased cycle length while others had shorter cycle lengths. It has been demonstrated that cycle length is controlled by a calcium dependent mechanism. In synchrony with the pBoc, albeit occurring slightly earlier in time are a series of calcium transients in the intestine (Branicky and Hekimi, 2006). Mutations in an ER localized Inositol(1,4,5)trisphosphate (IP<sub>3</sub>) receptor (ITR-1), displayed a loss of intestinal calcium transients and a consequent increased cycle length. Overexpression of ITR-1 led to shorter cycles (Dal Santo et al., 1999). Additional genes involved in the generation of IP<sub>3</sub> such as phospholipase C (PLC) have also been implicated in regulating cycle length (Espelt et al., 2005). Rab GTPases have been shown to directly interact with phosphoinositide kinases and phosphatases (Shin et al., 2005; Stenmark, 2009). As a result of these interactions, they modulate the phosphoinositol pools in the cell. It is possible that *rab* mutants may change the levels of Phosphoinositol (4,5) bisphosphate (PIP<sub>2</sub>). Since PIP<sub>2</sub> is a precursor for the formation of IP<sub>3</sub>, changes in PIP<sub>2</sub> levels may affect the length of the

defecation cycle. Interestingly *rab-3*, *rab-6*, *rab-8*, and *rab-35* mutants displayed an increase in cycle length. The mammalian orthologues of these Rabs were shown to bind the inositol-polyphosphate 5-phosphatase, OCRL (Oculocerebrorenal syndrome of Lowe) (Fukuda et al., 2008).

Movement and defecation are primarily controlled by cholinergic and GABAergic neurons. To verify if RABs were also important in regulating monoamine transmitter release, we tested the *rab* mutants for defects in egg-laying. Egg-laying is mediated by the hermaphrodite specific neurons (HSNs) as well as VC neurons, both of which secrete serotonin (Schafer, 2005). The egg-laying assay revealed that *rab-10* mutants displayed the strongest egg-laying defect. It is possible that RAB-10 may either regulate the development of the HSN and VC cells or be directly involved in the secretion of serotonin containing vesicles.

### 5.3.2 Role of RABs in regulating synaptic transmission

RAB-3 and RAB-27 have been shown to function together in regulating SV exocytosis at the *C. elegans* NMJ (Mahoney et al., 2006a). To investigate if additional RABs were involved in SV exocytosis, we used a pharmacological aldicarb based assay that allows an assessment of secreted ACh levels. Generally, aldicarb hypersensitivity suggests increased secretion, whereas aldicarb resistance suggests decreased secretion. However, sensitivities to aldicarb may also change as a consequence of an altered postsynapse. To distinguish between the two possibilities, aldicarb response assays are done in parallel to levamisole response assays. *rab-3* and *rab-27* mutants were, as previously shown, less sensitive to aldicarb, but responded normally to levamisole. This suggests a decrease in SV release and correspondingly less ACh release. Previous aldicarb assays on *rab-3* and *rab-27* mutants support this (Mahoney et al., 2006b). In addition to these two *rabs*, *rab-14* mutants were also aldicarb resistant. Interestingly *rab-14* mutants also showed a resistance to levamisole suggesting fewer nAChRs at the postsynaptic muscle cell surface. It is possible that RAB-14 functions in the transport of nAChRs or perhaps in the degradation/recycling of these receptors. In accordance with this, it was recently shown that the mammalian orthologue of RAB-14 is indirectly involved in fibroblast growth factor receptor (FGFR) trafficking to the plasma membrane (Ueno et al., 2011).

Other *rab* mutants displayed hypersensitivity to aldicarb: *rab-2*, *rab-6.2*, *rab-8*, *rab-35* and *rab-y1*. Interesting, *rab-2* mutants were also hypersensitive to

levamisole suggesting that in these mutants there is an increase in nAChRs at the postsynaptic side. This could occur due to a failure in efficient receptor degradation or recycling. It has been shown that at glutamatergic synapses, AMPA receptors are endocytosed and sorted into late endosomes for degradation or into recycling endosomes for replacement at the cell surface (Ehlers, 2000). It is possible that a similar mechanism exists at cholinergic synapses for nAChRs. RAB-2 has already been suggested to be involved in the recycling of AMPA receptors at glutamatergic synapses in *C. elegans* (Chun et al., 2008). The hypersensitive response of *rab-6.2* mutants to aldicarb and levamisole is not likely to be due to changes in synaptic transmission. Observation of these mutants showed that they are very sick and burst upon reaching adulthood. Further experiments demonstrated that these mutants have blisters on their cuticula (data not shown). It is possible that a weaker cuticle would allow drugs to penetrate more easily, causing the animals to be hypersensitive.

The phenotype of *rab-10* mutants was especially interesting because they displayed no change in aldicarb sensitivity, but were hypersensitive to levamisole. The hypersensitivity to levamisole is indicative of a postsynaptic defect. One possible explanation could be that the channel properties of the nAChRs are affected in *rab-10* mutants rendering them more sensitive to levamisole. This could potentially occur due to erroneous post-translational modifications as the receptors are transported to the cell surface or due to perturbed receptor recycling. In agreement with this, a previous study has implicated RAB-10 in AMPA receptor recycling in *C. elegans* neurons (Glodowski et al., 2007). It could also be that *rab-10* mutants have both, a presynaptic defect and a postsynaptic defect. In such a case, *rab-10* mutants could be secreting less ACh, but the results of the aldicarb assay would be masked by a hypersensitive postsynapse. Repeating these experiments with *rab-10* mutants rescued with *rab-10* expression only in the muscles would help to differentiate these possibilities. *rab-8*, *rab-35* and *rab-y1* mutants showed hypersensitivity to aldicarb and normal sensitivity to levamisole. These results are indicative of increased levels of steady state SV exocytosis. It could be that the basal secretion levels are increased in these mutants.

### 5.3.3 Role of RABs in regulating chemosensation

Since a large portion of the *C. elegans* nervous system is dedicated to sensing the environment, we verified if *rab* mutants had obvious defects in the chemosensory

system. DiI staining of the amphids and phasmids showed that all mutants were similar to wild type except *rab-2* mutants. *rab-2* mutants displayed normal dye filling in the amphids, but failed to efficiently fill in the phasmids. Interestingly, mutants with similar defects have been identified in dye filling screens (Herman and Horvitz, 1994). Interestingly, one such mutant, *eor-1*, has also been shown to have defects in movement, similar to *rab-2* mutants. EOR-1 is a transcription factor important for cell differentiation (Hoepfner et al., 2004). Rab GTPases involved in membrane trafficking have previously been shown to bind effectors, which translocate to the nucleus to alter gene expression (Miaczynska et al., 2004). Additional experiments are necessary to understand if there is a link with RAB-2 and the regulation of gene expression.

It would also be interesting to test the functionality of the phasmid neurons in *rab-2* mutants. It has been shown that these neurons, PHA and PHB, are negative modulators of sensory avoidance behaviors (Hilliard et al., 2002). Since we only tested for copper avoidance, which is mediated by ASH neurons, it would explain why no phenotype was observed in this assay. Interestingly, *rab-10* mutants displayed a mild defect in copper avoidance. This may be due to a missorting of the GPCR necessary for copper sensation in these mutants (Bargmann, 2006).

#### **5.4 C. *elegans* RABs function redundantly together**

Knockout and knockdown analysis of mammalian Rabs showed a high degree of functional redundancy. Rab3A, Rab3B, Rab3C and Rab3D work together in SV exocytosis (Schlüter et al., 2004). Furthermore, Rab27A and Rab27B were shown to work together in dense granule secretion from platelets (Tolmachova et al., 2007). Based on these data, we thought initially that the *C. elegans* RABs may be less redundant due to its smaller family size. However, from the results of this study, it was striking to see that despite the smaller *C. elegans* RAB family, many of the *rab* mutants were healthy and few displayed strong defects. To understand which RABs were working together, a synthetic RNAi screen was conducted with the *rab* mutants. Each *rab* mutant was co-depleted with the remaining 27 *rabs*. Overall, the screen revealed that simultaneous removal of more than one RAB leads to more obvious phenotypic alterations. The strongest genetic interactions observed were synthetic lethals. It was found that *rab-8* and *rab-10* mutants are synthetically lethal in a reciprocal manner. Additionally it was observed that *rab-3* and *rab-19* mutants were

synthetically lethal with *rab-21 RNAi*. However, these interactions were not reciprocal. One possible explanation for this is that the RNAi of *rab-3* and *rab-19* was not efficient enough to cause a synthetic lethality. Therefore, in this case it would be a good idea to try other RNAi methods; RNAi by injection or soaking have been shown for certain genes to cause a better knockdown (Kamath et al., 2001; Tabara et al., 1998).

Other nervous system mediated phenotypes were also observed such as Unc and Egl. Unc was observed when *rab-35* mutants were knocked down with *rab-7*. A double mutant of these two *rabs* recapitulated the RNAi phenotype (data not shown). Interestingly, *rab-27* mutants were Unc when co-depleted with *rab-3*, in accordance with a previous analysis of these mutants (Mahoney et al., 2006a). Among all the *rab* mutants, *rab-2* animals displayed the largest number of genetic interactions with other *rabs*. Considering that RAB-2 is also the most highly conserved RAB GTPase across all species, it is likely that it is a central regulator of Golgi trafficking.

Out of interest, we also screened the *rab-3; rab-27* double mutant to look for additional genetic interactions. We found that *rab-3; rab-27* double mutants, which were co-depleted with *rab-37*, were more severely Unc. This suggests that RAB-37 may have a previously unidentified role in regulating SV release. Interestingly, *rab-37* displayed very specific expression in neurons similar to *rab-3* and *rab-27*. Additionally all three of these genes are classified in one functional group by virtue of structural similarities (Pereira-Leal and Seabra., 2001).

Through these screens we have identified novel combinations of RABs that may function together. In a next step it is necessary to validate and characterize these interactions using the mutants available to gain a more mechanistic understanding of how different RABs work together. It is also conceivable that double mutants can additionally be screened to identify triply redundant RABs.

## **CHAPTER 2:**

### **REGULATION OF DENSE CORE VESICLE SECRETION BY RAB GTPASES IN *C. ELEGANS***

## VI. INTRODUCTION

As the second chapter of the thesis will deal with the role of RAB GTPases in regulating dense core vesicle (DCV) secretion *C. elegans*, a brief introduction into the protein machinery behind SV and DCV exocytosis is provided.

### 6.1 The SV exocytosis machinery

Neurotransmitter release through SV exocytosis is the principle mode of intercellular communication in the brain. During this process, SVs filled with neurotransmitters move towards the presynaptic active zone, where they dock with the plasma membrane. After docking, SVs prepare for release through a process called priming, which renders them more competent to fuse. Upon an influx of calcium, vesicles fuse with the plasma membrane. After a fusion event, SVs are recycled most likely by endocytosis (Fig. VI.1) (Richmond, 2005). A number of critical proteins, in addition to Rabs, have been identified to make up the SV release machinery: Synaptobrevin-2, syntaxin-1, SNAP-25, Munc18, synaptotagmin-1, Munc13, complexin, tomosyn, and CAPS (Ca<sup>2+</sup>-dependent activator protein for secretion) (Richmond, 2005; Soerensen, 2009). These components are shown in figure VI.1.

SNAREs were the first basic components identified shown to be necessary for fusion (Weber et al., 1998). Synaptobrevin-2 is an R-SNARE localized on the membrane of synaptic vesicles. Syntaxin-1 (Qa SNARE) and SNAP-25b (Qbc SNARE) are localized at the plasma membrane of presynaptic terminals (Sutton et al., 1998; Fasshauer et al., 1998). These three SNAREs are capable of assembling rapidly into a *trans*-SNARE complex via an N to C terminal zipper mechanism (Pobbati et al., 2006). The assembly of R and Q SNAREs into a four helical bundle

**Figure VI.1. The synaptic vesicle cycle and its machinery.** **A.** Synaptic vesicles are loaded with neurotransmitter at the synapses and subsequently undergo fusion at the presynaptic terminal. Fusion has been described to occur through docking, priming, calcium sensing and subsequent fusion. The discreteness of these steps is becoming more clear as better understandings of the protein machinery are emerging (Richmond, 2005). **B.** A number of proteins are implicated in SV docking, priming and fusion: SNAREs, Munc18-1, Synaptotagmin-1, Munc-13-1 and complexin. CAPS and tomosyn have also been shown to be involved, but are not depicted above (Rizo and Rosenmund, 2008). Source: Pictures taken from Richmond, 2005; Rizo and Rosenmund, 2008.

is thought to provide the energy necessary for membrane fusion (Jahn and Scheller, 2006).

Munc18 is a 60 kDa cytosolic protein, which has been shown to bind to the closed conformation of Syntaxin-1 (Habc domain closed onto the SNARE domain) (Dulubova et al., 1999). However, more recently it has been shown that Munc18 can also bind to the assembled SNARE complex through a previously unidentified N-terminal peptide of Syntaxin-1a (Shen et al., 2007; Burkhardt et al., 2008). The mechanism of action on SNARE assembly is a subject of controversy as results from *in vitro* studies yield conflicting data. Shen et al. suggested that N-peptide binding accelerates SNARE complex assembly, whereas Burkhardt et al. suggest that abolishing the N-peptide interaction allows SNARE complex formation (Shen et al., 2007; Burkhardt et al., 2008). *In vivo* studies have showed that deletion of Munc18 in mice leads to a sharp decline in SV release suggesting that Munc18 has a stimulatory function for SNARE driven exocytosis (Verhage et al., 2000). The precise sequence of events in which Munc18 interacts with Syntaxin-1 and the SNARE complex remains to be elucidated.

Early studies by Katz showed that the release of SVs is triggered by the influx of  $\text{Ca}^{2+}$  (Katz, 1969). This process intuitively demanded the requirement of a calcium sensor. Since then, it has been determined that C2 domain containing proteins called

synaptotagmins (65 kDa) could take up this role. C2 domains possess dual functions:  $\text{Ca}^{2+}$  binding ( $\sim \text{Kd } 50 \mu\text{M}$ ) as well as phospholipid binding (Nalefski et al., 2001). Considering also that synaptotagmin-1 (syt-1) localized to SVs, syt-1 was proposed to be the major calcium sensor. In accordance with this, mice knockouts of syt-1 revealed that it is essential for synchronous evoked SV release (Geppert et al., 1994; Chapman, 2008). Interestingly there are 16 mammalian synaptotagmins, the majority of which remain functionally uncharacterized (Pang and Südhof, 2010).

