

**Interaction of hepatic uptake transporters with
antineoplastic compounds and regulation of the
expression of organic cation transporter 3 in renal
carcinoma cells**

Doctoral Thesis

In partial fulfillment of the requirements for the degree

“Doctor rerum naturalium (Dr. rer. nat.)”

in the Molecular Medicine Study Program

at the Georg-August University Göttingen

submitted by

Venkata V. V. R. Marada

born in Visakhapatnam, India

Göttingen 2014

Members of the Thesis Committee:

Supervisor:

Prof. Dr. med. Gerhard Burckhardt

Institut für Vegetative Physiologie und Pathophysiologie

Universitätsmedizin Göttingen, Georg-August-Universität

Second member of the thesis committee

Prof. Dr. med. Jürgen Brockmöller

Abteilung Klinische Pharmakologie

Universitätsmedizin Göttingen, Georg-August-Universität

Third member of the thesis committee

Prof. Dr. med. Heidi Hahn

Institut für Humangenetik

Universitätsmedizin Göttingen, Georg-August-Universität

Date of Disputation:

AFFIDAVIT

I hereby declare that my doctoral thesis entitled “Interaction of hepatic uptake transporters with antineoplastic compounds and regulation of the expression of organic cation transporter 3 in renal carcinoma cells” has been written independently with no other sources and aids than quoted.

Acknowledgements

I would like to express my deepest sense of gratitude for Prof. Yohannes Hagos for giving me an opportunity to do PhD in his research group. The years of working here have been a great learning experience in many directions. I thank him for his patience in guiding me in this project and for his help and suggestions to overcome the hurdles I faced in the course of my research.

I am very thankful to Prof. Gerhard Burckhardt for his suggestions and guidance during the course of the project, for making sure that everything is done smoothly and timely, and for his constant support and encouragement for the experiments as well as for the formalities of the PhD program.

My gratitude goes to Prof. Jürgen Brockmüller and Prof. Heidi Hahn for being my thesis committee members. Their suggestions during the thesis committee meetings have been very insightful and expanded the scope of the project to its present shape.

I am thankful to the Graduate College Cancer Pharmacogenomics (GRK 1034) and Prof. Gerhard Burckhardt for the financial support.

It has been a great experience working with Dr. Mladen Tzvetkov and I thank him and his entire group, especially my colleague Sayed Mohammad Hasheminasab for his help with Ion Torrent Sequencing. I also thank our collaborator Dr. Gabriela Salinas-Riester and the staff of DNA deep sequencing and microarray facility in the university, especially Mr. Fabian Ludewig for the generation of microRNA expression data.

I thank Mr. Sören Petzke for his skilful assistance during this period. I learned a lot working with him, and his tips have been very productive for my experiments. I thank Dr. Saskia Flörl and Dr. Annett Kühne of PortaCellTec biosciences for providing me stably

transfected cells. I also want to thank all my past and present colleagues in the department for their help and support with the experiments. I thank Mr. Sina Tadjerpišeh and Dr. Kotini for introducing me to the basics of HPLC and Ms. Judith Müller for helping me work with it. I thank Dr. Pantakani for help with transfections.

I thoroughly enjoyed and learned a lot from the various scientific presentations and I am thankful to Prof. Birgitta C. Burckhardt for organising Göttinger transporttage annually in the department and giving me an opportunity to present my data in it. I also thank Mr. Sven Müller and Dr. Erik Meskauskas for organising yearly retreats and coordinating the academic activities, and all my colleagues in GRK 1034 and the PhD program Molecular Medicine.

Finally, I want to thank all my friends and my family for their understanding, support, and encouragement.

Abstract

The ability of a compound to exert its antineoplastic activity is determined by the amount of its accumulation inside the cell, a process largely dependent on the transporter proteins which are responsible for the passage of compounds into and out of the cell. The present study is focussed on the uptake transporter proteins; their interactions with antineoplastic compounds routinely used in cancer chemotherapy, and the regulation of expression of one such uptake transporter protein, organic cation transporter 3 (OCT3). The interactions of four such uptake transporters, that are predominantly expressed in liver namely, organic anion transporter 2 (OAT2), sodium taurocholate cotransporting polypeptide (NTCP), organic anion transporting polypeptides 1B1 and 1B3 (OATP1B1 and OATP1B3), were analysed in stably transfected human embryonic kidney cells. The transporter proteins were functionally characterized using [³H] model substrates and the uptake of this model substrate was followed in the presence of 100 μM of the antineoplastic compounds. The antineoplastic compounds which were able to inhibit the uptake of model substrate by 60% of buffer control were chosen for further analysis of interaction. No compound could inhibit the NTCP mediated estrone-3-sulfate uptake by 60% of buffer control. The affinity (K_i value) of the transporter proteins for the compounds that inhibited the uptake of model substrate by 60% of buffer control was determined by Dixon-plot analysis. OAT2 was found to strongly interact with bendamustine, irinotecan and paclitaxel with K_i values of 43.3 μM, 26.4 μM, and 10.4 μM, respectively. OATP1B1 interacted with vinblastine and paclitaxel, with K_i values of 10.2 μM and 0.84 μM, respectively. OATP1B3 interacted with chlorambucil, mitoxantrone, vinblastine, vincristine, paclitaxel, and etoposide with K_i values of 37.4 μM, 3.1 μM, 18.6 μM, 17.6 μM, 1.8 μM, and 13.5 μM, respectively.

From the IC_{50} values generated, the possibility of these interactions to contribute to potential drug-drug interactions was calculated. Furthermore, as mentioned above, the regulation of expression of OCT3 in four renal carcinoma cells (A498, ACHN, 786-O, and LN78) with variable OCT3 expression, was analysed at the epigenetic and post-transcriptional levels. Using inhibitors for the processes of histone deacetylation and DNA methylation, the contribution of these processes was validated. It was found that they do not account for the huge difference of expression of OCT3 found between A498 and ACHN cells. In addition, the methylation status of the promoter region of OCT3 was analysed by Ion Torrent sequencing. There was no considerable difference between the methylation status of the promoter regions tested in the four renal carcinoma cell lines. The post-transcriptional regulation of OCT3 by microRNAs was also analysed. MicroRNAs that have the ability to bind to 3' untranslated region of OCT3 were obtained from in silico prediction programs and the expression of these microRNAs was analysed by qRT-PCR. Two microRNAs, hsa-mir-204 and hsa-mir-143, were selected as they showed differential expression in A498 and ACHN cells. The levels of these microRNAs were altered in these cells using small molecules called microRNA mimics and antimirs, and the expression of OCT3 was followed. However, no correlation was observed between the expression levels of these microRNAs and OCT3. In this direction, the search for potential OCT3 regulators was pursued by the next generation sequencing of genome wide microRNA analysis. From the results it is clear that a many microRNAs are differentially expressed in the four renal carcinoma cells. To make more advances in the search for microRNAs which are directly or indirectly involved in the regulation of OCT3, transcriptome analysis from the same RNA samples is being performed. This approach is best suited to dissect any factors involved in the transcriptional as well as post-transcriptional regulation of OCT3.

1. Introduction

1.1. Cancer chemotherapy

Cancer is of utmost health concerns and is one of the primary causes of deaths to humanity worldwide. This made cancer a hot topic of research and the scope of research has widened from therapy to the basic mechanisms of generation of cancer cells, including factors in cells which provide predisposition or risk of cancer and those which are