Munc13s are large ( $\sim 200$  kDa) multi domain containing proteins. Munc13-1 is involved in SV priming (Augustin et al., 1999). It contains a C1 domain, three C2 domains (C2A, C2B and C2C), a calmodulin (CaM) binding domain and a MUN domain (Fig. VI.2) (Brose et al., 1995; Shin et al., 2010). The C1 domain was shown to act as a receptor for binding phorbol esters such as diacylglycerol (DAG) (Ahmed et al., 1992; Betz et al., 1998). The three C2 domains are thought to differ in their functions (Brose et al., 1995). Recently it was shown that only the C2B is important for binding calcium ( $< \text{Kd } 100 \mu\text{M}$ ) and phosphoinositolphosphate lipids (Shin et al., 2010). The CaM domain was also shown recently to bind to  $\text{Ca}^{2+}$ -CaM, which is thought to further facilitate SV priming (Rodriguez-Castaneda et al., 2010). Finally, the MUN domain is thought to directly or indirectly bind and open syntaxin-1 (Habc domain from SNARE domain) to allow for SNARE complex assembly (Madison et al., 2005; Richmond et al., 2001; Basu et al., 2005). However, the biochemical mechanism of how the MUN domain of Munc13 regulates SNARE assembly and also how it works in concert with Munc18 remains unclear. Interestingly the N-terminus of Munc-13 has also been shown to bind the Rab3 effector, RIM1 (Betz et al., 2001; Wang et al., 1997). *In vivo* deletions of Munc-13 or RIM1 lead to similar decreases in SV release (Varoqueaux et al., 2002; Schoch et al., 2006). Furthermore,

**Figure VI.2. Domain structure of Munc13-1.** Munc13-1 is a multidomain protein. It consists of a C1 domain important for DAG binding, three C2 domains of which C2B is important for calcium binding, a CaM domain important for binding calmodulin and a MUN domain which is suggested to regulate SNARE assembly. Source: Picture taken and adapted from Shin et al., 2010.

RIM1, like Munc13, is also thought to be necessary for opening syntaxin-1 (Koushika et al., 2001).

Complexins are small 15 kDa cytosolic proteins (complexin 1 and 2) that were identified to bind with high affinity to the assembled SNARE complex in a 1:1 ratio (McMahon et al., 1995; Chen et al., 2002). The role of complexins on SV release has been studied in a wide variety of model systems, yielding conflicting data. However, in general it has been described that changes in cellular levels of complexin (overexpression or depletion) leads to a decrease in spontaneous and evoked exocytosis (Brose, 2008). Furthermore, from mouse knockout studies it is clear that the function of complexin is carried out through its binding to the assembled SNARE complex (Reim et al., 2001; Xue et al., 2007). Studies with complexin mutants in *D. melanogaster* and *C. elegans* have revealed similar results for complexins' role in evoked release, but a contradictory increase in spontaneous release (Huntwork and Littleton, 2007; Hobson et al., 2011). Interestingly knockdown, as opposed to knockout, of complexin in mice reveals similar phenotypes as in flies and worms (Yang et al., 2010). This suggests that complexin may have an additional clamp function to minimize calcium-independent secretion events. With respect to the other components of SV fusion, it is thought that complexin binds to the SNARE complex keeping it in a primed state and that calcium entry triggers complexin displacement by synaptotagmin (Brose, 2008).

Tomosyn is a 130 kDa cytosolic protein that is found to be an inhibitor of SV release. It consists of two major domains: an N-terminal domain with WD40 repeats as well as a C-terminal R-SNARE domain. The inhibitory action of tomosyn was identified to be a result of competition with the neuronal R-SNARE, synaptobrevin-2, for SNARE assembly leading to less fusion (Hatsuzawa, 2003). The Tomosyn-SNARE complex and the Synaptobrevin-SNARE complex represent end products of the assembly reaction. The N-ethylmaleimide-sensitive factor (NSF) is necessary for disassembly (Pobbati et al., 2004). In accordance with this role of tomosyn, *in vivo* studies have also shown that deletion of tomosyn leads to more sustained SV release (Hatsuzawa, 2003; Gracheva et al., 2007).

CAPS is a 145 kDa cytosolic protein originally identified to be a component of the DCV secretion machinery (Walent et al., 1992). Since then it has also been shown to be control SV release (Jockusch et al., 2007). CAPS is a multidomain

**Figure VI.3. Domain structure of CAPS-1.** CAPS is also a multidomain protein. At the N-terminus it has a dynactin binding domain (DBD). This is followed by a C2 domain, a PH domain a MUN domain and a C-terminal DCV binding domain. Source: picture taken from Stevens and Rettig, 2009.

protein containing an N-terminal dynactin binding domain (DBD), followed by a C2 domain, a Pleckstrin homology (PH) domain, a MUN domain and a C-terminal DCV binding domain (Fig. VI.3). Not much is known about the DBD except that it is likely to have a sorting function. The C2 domain is suggested to be important for  $\text{Ca}^{2+}$  mediated membrane binding, although it was showed to have only moderate affinity for  $\text{Ca}^{2+}$  ( $\sim K_d$  270  $\mu\text{M}$ ) (Ann et al., 1997). The PH domain was identified to be important for membrane binding, perhaps through cooperating with the C2 domain (Grishanin et al., 2002). The MUN domain of CAPS is similar to the MUN domain of Munc13 and is thought to be perhaps important for SV priming via interaction with SNAREs (Stevens and Rettig, 2009). The C-terminal DCV domain has been shown to be necessary for localization onto DCVs (Grishanin et al., 2002). *In vivo* analysis of CAPS knockout mice (double CAPS1 and CAPS2 knockout), have revealed that CAPS1 is essential for evoked SV release and is partially redundant with CAPS2 (Jockush et al., 2007). It has been suggested that it may also participate in opening syntaxin-1, together with Munc13, although electrophysiological evidence for this is not yet available for neurons (Hammarlund et al., 2008).

The exact sequence in which all of the SV exocytosis machinery work together remains still a mystery. Current working models with some of these factors suggest that as SVs approach the active zone, docking is likely mediated by a Rab GTPase (Rab3 / Rab27) in an interaction with a Rab effector (RIM-Munc13) in complex with SNAP-25, syntaxin-1, Munc18 (the acceptor complex). After docking synaptobrevin on SVs binds to the acceptor complex with its N-terminus to form an intermediate SNARE complex, where the C-terminus of synaptobrevin would be kept unstructured. At this point, it is also thought that synaptotagmin and complexin bind to this intermediate SNARE complex stabilizing it to facilitate priming. Upon an influx of calcium, complexin is displaced and synaptotagmin is thought to provide the force for the final fusion and full SNARE assembly (Sorensen, 2009; Brose, 2008).

## 6.2 The DCV exocytosis machinery

In contrast to SVs, dense core vesicles are loaded with bioactive peptides and function to modulate fast synaptic transmission. Most of our current understanding of the DCV secretion machinery comes from experiments conducted on neuroendocrine chromaffin cells of the peripheral nervous system. These cells contain mostly large DCVs (~200 nm) that fuse in a calcium dependent manner. These events are detectable through capacitance measurements and amperometry (Neher and Marty, 1982; Chow et al., 1994; Voets, 2000). Genetic analysis in chromaffin cells has revealed that many of the components necessary for SV release are also necessary for DCV exocytosis. First it has been shown that the same SV SNAREs were necessary (Xu et al., 1998). Subsequently, the need for Munc18-1, synaptotagmins, Munc13-1, complexin, tomosyn and CAPS have also been elucidated for DCV secretion (Voets et al., 2001; Schonh et al., 2008; Ashery et al., 2000; Cai et al., 2008; Yizhar et al., 2004; Liu et al., 2010). Interestingly, a new specific role of CAPS function at the TGN has been suggested (Sadakata et al., 2010). It was shown that CAPS also localizes to the cell body and regulates DCV release through an interaction with many Golgi localized proteins such as Arf GTPases (Sadakata et al., 2010).

## 6.3 DCV biogenesis and maturation

Despite similarities in their exocytic machinery, SV and DCV turnover occurs through entirely different mechanisms. After release SVs are recycled through local endocytosis (Südhof, 2004). DCVs, on the other hand, must be synthesized *de novo* at the TGN (Kim et al., 2006; Morvan and Tooze, 2008). At the TGN, DCVs are initially generated in an immature form (iDCVs). Prior to reaching the synapse, these iDCVs undergo a maturation process whereby neuropeptides are retained and lysosomal enzymes, M6P receptors and constitutive secretory cargo is removed (Fig. VI.4). The removal of components during maturation is thought to occur through clathrin coated vesicle (CCV) sorting (Tooze et al., 2001; Lui-Roberts et al., 2005). Before maturation into mDCVs, iDCVs also undergo a process of homotypic fusion where vesicle size is increased or decreased (Tooze et al., 1991). Interestingly several proteins have been identified specifically to localize to iDCVs and not on mDCVs: Syntaxin 6, VAMP 4 and Synaptotagmin IV (Wendler et al., 2001; Eaton et al., 2000). Additionally, during the process of maturation, iDCVs are acidified and

**Figure VI.4. DCV maturation.** Before reaching the synapse DCVs must undergo a maturation process. Maturation of iDCVs to mDCVs requires the retention of neuropeptides, and respective processing enzymes and parallel removal of cargo such as lysosomal hydrolases and M6P receptors. Removal of components is suggested to occur via a CCV pathway to the endosomes. During maturation the size of iDCVs becomes larger or smaller as a consequence of homotypic fusion events (Tooze et al., 2001). Source: Picture taken and adapted from Tooze et al., 2001.

propeptides are cleaved at mono- or di-basic residues (-K / -R) through the action of proprotein convertases to form active peptides (Rouille et al., 1995). This endoproteolysis produces short peptides with C-terminal basic residues, which are subsequently cleaved by carboxypeptidase E (Rouille et al., 1995).

#### 6.4 DCVs function to regulate synaptic transmission

Although, it is clear that DCVs are modulators of synaptic transmission, the precise function of their peptide load remains to a large extent unknown. There are approximately 100 neuropeptide encoding genes identified in the human genome (Burbach, 2010). Recent work has suggested that certain neuropeptides can alter spontaneous and evoked release of SVs through a G-protein coupled receptor (GPCR) pathway. In this model, neuropeptides would activate a  $G\alpha_q$ -PLC pathway (in a manner similar to monoamine neurotransmitters). This would consequently lead to the increased production of DAG and  $IP_3$  from  $PIP_2$  (Perez-Mansilla and Nurrish, 2009; Lackner et al., 1999). Since Munc13 contains a phorbol ester-binding domain, increased DAG levels lead to an increased level of SV release (Rhee et al., 2002; Lou et al., 2008). This stimulation of SV release is counter-balanced by a  $G\alpha_o$  pathway

**Figure VI.5. Regulation of SV release by GPCRs.** Neuropeptides are thought to activate the Gαq-PLC pathway, which leads to an increased production of DAG. DAG consequently binds to the C1 domain of UNC-13 and potentiates SV release. This pathway is counterbalanced by a Gαo pathway and DGK-1 (*C.e* orthologue of DAG kinase). DGK-1 phosphorylates DAG to generate phosphatidic acid (PA). Note that these pathways can also be activated by monoamine neurotransmitters (Perez-Mansilla and Nurrish, 2009). Source: Picture taken and adapted from Perez-Mansilla and Nurrish, 2009.

and DAG kinase (DGK) which downregulates DAG levels. Figure VI.5 illustrates this pathway depicting the *C. elegans* orthologues of the molecules involved (many of the components were identified initially through screens in *C. elegans*) (Perez-Mansilla and Nurish, 2009). To date, the molecular identity of the neuropeptide GPCR of this pathway remains elusive and is a topic of much attention.

### 6.5 Studying DCV function in *C. elegans*

*C. elegans* has proven to be a useful system for the genetic dissection of DCV function. Like in the mammalian system, approximately 100 neuropeptide precursor genes have been identified in the nematode genome. Furthermore, much of the protein machinery involved in DCV maturation and release is conserved (Li and Kim, 2008). Recently a fluorescent-based assay to study DCV function *in vivo* has been developed in *C. elegans* (Fig.VI.6) (Sieburth et al., 2007). A neuropeptide (NLP-21) tagged to yellow fluorescent protein (YFP) is expressed in *C. elegans* DA and DB cholinergic motor neurons. The NLP-21-YFP is packaged into DCVs and transported to the NMJ. Prior to reaching the synapse, like other neuropeptides, NLP-21 is cleaved from the proform into the short bioactive form through the action of proprotein convertases

A

B

**Figure VI.6. Studying DCV function in *C. elegans*.** A. DCV trafficking can be studied using a fluorescence-based assay in *C. elegans*. A construct containing neuropeptide tagged to YFP (NLP-21-YFP) is used. NLP-21 is processed like other peptides and packaged into DCVs. B. NLP-21 is expressed in the cholinergic motor neurons of the worm (using the *unc-129* promoter). NLP-21-YFP is trafficked to the DNC NMJs and released into the body cavity. Scavenger cells called coelomocytes endocytose the YFP. Fluorescence intensity in the coelomocytes is used as an indirect readout of secretion. Fluorescence intensity in the DNC is also analyzed to measure the transport of DCVs to the NMJ. Scale bar in DNC represents 6  $\mu\text{m}$  and bar in coelomocytes is 3  $\mu\text{m}$  (Sieburth et al., 2007). Source: Pictures taken and adapted from Gracheva et al., 2007; Sumakovic et al., 2009.

(EGL-3) and carboxypeptidase E (EGL-21). After DCV maturation the NLP-21-YFP peptides are released into the synaptic extracellular milieu (ECM). *C. elegans* possesses 6 macrophage-like cells called coelomocytes which continuously filtrate the body fluid of the pseudocoelom through bulk endocytosis. The amount of YFP endocytosed by these coelomocytes can be measured as an indirect reporter of DCV secretion levels. Additionally YFP levels can, in parallel, be measured in the synapses of the motor neurons to analyze DCV trafficking (Sieburth et al., 2007). Strikingly, most mutants, which displayed defects in DCV release in the mammalian system, have also been detected through this assay: CAPS (*C.e* UNC-31), Munc-13 (*C.e* UNC-13), tomosyn (*C.e* TOM-1) (Sieburth et al., 2007; Gracheva et al., 2007).

In a previous project from our laboratory, this assay was used to detect a DCV maturation defect in *rab-2* mutants in *C. elegans* (Sumakovic et al., 2009). To our surprise, *rab-2* mutants displayed a genetic interaction with *rab-5* in DCV function. This led us to believe that multiple RAB GTPases may coordinate together to regulate DCV trafficking.

## VII. AIMS

A large cohort of proteins are necessary for the regulation of DCV function. Some of these molecules, such as Munc18 and Munc13 were first identified in *C. elegans* (Maruyama and Brenner, 1991; Hosono et al., 1992; Brenner, 1974). The recent development of novel *in vivo* imaging assays has permitted more rigorous analyses of DCV function in *C. elegans* (Fig. VI.6) (Sieburth et al., 2007). Although, the NLP-21-YFP assay developed by Sieburth et al. is an indirect means to measure DCV function, many previously identified factors involved in DCV secretion were shown defective also in NLP-21-YFP secretion: CAPS (*C.e* UNC-31), Munc-13 (*C.e* UNC-13), tomosyn (*C.e* TOM-1) (Sieburth et al., 2007; Gracheva et al., 2007).

This assay recently allowed for the elucidation of RAB-2 as a regulator of DCV function (Sumakovic et al., 2009; Edwards et al., 2009). *rab-2* mutants displayed decreased NLP-21-YFP levels in the DNC compared to wild type animals (approximately 20% of wild type). Since RAB-2 localizes to the Golgi, it was established that it plays an early role in the maturation of DCVs by ensuring that necessary cargo is retained (Sumakovic et al., 2009; Edwards et al., 2009). In *rab-2* mutants, it was thought that there is a loss of DCV cargo into the endo-lysosomal system. Therefore, to block this loss of cargo, a constitutively active mutant of *rab-5* (*Q78L*) was overexpressed in a *rab-2* mutant background. Interestingly, the *rab-5* (*Q78L*) suppressed the decreased levels of NLP-21-YFP in the DNC of *rab-2* mutant animals (Fig. VII.1). These results showed, for the first time, that RAB GTPases cooperate in regulating DCV trafficking in *C. elegans*.

Considering that there are 28 RABs encoded in the *C. elegans* genome and that mutants for these RABs were available, we aimed to determine novel Rabs involved in the regulation of DCV secretion. Since we had mutants for several

**Figure VII.1. A *rab-5* mutant suppresses DCV defects in *rab-2* mutants.** *rab-2* mutants were found to display a defect in DCV maturation. The NLP-21-YFP levels in these strains were strongly decreased in the DNC. Strikingly when a constitutively active *rab-5* (*Q78L*) mutant was expressed in a *rab-2* mutant background, the NLP-21-YFP levels in the DNC returned to wild type levels. Scale bar in DNC represents 8  $\mu$ m. Error bars = SEM (\*\*\*,  $P < 0.005$  ANOVA with Bonferroni post test) (Sumakovic et al., 2009) Source: This experiment was not conducted in this study and is only used as a means to explain the rationale of the project. The original data for this figure was kindly provided by Marija Sumakovic.

regulators of RAB function (TBC domain containing RABGAPs), we also analyzed the role of these molecules in DCV secretion. After identification of new RABs and RABGAPs, we determined if they were DCV-specific regulators or if they were also involved in the regulation of SV secretion. As a last step we investigated how the function of all molecules may be integrated together to regulate secretion.

It must be mentioned that most experiments in this chapter were done together by the author and by Marija Sumakovic, as this was a shared project. The author was involved together with Marija Sumakovic in conducting experiments and producing the data for every figure, unless otherwise stated in the figure legend.

## VIII. RESULTS

### 8.1 RAB-5 and RAB-10 are novel RABs essential for DCV release

In order to identify if additional RABs were involved in DCV trafficking we tested all *rab* mutants through the NLP-21-YFP assay (Fig. VIII.1). The *rab* genes with no available mutant, were tested by RNAi knockdown and data from *glo-1* and *rab-y1* to *rab-y6* were excluded for simplicity. Please note that knockdown of lethal genes (*rab-1*, *rab-7*, *rab-11.1*) were conducted using a tissue specific RNAi technique to bypass the lethality and analyze adult worms. This technique is described in section 8.2. A *rab-5 (Q78L)* was used since it was available from a previous study (Sumakovic et al., 2009). Analysis revealed that both, an overexpression of *rab-5 (Q78L)* and the *rab-10* deletion mutants displayed severe defects in NLP-21-YFP release. In contrast to *rab-2* mutants, the *rab-5 (Q78L)* and the *rab-10* mutants had wild type levels of YFP in the DNC, but drastically decreased levels in the coelomocytes. Coelomocyte fluorescence levels were  $16.76 \pm 0.04\%$  and  $0.00 \pm 0.00\%$  in *rab-5 (Q78L)* and *rab-10* mutants respectively when compared to wild type. *unc-31* mutants were used as a control and displayed a significant increase in the DNC with  $159.60 \pm 0.18\%$  and a significant decrease in the coelomocytes to  $30.36 \pm 0.08\%$  of wild type. From this point on, the overexpressed *rab-5 (Q78L)*, will be referred to as *rab-5 (Q78L)* mutants. To ensure that the defects that we observed were cell autonomous, we generated transgenic lines of *rab-10* mutants expressing *mCherry-rab-10* in the cholinergic DA and DB motor neurons. Transgenic lines rescued the YFP intensity levels in the coelomocytes of *rab-10* mutants, supporting the idea that RAB-10 is indeed a regulator of DCV secretion (data not shown).

**Figure VIII.1. NLP-21-YFP analysis of all *rabs*.** The trafficking of NLP-21-YFP was analyzed for all *rab* mutants. The assay revealed that *rab-5* (*Q78L*) and *rab-10* mutants display a severe defect in DCV release. Scale bar in DNC represents 6  $\mu\text{m}$  and bar in coelomocytes is 3  $\mu\text{m}$ . At least  $N = 10$  animals were tested per strain. Error bars = SEM (\*\*\*,  $P < 0.005$ ; \*\*,  $P < 0.01$ , \*,  $P < 0.05$  ANOVA with Bonferroni post test). Note: RNAi experiments were normalized to mock, L4440, knockdown.

## 8.2 DCV trafficking defects are autonomous to the nervous system

### 8.2.1 Development of a neuron-specific RNAi system

NLP-21-YFP analysis revealed that *rab-5* (*Q78L*) and *rab-10* mutants have defects in DCV release. Since rescue experiments were only feasible with *rab-10* mutants and not *rab-5* (*Q78L*) mutants, we developed a neuron-specific RNAi technique to determine cell-specificity of the observed DCV release defects.

**Figure VIII.2. Validation of neuron-specific RNAi.** Neuron-specific knockdown was achieved using an *rde-4* mutant, which is deficient in RNAi. These mutants were rescued with *rde-4* expression only in the DA and DB motor neurons using the *punc-129* promoter (Note: transgenic animals express *pttx-3::gfp* in head neurons. This was used as a co-injection marker). All RNAi experiments were done in the classical *eri-1* background for enhanced sensitivity to RNAi and also in the *nuls183* background, *nuls183* expresses GFP in the pharynx (selection marker) and NLP-21-YFP (assay marker). Knockdown of GFP revealed that RNAi was neuron-specific. Scale bar in pharynx represents 50  $\mu$ m and bar in DNC is 6  $\mu$ m. Error bars = SEM (\*\*\*, P < 0.005; ANOVA with Bonferroni post test)

RDE-4 encodes a double stranded RNA binding protein, which is important for stabilizing DNA for recognition by dicer. *rde-4* (*RNAi deficient-4*) mutant animals exhibit an inability to carry out RNAi (Duchaine et al., 2006). Therefore, using an *rde-4* mutant background, we transgenically rescued *rde-4* expression only in the DA and DB cholinergic motor neurons. This strain was then crossed into an *eri-1* background (classical mutant background with increased RNAi sensitivity) and also the NLP-21-YFP assay strain (*nuIs183*) (Timmons, 2004; Sieburth et al., 2007). The *nuIs183* strain expresses GFP in the pharynx (*myo-2* promoter) and the NLP-21-YFP in the DA and DB cholinergic motor neurons (*unc-129* promoter). To validate if the tissue-specific RNAi was working, we conducted a control experiment knocking down GFP. Knockdown of GFP just in the *eri-1; nuIs183* background led to significantly decreased XFP levels in the pharynx and the DNC. Fluorescence intensity was decreased to  $0.83 \pm 0.58$  % and  $11.76 \pm 3.75$  % in the pharynx and DNC respectively when compared to knockdown with a mock vector (L4440). Surprisingly, knockdown of GFP in the tissue specific RNAi strain, *eri-1; rde-4; nuIs183 Ex[punc-129::rde-4]*, lead to no significant decrease of XFP levels in the pharynx, but a reduction in the dorsal nerve cord. Fluorescence intensity values were  $85.31 \pm 2.57$  % and  $15.89 \pm 6.10$  % in the pharynx and DNC respectively when compared to L4440 knockdown (Fig.VIII.2).

### 8.2.2 RAB-5 and RAB-10 cell-specifically regulate DCV release

After having validated that the neuron-specific RNAi strain was working. We tested if we could phenocopy the *rab-5* (*Q78L*) and *rab-10* mutant phenotypes using RNAi. Interestingly, knockdown of *rab-5* and *rab-10* in the cholinergic motor neurons led to a similar significant decrease in fluorescence levels in the coelomocytes and normal levels in the DNC. Knockdown of *rab-5* and *rab-10* led to coelomocyte fluorescence intensities of  $12.78 \pm 0.05$  % and  $0.01 \pm 0.00$  % respectively compared to mock (Fig. VIII.3). This suggested that RAB-5 and RAB-10 play a cell autonomous function in regulating DCV secretion. Interestingly, further evidence which suggested that our tissue-specific RNAi was working was the ability of *rab-5* RNAi animals to bypass lethality. Normal knockdown of *rab-5* leads to late embryonic lethality.

**Figure VIII.3. Neuron-specific knockdown of *rab-5* and *rab-10*.** Knockdown of *rab-5* and *rab-10* in the cholinergic motor neurons phenocopied the DCV secretion defect observed in the respective mutants. Scale bar in DNC represents 6  $\mu\text{m}$  and bar in coelomocytes is 3  $\mu\text{m}$ . Error bars = SEM (\*\*\*,  $P < 0.005$ ; ANOVA with Bonferroni post test)

### 8.3 Identification of RAB regulators involved in DCV release

In order to identify novel molecules involved in the regulation of DCV secretion, it was decided to screen regulators of RAB GTPases. Since RAB function is regulated by GEFs and GAPs, we focused on these two families of proteins. At the time of this experiment, more *C. elegans* RAB GAP mutants were available than RAB GEF mutants. Therefore, all neuronally expressed TBC (*tre-2/cdc16/Bub2*) domain containing RABGAP mutants were screened through the NLP-21-YFP assay (all data not shown). Interestingly, analysis revealed that two Rab GAP mutants displayed similar defects to *rab-5* (*Q78L*) and *rab-10* mutants. Two mutant alleles of *tbc-2* were tested: *tbc-2* (*qx20*) and *tbc-2* (*tm2241*) had coelomocyte fluorescent intensities of  $28.64 \pm 14.10\%$  and  $18.99 \pm 4.00\%$ , respectively, of wild type. Two mutant alleles of *tbc-4* were also tested: *tbc-4* (*ok2928*) and *tbc-4* (*tm3255*) had coelomocyte fluorescent intensities of  $5.36 \pm 2.10\%$  and  $4.18 \pm 1.39\%$  of wild type. DNC intensity levels of these mutants were unchanged (Fig.VIII.4).

**Figure VIII.4. TBC-2 and TBC-4 are novel regulators of DCV secretion.** A screen of all mutants containing (Tre-2/Cdc16/Bub2) domains revealed that *tbc-2* and *tbc-4* mutants are defective in NLP-21-YFP release. Two different alleles of *tbc-2* and *tbc-4* were tested. To demonstrate cell-specificity of the observed phenotype, *tbc-4* mutants were rescued by expressing *tbc-4* exclusively in neuron (using the *rab-3* promoter). To show that the rescue was dependent on the TBC domain, a catalytically inactive R155A mutant of *tbc-4* was also tested. Scale bar in DNC represents 6  $\mu$ m and bar in coelomocytes is 3  $\mu$ m. Error bars = SEM (\*\*\*,  $P < 0.005$ ; ANOVA with Bonferroni post test)

To demonstrate that the phenotype of *tbc-4* mutants was cell-type specific, we conducted neuron-specific (with *rab-3* promoter) rescue experiments. Neuron-specific rescue restored coelomocyte fluorescence intensities back to wild type levels. To determine if the regulatory function of TBC-4 was dependent on its catalytic domain, we tested a catalytically inactive mutant, *tbc-4* R155A, for rescue. Interestingly, the *tbc-4* R155A, was unable to rescue *tbc-4* mutants suggesting that the role of TBC-4 in DCV secretion is indeed dependent on its ability to regulate the catalytic activity of a RAB (Fig.VIII.4)

#### 8.4 RAB-5, TBC-2, RAB-10 and TBC-4 also affect secretion of INS-22

From the results of the NLP-21-YFP assay it was clear that RAB-5, TBC-2, RAB-10 and TBC-4 are important for the secretion of NLP-21-YFP. However, to rule out the possibility that the observed defect was limited only to NLP-21, we also tested a second DCV marker, INS-22-YFP. In accordance with the NLP-21-YFP results, all four mutants showed decreases in INS-22-YFP in coelomocytes (Fig. VIII.5). *rab-5* (*Q78L*), *tbc-2* (*tm2241*), *rab-10* (*ok1494*) and *tbc-4* (*ok2928*) had coelomocyte fluorescence intensities  $48.53 \pm 5.86 \%$ ,  $30.10 \pm 8.71 \%$ ,  $7.98 \pm 3.16 \%$  and  $2.82 \pm 0.31 \%$  respectively. It is interesting to note that a trend observed so far is that the *rab-5* and the *tbc-2* mutants display slightly weaker phenotypes than the *rab-10* and *tbc-4* mutants.

**Figure VIII.5. *rab-5* (*Q78L*), *tbc-2*, *rab-10* and *tbc-4* mutants also have defects in INS-22 secretion.** In order to verify if the observed defects in DCV secretion were limited to NLP-21-YFP, a second neuropeptide marker, INS-22-YFP was also analyzed. In accordance with the NLP-21-YFP data, mutants of all four genes displayed defects in INS-22-YFP release. Scale bar in DNC represents 6  $\mu\text{m}$  and bar in coelomocytes is 3  $\mu\text{m}$ . Error bars = SEM (\*\*\*,  $P < 0.005$ ; \*,  $P < 0.01$  ANOVA with Bonferroni post test)

### 8.5 Endocytosis in coelomocytes is not affected

Both the NLP-21-YFP and INS-22-YFP assays rely on coelomocyte endocytosis of YFP as reporter. To ensure that the observed defects were indeed due to altered DCV release and not due to altered coelomocyte endocytosis, we examined the integrity of coelomocyte endocytosis. This was tested through the injection of soluble Texas-Red conjugated to bovine serum albumin (TR-BSA), into the worm body cavity. In wild type animals, the TR-BSA is readily endocytosed by the coelomocytes and enters early endosomes (labeled with RME-8-GFP marker) within the first 5 minutes post injection. The dye then starts to migrate out of the RME-8-GFP positive endosomes and onto late endosomes after 30 minutes. Usually after 45-50 minutes almost all of the TR-BSA is found in the late endosomes. *rab-5 (Q78L)*, *tbc-2 (tm2241)*, *rab-10 (ok1494)* and *tbc-4 (ok2928)* were all tested by TR-BSA injection and results showed that the ability of these mutants to endocytose and the kinetics of endocytosis were unaltered (Fig. VIII.6).

### 8.6 Synaptic vesicle release is not affected

#### 8.6.1 Analysis of SV markers: SNB-1 and RAB-3

The TR-BSA endocytosis assay signified that RAB-5, TBC-2, RAB-10 and TBC-4 are factors required for DCV secretion. Since, it has been shown that much of the DCV secretion machinery is also necessary for SV release, we verified if our molecules of interest were also important for SV exocytosis. This was first studied by imaging two different SV markers: GFP-Synaptobrevin and YFP-RAB-3. These markers were expressed in the cholinergic motor neurons (DA and DB). In the neurons, both markers localize to SVs at the DNC synapse and can be viewed as discrete puncta. Each puncta is thought to correspond to the presynapse of a neuromuscular synapse (Sieburth et al., 2005). Fluorescence intensities of puncta, number of puncta and puncta size of GFP-SNB-1 and YFP-RAB-3 were measured for *rab-5 (Q78L)*, *tbc-2*, *rab-10* and *tbc-4* mutants. Interestingly, analysis of both SV markers revealed no significant changes suggesting that SVs were localized correctly and were unaffected (Fig VIII.7).

**Figure VIII.6. Assessment of coelomocyte function through TR-BSA injection.** Analysis of *rab-5* (Q78L), *tbc-2*, *rab-10* and *tbc-4* mutants to endocytose TR-BSA showed that these mutants had no defects in the ability to endocytose or in the kinetics of endocytosis. RME-8-GFP was used as an early endosomal marker. TR-BSA (Red) and RME-8-GFP (Green). Scale bar represents 5  $\mu$ m.

**Figure VIII.7. Analysis of SV markers.** **A.** GFP-SNB-1 fluorescence levels were unchanged in *rab-5* (*Q78L*), *tbc-2*, *rab-10* and *tbc-4* mutants. Additionally, the number and size of GFP-SNB-1 puncta were also unaffected in these mutants. **B.** YFP-RAB-3 fluorescence levels were unchanged in *rab-5* (*Q78L*), *tbc-2*, *rab-10* and *tbc-4* mutants. Additionally, the number and size of YFP-RAB-3 puncta were also unaffected in these mutants. Scale bar in DNC represents 6  $\mu\text{m}$ . Error bars = SEM (ANOVA with Bonferroni post test).

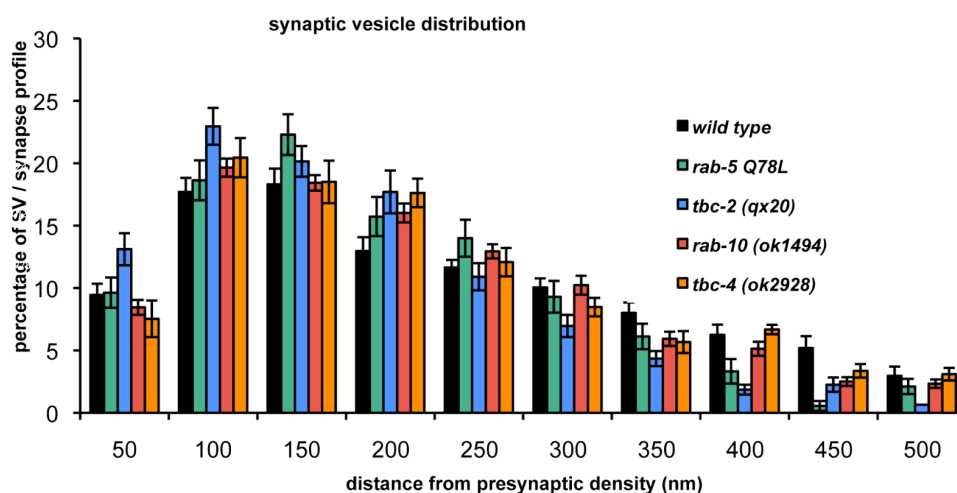

### 8.6.2 EM analysis of SV distributions in synapses

The analysis of GFP-SNB-1 and YFP-RAB-3 markers was limited to the resolution of the confocal microscope. In order to assess, at high resolution, the integrity of synapses, we analyzed *rab-5* (*Q78L*), *tbc-2*, *rab-10* and *tbc-4* mutants using high-pressure freeze electron microscopy (HPF-EM). An overall morphological observation of mutant synapses revealed that mutant synapses were largely similar to wild type (Fig. VIII.8). Some *rab* mutants, such as *rab-3*, have been shown to display altered SV distributions in synapses as a result of a tethering defect. In order to determine if *rab-5*, *rab-10*, *tbc-2* and *tbc-4* mutants had similar defects in tethering,

A

B

Genotype	Number of profiles / animal analyzed	Mean synaptic area	SV / profile	Mean diameter of SV	DCV / profile	Mean diameter of DCV
<i>wild type</i>	80 / 8	0.21 ± 0.01	33.7 ± 1.6	31.2 ± 0.4	2.1 ± 0.2	44.3 ± 0.7
<i>rab-5 Q78L</i>	47 / 3	0.18 ± 0.01	30.1 ± 1.5	30.7 ± 0.4	2.3 ± 0.5	44.9 ± 0.9

we analyzed the distribution of SVs from the active zone in the mutant synapses. Statistical analysis showed that SV distributions were also unaffected (Fig. VIII.8). From the same synapses, the number and size of DCVs were also analyzed and appeared like wild type.

### 8.6.3 EM analysis of neuron morphology

After confirming that the neuronal synapses and the SV distributions were normal, we analyzed the neuronal cell bodies of *rab-5 (Q78L)*, *tbc-2*, *rab-10* and *tbc-4* mutants to verify if there were any upstream changes, which may affect nervous system function. Neuronal cell somas and neuronal Golgis were analyzed by HPF-EM for each mutant. Results revealed that all four mutants had no obvious abnormalities in neuronal morphology (Fig. VIII.9).

### 8.6.4 Electrophysiological analysis of synaptic transmission

Both confocal and EM data showed that there were no defects in SV localizations, synapse morphology and neuron morphology. In order to determine if there was any changes in SV exocytosis, we measured excitatory postsynaptic currents (EPSCs) at the NMJs by whole cell patch clamp. This experiment was done in collaboration with Alexander Gottschalk's lab, Johann Wolfgang Goethe University in Frankfurt. All *rab-5 (Q78L)*, *tbc-2*, *rab-10* and *tbc-4* mutants were crossed into a strain expressing channelrhodopsin-2 in the cholinergic motor neurons. Photo-evoked responses revealed that there were no changes in EPSCs (Fig. VIII.10). These results indicated that *rab-5 (Q78L)*, *tbc-2*, *rab-10* and *tbc-4* mutants are most likely factors involved in DCV release and not SV exocytosis.

## 8.7 TBC-4 is a potential GAP for RAB-10

Considering the strong similarity in phenotypes between *rab-5 (Q78L)*, *tbc-2*, *rab-10* and *tbc-4* mutants, an obvious interpretation is that TBC-2 and TBC-4 may be GAPS for RAB-5 and RAB-10. In line with this, a very recent study showed that TBC-2 is indeed the GAP for RAB-5 (Chotard et al., 2010). This was revealed through an *in vitro* GAP assay with recombinant RAB-5 and TBC-2 purified from *E.coli*. These results led us to believe that TBC-4 could potentially be the GAP for RAB-10. Although, it was possible to purify TBC-4, attempts to recombinantly purify RAB-10 in *E.coli* failed. Thus, in the meantime, we attempted a yeast-2-hybrid (Y2H) strategy to show the substrate specificity of TBC-4. Since RAB-GAP interactions are in the order of 200  $\mu$ M (personal communication with Aymelt Itzen, MPI for Molecular Physiology), it is difficult to detect such transient interactions. A previous study by Francis Barr's lab showed that RAB-GAP interactions could be

**Figure VIII.9. HPF-EM analysis of neuron morphology.** Morphological analysis of *rab-5 (Q78L)*, *tbc-2*, *rab-10* and *tbc-4* mutant neurons and their Golgis revealed that there were no obvious defects. detected through Y2H (Haas et al., 2005). However, for capturing such interactions the catalytic arginine residue of the GAP must be mutated to alanine. This enabled Haas et al., to show that Rabgap-5 is the GAP for Rab5 in mammals. We chose to use a similar approach to test TBC-4 and RAB-10. The TBC domain of TBC-4 is between residues 106 and 316 (SMART prediction). Additionally it contains four coiled coil (CC) domains (please see appendix for full protein sequence). The catalytic R155 was mutated to A and tested against a constitutively active RAB-10 (Q68L) as well as other *C. elegans* RABs. Surprisingly, results showed that RAB-10 binds to TBC-4 (R155A) in a GTP-dependent manner because the constitutively inactive RAB-10 (T23N) did not bind to TBC-4 (R155A) (Fig. VIII.11). This provided evidence that TBC-4 may indeed be a RAB-10 specific GAP. Through our interaction analysis we also found that TBC-4 binds two additional RABs: RAB-8 and RAB-11.1. Since these interactions were found also in the wild type TBC-4 and the TBC-4 R155A, it is likely that these RABs are binding to sites outside the TBC domain (Fig. VIII.11).

**Figure VIII.11. Y2H analysis of TBC-4 binding.** **A.** TBC-4 is a 825 aa protein, which contains multiple domains. The TBC domain (purple) is predicted to be between 106 to 316 aa. Additionally there are 4 coiled coil (CC) domains. Please see appendix for protein sequence. **B.** Y2H analysis showed that TBC-4 binds to RAB-8, RAB-10 and RAB-11.1. Strikingly the interaction with RAB-10 is dependent on the R155A mutation. **C.** The binding to TBC-4 was abolished in constitutively inactive RABs. Source: This experiment was conducted by the author and Mandy Hannemann.

Preliminary data suggests that they are binding to the N-terminal CC domain, which lies upstream of the TBC domain (data not shown).

### 8.8 Rabaptin-5 bridges RAB-5 and RAB-10 function

Since the phenotypes of RAB-5 and TBC-2 were surprisingly similar to RAB-5 and TBC-4, we hypothesized they belonged to the same pathway and function together to regulate DCV release. To answer this, we screened with Y2H all known RAB-5 effectors against RAB-10 and TBC-4 to identify if there were any common molecules. To our surprise, we found that Rabaptin-5 (RABN-5), a RAB-5 effector shown to be important in endosomal fusion (Stenmark et al., 1995), interacted with TBC-4. After testing different domains of TBC-4, it was identified that RABN-5 interacted with the C-terminal CC domains downstream of the TBC-domain (Fig. VIII.12).

**Figure VIII.12. Y2H analysis of TBC-4 interaction with RABN-5.** TBC-4 interacts with RAB-10 in a GTP dependent manner. Additionally the interaction occurs at the C-terminal coiled coil domains (377-825) of TBC-4. Source: This experiment was conducted by Mandy Hannemann and the data was kindly provided by her.

The Y2H interaction of RABN-5 with TBC-4 suggested that there may be a RAB cascade between RAB-5 and RAB-10 that is necessary for DCV function. Furthermore, RABN-5 would act as a bridging molecule between these two RABs. To verify if RABN-5 was also a regulator of DCV release, we tested the effect of RABN-5 knockdown on NLP-21-YFP secretion. Since the *rabn-5* locus is on the

same chromosome and in close proximity to the NLP-21-YFP insertion, we could not test the mutant. Therefore, we relied on neuron-specific RNAi. Interestingly, knockdown of *rabn-5* led to a decrease in NLP-21 secretion. Fluorescence intensity values were  $32.75 \pm 14.80\%$  compared to knockdown of mock, L4440 secretion (Fig. VIII.13). Intensity levels in the DNC were unchanged. Since RABN-5 has also been shown to be involved in the endocytic pathway (Stenmark et al., 1995), we wanted to verify if the observed defect of RABN-5 on NLP-21-YFP release was due to perturbation of endocytosis. Therefore, another molecule involved in early endocytic transport, early endosomal antigen-1 (EEA-1) (Simonsen et al., 1998), was knocked down by RNAi and analyzed for NLP-21-YFP secretion (Fig. VIII.13). Interestingly depletion of EEA-1 showed no defect, suggesting that the observed role of RABN-5 in DCV secretion is a novel secondary role of this protein. To confirm this we also tested *rabn-5* mutants in the INS-22-YFP secretion assay. In accordance with the NLP-21-YFP data, *rabn-5* mutants had coelomocyte intensities of  $43.13 \pm 3.71\%$  of wild type and normal levels of INS-22-YFP in the DNC (data not shown).

**Figure VIII.13. NLP-21-YFP analysis of RABN-5 and EEA-1.** Neuron specific RNAi of *rabn-5* showed a decrease in coelomocyte intensity levels suggesting a role in DCV release. Knockdown of another RAB-5 effector, *eea-1*, displayed no defect in DCV secretion. Scale bar in DNC represents 6  $\mu\text{m}$  and bar in coelomocytes is 3  $\mu\text{m}$ . Error bars = SEM (\*,  $P < 0.05$ ; ANOVA with Bonferroni post test)

### 8.9 EHBP-1 also regulates DCV release and interacts with RAB-10

During the course of this study, one of our collaborators had identified a novel RAB-10 effector in *C. elegans*, named EHBP-1 (Personal communication with Barth Grant, Rutgers's University, New Jersey). EHBP-1 contains a calponin homology (CH) domain and a CC domain. Firstly we verified the specificity of the RAB-10-EHBP-1 interaction, by Y2H screening of EHBP-1 against all *C. elegans* RABs. The full length EHBP-1 was tested as well as a shorter fragment containing only the CC domain. Interestingly, the full length EHBP-1 did not interact with any RABs and the shorter EHBP-1(662-901) interacted with RAB-8 and RAB-10 (Fig. VIII.14).

To determine if EHBP-1 is also involved together with RAB-10 in DCV secretion, we tested it through the NLP-21-YFP assay. The *ehbp-1* mutant is lethal, so we chose to test it through the neuron-specific RNAi strain. Results revealed that knockdown of *ehbp-1* leads to a severe defect in DCV release (Fig. VIII.14). The fluorescence intensity in coelomocytes was  $1.00 \pm 0.20$  % of the mock knockdown. This suggested that EHBP-1 is also involved in this pathway.

### 8.10 Colocalization analysis of novel factors involved in DCV release

Six different molecules were identified in this study to participate specifically in DCV secretion: RAB-5, TBC-2, RAB-10, TBC-4, RABN-5 and EHBP-1. To determine where these molecules function in the cell, a sub-cellular localization analysis was done. Proteins of interest were tagged with fluorescent proteins and co-injected with compartmental markers. Since, the localization of RAB-5 and TBC-2 to the endo-lysosomal system has already been well characterized in *C. elegans* (Chotard et al., 2010), we started by focusing on RAB-10. The localization of RAB-10 with respect to ER (CB5-GFP), COPI coat (GFP- $\epsilon$ COP), Golgi (MANNSII-YFP), Endosomes (GFP-2xFYVE), iDCVs/endosomes (tagRFP-SYX-6) and synapses (GFP-SNB-1 and YFP-RAB-3) was verified (Fig. VIII.15). Co-localization analysis revealed that RAB-10 puncta are detectable in the neuronal cell soma and at the synapse. In the soma, RAB-10 showed a partial overlap with Golgi and endosomal markers. At the synapses, RAB-10 showed almost full colocalization with SNB-1 and RAB-3. However, the SV markers appeared more concentrated and brighter whereas RAB-10 staining was weaker and diffuse. This suggests that RAB-10 could

**A** EHBP-1:

EHBP-1 (662-901):

**B**

**Figure VIII.14. Y2H and NLP-21-YFP analysis of a RAB-10 effector.** **A.** The full length EHBP-1 did not interact with any Rabs. A shorter fragment, which included the CC domain (662-901), interacted with RAB-10 and RAB-8. **B.** Neuron specific RNAi of *ehbp-1* showed a decrease in coelomocyte intensity levels. Scale bar in DNC represents 6  $\mu$ m and bar in coelomocytes is 2.5  $\mu$ m. Error bars = SEM (\*\*\*,  $P < 0.005$ ; ANOVA with Bonferroni post test)

**Figure VIII.15. Fine mapping of the sub-cellular localization of RAB-10 in neurons.** A detailed analysis of the sub-cellular localization of RAB-10 showed that it was localized to discrete puncta in the neuronal cell soma and at the synapses of DNC. Neuronal cell somas from the VNC were chosen for imaging and each picture depicts two neuronal cell bodies. In the cell bodies, RAB-10 showed partial colocalization with Golgi and endosomal markers, but no full colocalization with any of the markers tested. At the synapses, RAB-10 showed a complete localization with SNB-1 and RAB-3. However, the RAB-10 staining was less concentrated than the SV markers. Note: GFP-RAB-10 and tagRFP-SYX-6 are false colored to enable simpler viewing. Scale bar in somas is 4  $\mu\text{m}$  and DNC is 5  $\mu\text{m}$ .

be localizing to DCVs, since there are fewer DCVs than SVs at *C. elegans* synapses (Fig. VIII.8).

After having analyzed the localization of RAB-10, the localization of the RAB-5 (Q78L), TBC-2, RABN-5, TBC-4 and EHBP-1 was elucidated. RAB-5 (Q78L) localized on domains adjacent to RAB-10. TBC-4 had a full overlap with RAB-10, which is in accordance with the previous data that it is a potential GAP for RAB-10. Additionally, TBC-4 showed a full colocalization with RABN-5. This is also in accordance with the previous Y2H binding data. EHBP-1 had a rather diffuse and tubular staining, but it did show a partial overlap with RAB-10 (Fig. VIII.16).

**Figure VIII.16. Sub-cellular localization analysis of RAB-5 (Q78L), TBC-4, RABN-5 and EHBP-1.** All images were taken of neurons from the VNC. RAB-5 (Q78L) appeared to localize adjacent to RAB-10. TBC-4 displayed full colocalization with RAB-10. A significant amount of TBC-4 was also cytosolic. RABN-5 and RABN-5 also showed a full overlap in localization. EHBP-1 and RAB-10 displayed a partial overlap. EHBP-1 staining was diffuse and tubular in the neuronal cell bodies. Note: GFP-RAB-10, mCherry-RAB-5 (Q78L), tagRFP-TBC-4 and EHBP-1-tagRFP were false colored to allow simpler viewing. Scale bar in somas is 4  $\mu$ m.

This concludes the experiments conducted during the course of this study. The results point towards the existence of a RAB cascade necessary for DCV secretion whereby RAB-5 recruits TBC-4 via RABN-5. After recruitment, TBC-4 would then exclude RAB-10 from nearby membranes allowing for mDCVs to form. Details of this cascade can be found in the IX. Chapter 2: Discussion section. Further experiments are ongoing to elucidate the mechanism of this process.

## IX. DISCUSSION

### 9.1 RAB-5 and RAB-10 are novel regulators of DCV secretion

RAB GTPases are master regulators of membrane trafficking. To understand the role of RABs in regulating DCV release, we took advantage of a novel *in vivo* fluorescence based assay to study DCVs in *C. elegans* (Sieburth et al., 2007). In wild type animals NLP-21-YFP is secreted from the motor neurons into the ECM. Consequently, macrophage-like cells called coelomocytes endocytose the YFP. Secretion of YFP can be indirectly quantified by means of fluorescence intensities in the coelomocytes. Although, this is an indirect measure of secretion, previously identified molecules involved in DCV release in mammalian cells have also been shown to be defective in NLP-21-YFP secretion: CAPS (*C.e* UNC-31), Munc-13 (*C.e* UNC-13), tomosyn (*C.e* TOM-1) (Sieburth et al., 2007; Gracheva et al., 2007). Furthermore, this assay is amenable for conducting larger scale analyses of multiple mutants. Therefore we tested all available *rab* mutants through this assay to study the role of RABs in regulating DCV function.

Analysis of all *rab* GTPase mutants showed that constitutively active *rab-5 Q78L* and *rab-10* mutants had severe defects in NLP-21-YFP secretion. These results were further confirmed by testing with a second DCV marker, INS-22-YFP, suggesting these mutants have a general defect in DCV secretion. To ensure that the observed defect was cell-autonomous in neurons we developed a neuron-specific RNAi technique. In accordance with the analysis of the mutants, neuron-specific knockdown of *rab-5* and *rab-10* also suggested that they are essential for DCV release. Since the RNAi results of *rab-5* phenocopied *rab-5 Q78L*, for simplicity the *rab-5 Q78L* mutants will be referred to as *rab-5* mutants for the remainder of the discussion.

Unlike the *unc-31* (CAPS) mutants, which also have a defect in DCV secretion, the *rab-5* and *rab-10* mutants displayed no buildup of unsecreted YFP at the synapses. Rather, the fluorescence intensities at the DNCs of these mutants were like wild type. An explanation for this stems from the finding that *de novo* DCV biogenesis is genetically regulated by a DCV transmembrane protein, IA2/ICA512, through a feedback mechanism (Trajkovski et al., 2008). Upon fusion, the cytoplasmic tail of IA2/ICA512 is cleaved and translocates to the nucleus to positively regulate the expression of DCV proteins (Trajkovski et al., 2008). In the absence (or severe decrease) of fusion, like in *rab-5* and *rab-10* mutants, such a feedback loop could be inhibited. This would consequently arrest the production of new DCVs, preventing an accumulation at synapses. *C. elegans* has a single orthologue of IA2/ICA512 called IDA-1 and interestingly, it has been recently shown to localize to DCVs in neurons and to be involved in the regulation of DCV genes (Cai et al., 2009).

In order to identify novel molecules that may function together with RAB-5 and RAB-10 we analyzed the TBC-domain containing family of proteins, which act as regulators of RAB GTPase function. Screening of all available neuronally expressed *tbc* mutants showed that *tbc-2* and *tbc-4* are also involved in the DCV secretion pathway. To distinguish whether RAB-5, TBC-2, RAB-10 and TBC-4 were specific regulators of DCV release and not SV release, we analyzed the SVs in these mutants. Examination of fluorescent synaptic markers (GFP-SNB-1 and YFP-RAB-3) showed that *rab-5*, *tbc-2*, *rab-10* and *tbc-4* mutants had no changes in the amount of SVs, the size of synapses or the number of synapses. Ultrastructural analysis of these mutants further revealed that the numbers of SVs were normal and that the distribution of SVs from the active zone were unchanged. Measurement of EPSCs revealed that evoked SV release was also unaffected in *rab-5*, *tbc-2*, *rab-10* and *tbc-4* mutants. This suggested that RAB-5, TBC-2, RAB-10 and TBC-4 were indeed specific regulators of DCV exocytosis and not SV release.

Considering the results that were obtained, we had hypothesized that TBC-2 and TBC-4 may function as GAPs for RAB-5 and RAB-10. Interestingly, in line with this prediction, recent *in vitro* studies showed that TBC-2 displayed GAP activity specifically for RAB-5 (Chotard et al., 2010). This intuitively suggested to us that TBC-4 may be the GAP for RAB-10. Since, attempts to recombinantly express RAB-10 were unsuccessful, we used a Y2H approach to determine the substrate specificity

of TBC-4. Interestingly, TBC-4 bound to RAB-10 at its TBC domain suggesting that RAB-10 is indeed the GAP for RAB-10. Interestingly, TBC-4 also interacted with RAB-8 and RAB-11.1 at sites away from its TBC domain. Since depletion of *rab-8* and *rab-11.1* showed no DCV secretion defect, the meaning of these interactions is unclear. It could be that TBC-4 is recruited by RAB-8 and RAB-11.1 to regulate other trafficking pathways.

A major question in this study was to determine how RAB-5 and RAB-10 cooperate together in regulating DCV secretion? In order to answer this question and identify a link between RAB-5 and RAB-10, we screened known RAB-5 effectors for interaction with RAB-10 and its effectors. RABN-5, a RAB-5 effector, was found to bind to TBC-4 at CC domains distinct from the TBC domain. Interestingly knockdown of RABN-5 phenocopied the DCV defect of *rab-5* and *rab-10* mutants confirming its involvement in this pathway. Mammalian rabaptin-5 has been shown to form a complex with Rab5 and Rabex-5, and acts as stimulator of the GEF activity of Rabex-5 on Rab5. This in turn leads to a polymerization of Rab5 in the early endocytic pathway (Stenmark et al., 1995; Lippe et al., 2001). From the phenotype of *rabn-5* mutants it was not clear if the effect of RAB-5 and RABN-5 on DCV release was an indirect consequence of a perturbed endocytic pathway. To distinguish these two functions, we tested another molecule necessary for homotypic fusion during endocytosis, EEA-1 (Simonsen et al., 1998). Interestingly, knockdown of EEA-1 did not result in decreased DCV secretion. This suggests that RABN-5 has a specific secondary function in regulating DCV exocytosis by recruiting TBC-4 for the local inactivation of RAB-10.

## 9.2 A RAB-5 / RAB-10 exclusion cascade

It has been shown that, inside the cell, multiple Rab GTPases can work together in a cascade to provide directionality during compartment maturation. Two distinct types of cascades have been identified: Rab conversions and Rab exclusions. In a Rab conversion, a specific Rab recruits the GEF of a secondary Rab allowing for a compartment to sequentially acquire a new Rab label. The best example of such a cascade is seen between Rab5 and Rab7. Early endosome localized Rab5 molecules recruit the HOPS complex, which possesses GEF activity for Rab7, leading to maturation of Rab5 positive compartments to a Rab7 positive compartments (Rink et al., 2005). In contrast, during Rab exclusion, a specific Rab recruits the GAP of

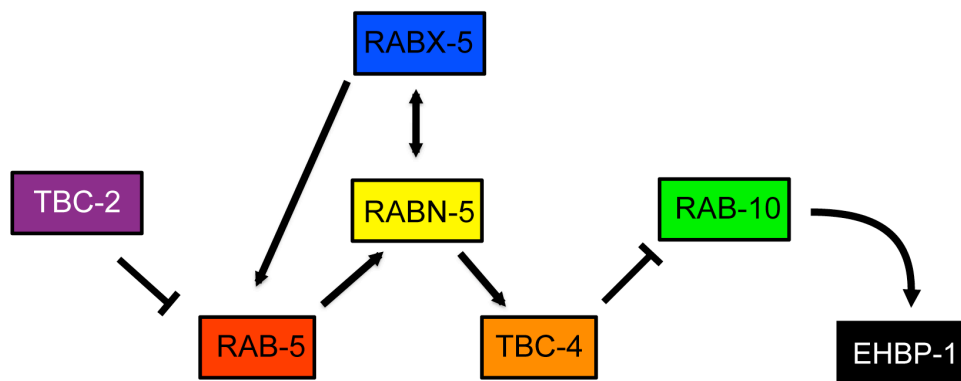

secondary Rab allowing for inactivation of the secondary Rab during compartmental maturation. This is seen between the yeast Rabs, Ypt1 and Ypt31. Ypt31 recruits Gyp1, which is a GAP for Ypt1. This allows for exclusion of Ypt1 from Ypt31 positive membranes during transport through the Golgi (Rivera-Molina and Novick, 2009).

The results of this study provide evidence for the existence of a potential Rab exclusion cascade between RAB-5 and RAB-10 to regulate DCV function. In this cascade, RAB-5 would indirectly recruit TBC-4 through its interaction with RABN-5. The presence of TBC-4 on RAB-5 positive membranes would then locally inactivate RAB-10 excluding it from a RAB-5 domain. Considering that the binding of RAB-10 to EHBP-1 is also essential for DCV release, it is likely that the inactivated RAB-10 would be recruited to an EHBP-1 positive compartment (Fig. IX.1). The finding that, EHBP-1, unlike classical Rab-Effectors, is autonomously targeted to membranes, would support this (Shi et al., 2010). An interesting result was that RAB-10 did not interact with the full length of EHBP-1, but only to the isolated CC domain. An explanation could be that the CC binding site for RAB-10 is kept inaccessible until the end of the RAB-5 / RAB-10 cascade. Additional studies need to be done to determine how the full length EHBP-1 interaction with RAB-10 is modulated. RAB-8 also interacted with the CC domain of EHBP-1, but the function of this interaction is unclear since *rab-8* mutants displayed no defect in DCV secretion. It is possible that RAB-8 still contributes a mild role, which can be compensated by RAB-10, but not *vice versa*. The fact that both genes are synthetically lethal and that *rab-8* mutants generally display milder phenotypes would support this (Chapter 1).

The necessity for DCVs to mature through a RAB-5 / RAB-10 cascade may explain why disruption of any one component leads to a defect in DCV secretion. Multiple studies have suggested that constitutively active Rabs display phenotypes, which are distinctly different from constitutively inactive Rabs (Stenmark et al., 1994; Ullrich et al., 1996; Junutula et al., 2004). This was not the case in our study, as we observed similar phenotypes between dominant mutants of RABs and depletion (by deletion or RNAi) of the same RABs. This suggests that certain complex processes such as DCV maturation and secretion require many molecules to ensure fidelity. In such a process, there is a demand for fully functional Rab cycles, which would be equally disrupted by a constitutively inactive or active Rab. Instances where a constitutively inactive or active Rab displays similar phenotypes have been previously

A

B

**Figure IX.1. Model of a RAB-5 / RAB-10 exclusion cascade.** **A.** The results of this study suggest the existence of a RAB exclusion cascade, which regulates DCV function. In this cascade RAB-5 recruitment to a compartment simultaneously leads to the recruitment of RABN-5. The presence of RABN-5 stimulates the GEF activity of RABX-5 towards RAB-5 (Lippe et al., 2001) and at the same time locally inactivates RAB-10. The inactivated RAB-10 would then re-localize to a neighboring microdomain containing EHBP-1. All molecules would need to work in concert for the formation of fusion competent DCVs. **B.** A schematic representation of how all molecules would work in concert. TBC-2 is not depicted as it is a negative regulator of this pathway and it is likely that it is necessary to switch off this entire process.

reported. Expression of constitutively active or inactive mutants of Rab27 in neurons displayed defects in recycling of SVs (Pavlos et al., 2010). Expression of constitutively active or inactive Rab6 in HeLa cells displayed decreased hemagglutinin transport to the cell surface (Martinez et al., 1994).

### 9.3 Localization of the RAB-5/RAB-10 cascade: cell body or synapse?

Considering that RAB-5 and RAB-10 localize to discrete compartments in neuronal cell somas as well as to synapses (Brown et al., 2009; this study), a major question, which remains to be answered is, where does the RAB-5 / RAB-10 exclusion cascade occur? Given the current set of data, it is difficult to discriminate between the neuronal cell soma and the synapse. If it were to take place in the cell soma, then this cascade would likely occur in synchrony with the maturation process of iDCVs to mDCVs. In this scenario, disruption of the RAB-5 / RAB-10 cascade would lead to missorting of essential factors necessary for mDCV formation. Three such factors are: Syntaxin 6, VAMP4 and Synaptotagmin-IV. All three of these proteins are found on iDCVs and not on mDCVs in neuroendocrine PC12 cells (Tooze et al., 2001). Syntaxin 6 has been shown to be necessary for the homotypic fusion events preceding mDCV formation and is subsequently sorted to the endolysosomal system (Wendler et al., 2001). Synaptotagmin-IV has been shown to bind to syntaxin 6 to regulate homotypic fusion events (Ahras et al., 2006). Interestingly, recent studies in neurons has shown that certain amounts of synaptotagmin IV are also found on mDCVs and that it acts as an inhibitor of DCV release (Dean et al., 2009; Zhang et al., 2009). These results suggest the modulation of synaptotagmin-IV levels have consequences on DCV secretion. It will be interesting to determine the localization of syntaxin 6 and synaptotagmin IV in *rab-5* and *rab-10* mutants. It is possible that these factors are missorted onto mDCVs. It will also be interesting to conduct a proteomic analysis of DCV content in *rab-5* and *rab-10* mutants to identify additional factors that may be missorted in these mutants.

In the second scenario, it is possible that the RAB-5 / RAB-10 cascade occurs at the synapse, perhaps on DCVs. A recent finding that mammalian Rab5 and Rab10 are found on purified DCVs from rat spinal cord neurons, would support this (Zhao et al., 2011). It is unlikely that these RABs are involved in DCV transport since the DCVs are able to reach the synapse in these *rab-5* and *rab-10* mutants. One possibility is that, once at the synapse, DCVs must form specific microdomains prior to fusion. A functional RAB-5/ RAB-10 cascade would lead to the formation of specific RAB-5 and RAB-10 microdomains. In the absence of these microdomains the DCVs may be rendered fusion incompetent. This raises the question: what is the purpose of these microdomains. A simple suggestion would be that they are necessary for efficient tethering of DCVs, prior to fusion. Previous studies have implicated

Rab10 in the insulin-triggered translocation of glucose transporter 4 (GLUT4) vesicles (GSVs) to the plasma membrane in adipocytes. Depletion of Rab10 leads to a drastic decrease in exocytosis of GSVs suggesting a role of this Rab in fusion (Sano et al., 2007; Sano et al., 2008). An appealing idea would be that the role of Rab10 in GSV fusion is analogous to its role in DCV fusion in *C. elegans*. Interestingly, in line with this, additional studies have implicated EHBP-1 and TBC1D4 (a mammalian Rab10 GAP) in GLUT4 translocation (Guilherme et al., 2004; Minea et al., 2005). To date, a role of Rab-5 has not been established, nor a formal RAB-5 / RAB-10 exclusion cascade described in GSV exocytosis. Additional work needs to be conducted to elucidate the potential role of these molecules to verify if the GLUT4 translocation pathway is similar to that of DCV release.

Alternatively, the requirement of the RAB-5 / RAB-10 exclusion cascade at the synapse may involve a role of the actin cytoskeleton. Presynaptic axon terminals have been shown to contain large amounts of filamentous actin (Fifkova and Dilay, 1982; Landis et al., 1988). SVs of the reserve pool were shown to be linked to the actin cytoskeleton through proteins called synapsins (Hilfiker et al., 1999). Synapsins were shown to act as negative regulators of high frequency induced SV exocytosis (Pieribone et al., 1995; Li et al., 1995). Interestingly, it has also been shown recently that synapsins act as negative regulators of DCV release in chromaffin cells (Villanueva et al., 2006). Parallel studies in chromaffin cells have also revealed that actin remodeling contributes significantly to the release of cargoes from DCVs (Felmy, 2007) and that the interaction between an actin motor protein, myosin-Va, and syntaxin-1 plays a role in DCV release (Watanabe et al., 2005). These studies suggest that DCVs are anchored on actin filaments and that exocytosis of DCVs is modulated by actin rearrangements at the synapse. Interestingly EHBP-1 contains a calponin homology (CH) domain. Since, CH domains bind to actin filaments (Korenbaum and Rivero, 2002), it is possible that the interaction of RAB-10 with EHBP-1 is necessary for a remodeling of the synaptic actin cytoskeleton. Such remodeling could be necessary to enable DCV mobility prior to fusion. In this case, the disruption of the RAB-5 / RAB-10 exclusion cascade would trap the DCVs at the synapses preventing them from fusing. Additional studies on the effect of EHBP-1 on synaptic actin dynamics would help to elucidate its role in DCV release.

In summary, we have identified through a systematic analysis of all RABs that RAB-5 and RAB-10 are novel regulators of DCV secretion in *C. elegans*. We have proposed that these molecules work together through a RAB exclusion cascade where active RAB-5 inactivates RAB-10 through recruiting TBC-4. This cascade is thought to occur in the neuronal cell soma or at the synapse. Furthermore, it was shown that disruption of the cascade perturbs DCV release. It is likely that this defect occurs either due to missorting of essential factors for fusion, failure to form the appropriate Rab microdomains necessary for tethering, or due to incorrect actin remodeling necessary for fusion.

## X. MATERIALS AND METHODS

### 10.1 Molecular Cloning

Molecular cloning was conducted using classical recombinant molecular biology techniques (Sambrook and Russel, 2001). All bacterial strains and constructs used for cloning are listed in the Appendix. Each construct is described with the primers used for PCR and restriction sites used for cloning. DNA sequences of all primers (Invitrogen) can also be found in the Appendix. All genes of interest were PCR amplified out of a *C. elegans* cDNA library (Proquest). All genomic loci of interest were PCR amplified out of purified *C. elegans* genomic DNA (provided by Christina Pelzelt). *PfuUltra* II Polymerase (Stratagene) was used for all cloning PCR reactions. For genotyping PCR reactions *Taq* Polymerase (Invitrogen) was used. A standard 25  $\mu$ l PCR mix contained 1  $\mu$ l of each primer [10 $\mu$ M], 2.5  $\mu$ l 10x PCR buffer (Stratagene/Invitrogen), 0.5 $\mu$ l dNTP's [10mM], 0.5 $\mu$ l of Polymerase, 20-200 ng DNA template and the remaining volume was filled with double distilled H<sub>2</sub>O (ddH<sub>2</sub>O).

Restriction enzymes, T4 DNA ligase and respective buffers were purchased from Fermentas and New England Biolabs. Restriction digest was typically conducted in a reaction volume of 20  $\mu$ l, with 2  $\mu$ l of 10x digestion buffer, 0.5  $\mu$ l of each restriction enzyme, 1  $\mu$ g of DNA, and remaining volume filled with ddH<sub>2</sub>O. Reactions were carried out for 2-3 hours at 37 °C. Ligation reactions were conducted in a reaction volume of 20  $\mu$ l, with 2  $\mu$ l of 10x ligation buffer, 1  $\mu$ l of ligase, 25 ng DNA (total mass of vector and insert), and remaining volume filled with ddH<sub>2</sub>O. Ligation reactions were carried out overnight at 15 °C. A subset of constructs was cloned using the Invitrogen Gateway cloning system. LR reaction mixes consisted of a total volume of 20  $\mu$ l with 100 ng of the entry clone, 100 ng of destination vector, 2  $\mu$ l of LR clonase, 8  $\mu$ l of TE buffer (Appendix) and the remaining volume filled with

ddH<sub>2</sub>O. LR reaction mix was incubated at 25 °C for 1 hour. After reaction, 1 µl of proteinase K was added and incubated at 37 °C for 10 minutes to terminate the LR reaction. All PCR reactions and digestion products were analyzed on 1% agarose gels (Invitrogen), run on 1x TBE buffer (Appendix).

All ligation mixes were transformed into 100 µl chemi-competent DH5α cells (Invitrogen) through the heat-shock transformation method. After mixing of ligation products with DH5α cells, the mixture was allowed to stand for 25 minutes on ice. Then mixture was heat shocked for 2 minutes at 42°C and placed back on ice for 2 minutes. For recovery, 900 µl of LB medium (Appendix) was added and then placed on a shaker at 37 °C for 45 minutes. After recovery, cells were pelleted, resuspended and plated on to ampicillin or kanamycin containing LB-agar plates (Appendix). Following transformation, colonies were picked and inoculated with desired volume of LB media. Plasmid DNA was isolated using miniprep kits (Invitrogen) or midiprep kits (JetStar). For transformation of LR reaction products, DB3.1 cells were used.

## 10.2 *C. elegans* genetics

### 10.2.1 Strains

All strains were cultured at 20° C on OP50 *E.coli*-seeded Nematode Growth Medium (NGM) plates as previously (Brenner, 1974). All mutant *C. elegans* strains used in this study were ordered from the *C. elegans* Gene Knockout Consortium (CGC-Vancouver, Canada and Minnesota/Oklahoma, USA) and/or the National Bioresource Project for the Nematode *C. elegans* (Tokyo, Japan). Strains used in this study are listed in the Appendix.

### 10.2.2 Crosses

Males for crosses were induced via heatshock. 6 large NGM plates (100mm), each containing 20 L4 N2 worms was prepared. Plates were kept at 30° C for heatshock. 2 plates were removed at 5 hours, 2 plates were removed at 5.5 hours, and 2 plates were removed at 6 hours and kept at 20° C. The F1 progeny were screened for males. Usually, < 5 % of the population is positive. Males were then isolated and used to cross an allele of interest into a desired genetic background. After crossing,

homozygous F2 progeny were selected through phenotypic selection or by worm PCR.

For worm PCR, animals needed to be first lysed. For worm lysis, few animals from a strain of interest were suspended in lysis buffer containing proteinase K (Appendix). Worms were first placed at  $-80^{\circ}\text{C}$  for 20 min to allow ice crystals to initially rupture tissue. Subsequently worms were transferred to  $65^{\circ}\text{C}$  for 1 hour to allow proteinase K to digest the worm extract. After lysis, proteinase K was inactivated with a  $95^{\circ}\text{C}$  step for 20 min. 2  $\mu\text{l}$  of lysate was used as template for the worm PCR reaction. Note that worm PCR is carried for the detection of deletion mutant alleles. Primers are designed to bind outside a deletion locus and also inside the locus to confirm homozygosity. Lists of all deletion alleles that were used in this study along with the sizes of the deletions and the primers used to screen for the deletion can be found in the Appendix. The DNA sequences of the screening primers can also be found in the Appendix.

### 10.2.3 Generation of transgenic lines

Transgenic lines carrying extrachromosomal arrays were generated through microinjection as previously described (Mello and Fire, 1995). Injection mixes containing genes of interest, co-injection marker and pBluescript combined in a final concentration of 100 ng/ $\mu\text{l}$  were used for injections. All the injection mixes that were used describing the genes of interest, co-injection markers and respective concentrations used can be found in the Appendix. Usually two independent transgenic lines per injection mix were generated. The transgenic lines generated in this study are also listed in the Appendix, after the mutant strains.

A number of integrated transgenic lines were obtained from the CGC and from other *C. elegans* labs: *nuIs152[punc-129::gfp-snb-1]*, *nuIs168[punc-129::venus-rab-3]*, *nuIs183[punc-129::nlp-21-venus]* and *nuIs195[punc-129::ins-22-venus]* were provided by Joshua Kaplan, (Massachusetts General Hospital, Boston, MA). *ZxIs5[punc-17::chop-2(H134R)-yfp;lin-15(+)] X* and *zxIs6[punc-17::chop-2(H134R)-yfp;lin-15(+)] IV* were provided by Alexander Gottschalk (Johann Wolfgang Goethe-Universität, Frankfurt, Germany). *BIs34[prme-8::rme-8-gfp]* was provided by Barth Grant (Rutgers University, New Jersey, USA).

### **10.3 *C. elegans* behavioral assays**

#### **10.3.1 Movement analysis**

To assay worm movement, the number of body bends per minute was assayed. Individual animals were transferred from seeded NGM plates to non-seeded NGM plates. The number of sinusoidal body bends per minute was visually measured. Each animal was tested for three minutes and at least 10 animals were assayed per strain.

#### **10.3.2 Defecation motor program analysis**

For assaying defecation, two parameters were measured: Success of expulsion events and the cycle length between subsequent posterior body contractions (Thomas, 1990). A minimum of 10 animals per strain were analyzed and each animal was recorded for 5-10 minutes.

#### **10.3.3 Egg-laying analysis**

The egg-laying assay was performed as previously described (Patel et al., 2006.) 20 Young adult worms were transferred to fresh plates and after 30 min, the developmental stage of each newly laid egg was assessed into three distinct stages: one-to-eight-cell stage, nine-cell-to-comma stage and postcomma stage.

#### **10.3.4 Pharmacological assays**

Pharmacological assays for synaptic transmission were conducted with aldicarb as described previously (Mahoney et al. 2006b). Seeded NGM plates containing 2mM aldicarb were prepared (Riedel de Haen). 30 animals per strain were transferred onto aldicarb plates and assessed after 90 minutes of exposure. The percentage of animals paralyzed was quantified. Paralysis was determined by failure to move after prodding with silver wire. Levamisole sensitivity assays were conducted as previously described (Lewis et al., 1980). NGM plates containing 1mM levamisole were prepared (Sigma Aldrich). 30 animals per strain were transferred onto levamisole plates and observed after 80 minutes of exposure. The percentage of animals paralyzed was quantified.

#### 10.4 DiI staining

A stock solution of 2 mg/ml 1,1'-dioctadecyl-3,3',3''-tetramethylindocarbocyanine perchlorate (DiI) (Molecular Probes) in N,N-dimethylformamide was stored at -20°. For the working solution, the stock was diluted 1:200 in M9 buffer (Appendix). Strains were then soaked in the DiI working solution for 2-3 hours at room temperature. After staining, worms were washed 2-3x with M9 buffer and spotted onto NGM plates for destaining. 1 hour later worms were mounted onto 2% agarose pads for imaging (Bacaj et al., 2008).

#### 10.5 Chemosensation assay

This assay was modified from a previously described protocol (Wicks, 2000). A solution of 150 mM CuSO<sub>4</sub> with trace amounts of bromophenol blue was prepared. Bromophenol blue was used to color the solution to allow visibility under the light microscope. A line of copper sulfate solution was drawn across the midline of an unseeded NGM plate. The strain to be assayed was washed twice with S-Basal Buffer to remove bacteria and spotted to one side of the assay plate. 2 µl of an attractant, isoamyl alcohol (diliuted 1:10 in ethanol) was placed on the opposite side of the plate across the line of copper sulfate. Wild type worms approach the attractant, but do not cross the line of copper sulfate. The ability of worms to be attracted to isoamyl alcohol and avoid copper was qualitatively assessed.

#### 10.6 RNAi by feeding

Genes of interest were knocked down by feeding RNAi as previously described (Kamath et al., 2001). All genes for RNAi experiments were cloned into L4440, a vector with two opposing T7 polymerase binding sites flanking the multiple cloning site. The vectors were then transformed into *E.coli* HT115 (DE3) strain. The overnight culture grown in LB media, was seeded onto NGM plates containing 100 µg/ml ampicillin and 1mM isopropyl β-D-thiogalactopyranoside (IPTG). 10 L4 animals of strains of interest in an *eri-1(mg366)* background, were transferred onto plates and allowed to lay eggs for 12 hours. The animals were then transferred to a second round of plates and allowed to lay eggs for another 12 hours. Parents were then removed and the progeny were analyzed/scored for phenotypes. All the RNAi constructs that were cloned can be found in the Appendix. Table III.2 lists all the

strains of interest that were crossed into the *eri-1(mg366)* background. For neuron-specific RNAi, the *eri-1(mg366);rde-4(ne301); gz133 [punc-129::rde-4]* strain was used.

### 10.7 Confocal microscopy and image analysis

Animals were immobilized with 50mM Na-azide and placed on 2% agarose pads. All imaging was performed on an inverted confocal microscope (SP2, Leica). Images were taken using a 63x NA 1.32 / 40x NA 1.25 oil immersion objectives at 20 ° C. Stacks of regions of interest were taken and then compiled to generate maximum intensity projections using Leica software.

For expression pattern analysis segments of worms were separately imaged and a composite image of a full-length worm was generated using Photoshop. For sub-cellular localizations, images of neuronal cell somas from the VNC were taken. Images for quantification from DNC and coelomocytes was carried out as described previously (Sieburth et al., 2005; Sieburth et al., 2007). Maximum stack projections taken from the confocal software were thresholded and quantified using ImageJ software (National Institutes of Health) as described previously (Sumakovic et al., 2009). All data was normalized to wild type, where indicated.

For imaging of the DyI stained worms an inverted Olympus IX81 microscope combined with a PerkinElmer Ultraview Vox spinning disk setup was used. A 40x NA 0.75 air immersion lens was used for imaging. Stacks of regions of interest were taken and then compiled to generate maximum intensity projections using PerkinElmer software.

### 10.8 TR-BSA endocytosis assay

The endocytosis of the fluid-marker (TR-BSA), was monitored as described previously (Zhang et al., 2001). Strains of interest were crossed into the bIs34 strain to label early endosomes. 1mg/ml of TR-BSA was injected into the pseudocoelom near the pharynx of adult animals. After specific time points 10 mins, 30 mins, and 45 mins, animals were transferred onto chilled NGM plates to retard trafficking and prepared subsequently for imaging. At least 4 different animals were injected and imaged for each time point.

### 10.9 High-pressure freeze electron microscopy

A 100 µm deep aluminium platelet (Microscopy Services, Flintbek) was filled with E.coli OP 50 suspension. About 20 young adult worms were transferred into the chamber and immediately frozen using a BalTec HPM 10. Freeze substitution was carried out in a Leica AFS2. Incubations were at -90 °C for 100 h in 0,1 % tannic acid, 7 h in 2 % OsO<sub>4</sub>, and at -20 °C for 16 h in 2 % OsO<sub>4</sub>, followed by embedding in EPON at RT (Rostaing et al., 2004) (all solutions w/v in dry acetone). 50 nm sections were mounted on copper slot grids and placed for 10 min on drops of 4 % (w/v) uranyl acetate in 75% methanol and then washed in distilled water. After air drying the grids were placed on lead citrate (Reynolds, 1963) for 2 min in a CO<sub>2</sub>-free chamber, and rinsed in distilled water. Micrographs were taken with a 1024 × 1024 CCD detector (Proscan CCD HSS 512/1024; Proscan Electronic Systems, Scheuring, Germany) in a Zeiss EM 902A, operated in the bright field mode.

### 10.10 Electrophysiology

Recordings from dissected *C. elegans* body wall muscle cells were conducted as described previously (Liewald et al., 2008). After dissection, cells were treated for 8 s with 0.5 mg/ml collagenase (Sigma-Aldrich, Germany) in modified Ascaris Ringer's (AR; 150 mM NaCl, 5 mM KCl, 5 mM CaCl<sub>2</sub>, 1 mM MgCl<sub>2</sub>, 10 mM glucose, 15 mM HEPES (pH 7.35), 340 mOsm) and washed with AR. Cells were clamped to a holding potential of -60 mV using an EPC10 amplifier and analyzed by Pulse software (HEKA Electronics, Germany). The bath solution was AR, the pipette solution was 120 mM KCl, 20 mM KOH, 4 mM MgCl<sub>2</sub>, 5 mM TRIS-HCl (pH 7.2), 0.25 mM CaCl<sub>2</sub>, 4 mM ATP, 36 mM sucrose, and 5 mM EGTA (315 mOsm). Light activation was performed using a LED lamp (KSL-70, Rapp OptoElectronic, Germany) at a wavelength of 470nm (8mW/mm<sup>2</sup>), and controlled by the HEKA amplifier software.

### 10.11 Yeast-2-hybrid

The Matchmaker yeast two-hybrid assay was performed according to manufacturers protocol (Clontech). All dominant active and dominant negative Rabs were cloned into the bait vector pGBKT7, whereas *tbc-4*, *tbc-4* (377-825), *rabn-5* and *tbc-4* R155A were cloned into the prey vector pGADT7 (Clontech). All yeast-2-hybrid vectors are listed in table III.1. The plasmid combinations of interest were

transformed into the yeast strain AH109 (Clontech) and tested for interaction by spotting on selective plates lacking histidine. Composition of YAPD, transformation and spotting plates can be found in the Appendix.

### **10.12 Protein expression and purification**

All *rab* genes were cloned into the pGST (Glutathione-S-transferase) parallel II vector (Sheffield et al., 1999). Vectors were transformed into the *E. coli* BL21 star (DE3) strain (Invitrogen). Protein expression was induced with 0.1-1mM IPTG at an OD range of 0.4-0.6. Expression was stopped after 4 hours. Cells were pelleted and resuspended in cleavage buffer (Appendix). The solution was sonicated on ice and centrifuged at 11500g (SS-34 rotor) for 30 minutes to remove cellular debris. The supernatant was incubated with GST-Sepharose beads (GE healthcare) for one hour on room temperature. Then washed 3x with 3mL PBS and eluted with GST elution buffer (Appendix). Purity of protein was then judged by boiling 10 µl of protein sample in SDS and running samples through SDS-PAGE. SDS gels were prepared and run using a BioRad Mini-PROTEAN 3 cell electrophoresis system and 1x SDS running buffer (Appendix). 10% gels were used and run at 160 V for 60-90 minutes. Gels were stained with Coomassie Brilliant Blue R250 and destained with Coomassie destaining buffer (Appendix).

## XII. APPENDIX

### 12.1 Constructs and bacteria/yeast strains

All bacterial/yeast strains and constructs used in this study are listed in table XII.1. A brief description is provided about all the backbone vectors used as well as the cloning strategies used for the generation of new vectors.

**Table XII.1. List of all bacterial/yeast strains and constructs used in study**

<b>Bacteria and Yeast Strains</b>	<b>Description</b>		<b>Source</b>
DH5 $\alpha$	<i>E.coli</i> strain used for general molecular cloning		Invitrogen
DB3.1	<i>E.coli</i> strain used for molecular cloning of vectors containing the <i>ccdB</i> gene. Contains the <i>gyrA462</i> allele, which confers resistance to <i>ccdB</i> . For gateway cloning		Invitrogen
BI21-Star (DE3)	<i>E.coli</i> Strain for protein expression. DE3 indicate that the expression of T7 polymerase is inducible by IPTG. Contains additional mutation in <i>rne131</i> , an RNAase.		Invitrogen
HT115 (DE3)	<i>E.coli</i> Strain for feeding induced RNAi in <i>C.elegans</i> . Double stranded RNA induced by IPTG		Kamath et al., 2001
OP50	<i>E.coil</i> strain for feeding <i>C.elegans</i>		Brenner, 1974
AH109	<i>S.cerevisiae</i> strain used for yeast-2-hybrid		Clontech
<b>Backbone Vectors</b>	<b>Resistance Gene</b>	<b>Description</b>	<b>Source</b>
pBluescript SK (+)	Amp <sup>r</sup>	Entry vector used for cloning	Stratagene
pENTR4	Kan <sup>r</sup>	Gateway entry vector	Invitrogen
pGEMT	Amp <sup>r</sup>	Entry vector for TA cloning	Promega
pPD115.62( <i>pmyo-3::gfp</i> )	Amp <sup>r</sup>	Muscle expression vector for <i>C.elegans</i> Contains <i>unc-54 3'UTR</i>	Andrew Fire vector kit
<i>phsp-16.41::tagRFP</i>	Amp <sup>r</sup>	Heat shock induced expression vector for <i>C.elegans</i> . Based on pPD115.62	Kindly provided by Katrin Schwarze and Sabine Koenig
<i>prab-3::mcherry</i>	Amp <sup>r</sup>	Neuronal expression vector for <i>C.elegans</i> . Based on pPD115.62	Kindly provided by Marija Sumakovic
<i>prab-3::tagRFP</i>	Amp <sup>r</sup>	Neuronal expression vector for <i>C.elegans</i> . Based on pPD115.62	Kindly provided by Marija Sumakovic
<i>prab-3::gfp</i>	Amp <sup>r</sup>	Neuronal expression vector for <i>C.elegans</i> . Based on pPD115.62	Kindly provided by Marija Sumakovic
<i>punc-129::mcherry</i>	Amp <sup>r</sup>	DA and DB motoneuron expression vector for <i>C.elegans</i> . Based on <i>prab-3::mcherry</i>	Kindly provided by Marija Sumakovic
L4440	Amp <sup>r</sup>	Entry vector for feeding RNAi	Kindly provided by Julie Ahringer
pGST parallel 2	Amp <sup>r</sup>	GST-Protein expression vector based on pGEX4T1	Sheffield et al., 1999
pGBKT7	Kan <sup>r</sup>	Yeast-2-hybrid vector containing DNA binding domain	Clontech
pGADT7	Amp <sup>r</sup>	Yeast-2-hybrid vector containing DNA activating domain	Clontech

### 12.3 Injection mixes for extrachromosomal arrays

All injection mixes used to generate transgenic lines bearing extrachromosomal arrays are listed in table XII.3

**Table XII.3. List of all injection mixes used to generate transgenic lines**

Array Name	Plasmids of interest	Markers
gz130	5 ng/μl <i>punc-129::mcherry-rab-10</i>	20 ng/μl <i>prab-28::tagRFP</i>

## 12.4 Deletion alleles

All deletion alleles were genotyped using worm PCR. Table XII.4 lists all the deletion alleles used in this study along with the respective primers used for genotyping. Expected band sizes for wild type (WT) are shown.

**Table XII.4. List of all deletion alleles with respective worm PCR primers used in this study**

Deletion strains used in study	Size of deletion (bp)	Outside deletion primers	PCR band size in WT (bp)	Inside deletion primers	PCR band size in WT (bp)

## 12.5 DNA sequences of primers:

Table XII.5 lists the DNA sequences of all primers that were used in this study. All primers are numbered with an oGQ number, which is an internal reference number specific to the Eimer lab.

**12.6 Media****Luria-Bertani (LB) Medium**

5 g/l	Peptone (Roth)
2.5g/l	Yeast extract (Roth)
5 g/l	NaCl (Roth)
7.5 g/l	Agar (Roth), for plates
100 µg/ml	Ampicillin (Roth)
15 µg/ml	Kanamycin (Roth)

**Nematode Growth Medium (NGM)**

16 g/l	Agar
3 g/l	Peptone
3 g/l	NaCl
25 ml/l	1M KPO <sub>4</sub> Solution (Roth)
1 ml/l	1M MgSO <sub>4</sub> Solution (Roth)
1 ml/l	1M CaCl <sub>2</sub> Solution (Roth)
1ml/l	10 mg/ml Nystatin (Sigma)
1 ml/l	5 mg/ml Cholesterol (Roth)

**Complex (YAPD) yeast media**

10 g/l	Yeast extract
20 g/l	Peptone
20 g/l	Glucose (Roth)
1 g/l	Adenine Sulfate (Roth)
20 g/l	Select agar (Invitrogen)

**Yeast minimal growth medium**

6.8 g/l	Yeast nitrogen base (Invitrogen)
1.0 g/l	16 amino acid mix (-leu. -trp, -his, -ura)
20 g/l	Select agar, for plates
	pH 6-7

After autoclaving:

10 ml/l	amino acid solution (+his 480 mg/200 ml) (+ura 480 mg/200 ml)
40 ml/l	50% Glucose

## 12.7 Buffers and solutions

### Worm lysis/PCR buffer (1x)

100 mM	Tris pH 8.3
500 mM	KCl (Roth)
20 mM	MgCl <sub>2</sub> (Roth)
20 mg/ml	Proteinase K added fresh prior to lysis (Roth)

### Worm lysis/PCR buffer (10x)

1 M	Tris pH 8.3
5 M	KCl
200 mM	MgCl <sub>2</sub>

### TE buffer

10 mM	Tris-HCl pH 8.0
1 mM	EDTA (Roth)

### TBE buffer (10x)

108 g/l	Tris NaOH
55 g/l	Boric acid (Roth)
9.3 g/l	EDTA (pH 8.0)

### M9 buffer

3 g/l	KH <sub>2</sub> PO <sub>4</sub> (Roth)
6 g/l	Na <sub>2</sub> HPO <sub>4</sub> (Roth)
5 g/l	NaCl (Roth)
1 ml	1M MgSO <sub>4</sub> (Roth)

### GST cleavage buffer

50 mM	Tris-HCl pH 7.0 - 7.3 (Roth)
150 mM	NaCl
1 mM	EDTA
2 mM	DTT (Roth)
100 µM	Pefabloc protease inhibitor cocktail (Roche)

### GST elution buffer

50 mM	Tris-HCl pH 8.0
150 mM	NaCl
20 mM	reduced glutathione (Roth)

**PBS buffer (1x)**

8 g/l	NaCl
0.2 g/l	KCl
1.44 g/l	Na <sub>2</sub> HPO <sub>4</sub>
0.24 g/l	KH <sub>2</sub> PO <sub>4</sub>

**Yeast transformation 1-step buffer**

0.2 M	Lithium Acetate (0.4g) (Roth)
40%	PEG 4000 (12-15g) (Sigma)
100 mM	DTT (0.46g)

Fill up to 30 ml with ddH<sub>2</sub>O and filtrate

**10% APS solution**

1 g	APS (Roth)
10 ml	ddH <sub>2</sub> O

**SDS running buffer (10x)**

30.3 g/l	Tris
144 g/l	Glycine (Roth)
10 g/l	SDS (Roth)
	pH 8.3

**2x SDS sample buffer**

121.1 g/l	Tris pH 6.8
20 %	Glycerol (v/v)
100 g/l	SDS
0.002 %	Bromophenol blue (w/v)
200 ml	2-Mercaptoethanol (Sigma Aldrich)

**5% Stacking gel – 5 ml**

0.83 ml	30 % Acrylamide/Bis (Roth)
3.4 ml	ddH <sub>2</sub> O
0.63 ml	1.0 M Tris, pH 6.8
50 µl	10 % SDS
50 µl	10 % APS (Roth)
5 µl	TEMED (Roth)

**10 % Resolving Gel - 15ml**

5 ml	30 % Acrylamide/Bis
5.9 ml	ddH <sub>2</sub> O
3.8 ml	1.5 M Tris, pH 8.8
150 µl	10 % SDS
150 µl	10 % APS
6 µl	TEMED

**Coomassie Blue Stain**

0.25 %	Coomassie Brilliant Blue R250 (BioRad)
50 %	Methanol (Roth)
10 %	Acetic acid (Roth)

**Coomassie destainer**

5 %	Methanol (Roth)
7.5 %	Acetic acid (Roth)

**12.8 Gene structures of *tbc-4* and *rabn-5* deletion alleles**

Since the *tbc-4* and *rabn-5* alleles used in this study were not published before, they are depicted below. Gene structures for all the *rab* mutants used in this study are depicted in Chapter 1: Results (IV).

***tbc-4******rabn-5***

**Figure XII.1. Gene structures of *tbc-4* and *rabn-5*.** Two alleles of *tbc-4*: *tbc-4* (*ok2928*), *tbc-4* (*tm3255*) and one allele of *rabn-5*: *rabn-5* (*ok1555*) were used in this study. The red line depicts the region that is deleted for the corresponding mutant alleles.

## 12.9 Multiple sequence alignment of TBC-4

**Figure XII.2. Multiple sequence alignment of TBC-4.** The protein sequence of TBC-4 is shown aligned together with the closest human orthologues: Evi5 and Evi5-like. TBC-4 contains one TBC domain (shown in purple) and four coiled coil (CC) domains (shown in green). A white triangle depicts the catalytic arginine finger R155. Source: Multiple sequence alignment was done using the MUSCLE tool and the output was generated using BOXSHADE.

# CURRICULUM VITAE

## NIKHIL SASIDHARAN

European Neuroscience Institute  
Grisebachstrasse 5  
37077 Göttingen, Germany  
++49 176 2707 3539  
[nsasidh@gwdg.de](mailto:nsasidh@gwdg.de)

Nationality: Indian  
Date of Birth: 14/10/1985  
Place of Birth: Attingal, India

---

## EDUCATION

10/2007 to date **European Neuroscience Institute, Göttingen, Germany**  
Pursuing PhD degree in Neurosciences, expected to finish in April 2011

09/2006 – 09/2007 **Max Planck Research School, Göttingen, Germany**  
Completed preparatory year of coursework in Neurosciences prior to entering PhD  
Earned final grade A in M.Sc Examination

08/2003 – 06/2006 **Jacobs University Bremen, Bremen, Germany**  
Earned a B.Sc. degree in Biochemistry and Cell Biology  
Graduated in the top 5% of class

08/1999 – 05/2003 **Kodaikanal International School, Kodaikanal, India**  
Successfully completed high school education  
Earned International Baccalaureate diploma in Mathematics, Physics and Chemistry

---

## PRACTICAL EXPERIENCE

10/2007 to date **European Neuroscience Institute, Göttingen, Germany**  
PhD project in the laboratory of Dr. Stefan Eimer  
Studying the role of Rab GTPases in neuronal membrane trafficking in *C.elegans*  
Methods: Spinning-disk microscopy, transgenesis, assaying worm behaviors, molecular cloning, protein expression and purification, *in vitro* GTPase assays, high-throughput yeast-2-hybrid screening, high-throughput functional RNAi screening.

03/2007 – 05/2007 **Max Planck Institute for Experimental Medicine, Göttingen, Germany**  
Laboratory Rotation in the neurobiology laboratory of Prof. Dr. Klaus Nave  
Studied the role of Neuregulin1 in CNS myelination of young mice  
Methods: Cre-Lox recombinant techniques, immunohistochemistry

01/2007 – 03/2007 **Institute for Physiology, University of Goettingen, Göttingen, Germany**  
Laboratory Rotation in the neurophysiology laboratory of Dr. Weiqi Zhang  
The effect of erythropoietin (EPO) on Pre-Boetzinger complex in mouse brain-stem  
Methods: Whole-cell patch clamp of brain-stem slices

02/2006 – 06/2006 **Jacobs University Bremen, Bremen, Germany**  
B.Sc thesis project in the biochemistry laboratory of Prof. Dr. Albert Jeltsch  
Studied the molecular enzymology of DNA Methyltransferase I (DNMT 1) *in vivo* using novel imaging assay

10/2005 – 02/2006  
Methods: Molecular cloning, Realtime PCR, Western Blotting, Fluorescence microscopy  
**Jacobs University Bremen, Bremen, Germany**  
Teaching Assistant for the "Advanced Biochemistry and Cell Biology I Lab Course"  
Supervision of experiments, assistance in tutorials and grading of quizzes  
Methods: SDS-PAGE, Agarose Gel Electrophoresis, Western Blotting, PCR

---

### EXTRACURRICULAR ACTIVITIES

07/2009 - 08/2009 **Roche Continents, Salzburg, Austria**  
Youth, Arts and Science program  
Participated in workshops for team-building and creativity in arts and science

09/2008 - 05/2009 **Max Planck Institute for Experimental Medicine, Göttingen, Germany**  
Organizing member of the Neurizons 2009, conference in the Neurosciences  
Involved in general organization, website and booklet (<http://www.neurizons.uni-goettingen.de/>)

03/2007 – 04/2007 **Max Planck Institute for Experimental Medicine, Göttingen, Germany**  
Indian Culture Night  
Organizer of cultural events about India

06/2006 – 07/2006 **Berlitz AG, Berlin, Germany**  
Kids and Teens - English Camp  
English teacher for kids age group 8-12

09/2001 – 05/2003 **Kodaikanal International School, Kodaikanal, India**  
Social aid project  
Participated in providing aid and assisted in building infrastructures for target village  
Malayandipuram, India

---

### SKILLS & INTERESTS

**Languages** English: Fluent in written and spoken German: Working knowledge  
French: Advanced in written and spoken Malayalam: Mother tongue

**PC Knowledge** Microsoft Office, Adobe illustrator and photoshop, ImageJ  
**Programming** HTML, and basic knowledge of pascal  
**Merits/Awards** GGNB excellence fellowship for PhD studies, Göttingen, Germany  
Max Planck excellence stipend for PhD studies, Göttingen, Germany  
Merit-based scholarship for undergraduate studies at the Jacobs University Bremen, Germany

**Hobbies** Learning to play guitar, hiking, squash and reading books of biology and history

## LIST OF PUBLICATIONS

Luo L., Hannemann M., Koenig S., Hegermann J., Ailion M., Cho M.-K., **Sasidharan N.**, Zweckstetter M., Rensing S.A. and Eimer S. The *C. elegans* GARP complex contains the conserved Vps51 subunit and is required to maintain lysosomal morphology. In revision at MBoC.

Butkevich E., Hegermann J., **Sasidharan N.**, Lecaudey V., Eimer S.\* and Klopfenstein D.R.\*. The Kinesin-1 is required for dendritic cargo transport and microtubule integrity in *Caenorhabditis elegans* neurons. \* Corresponding authors. In revision at J. Neurosci.
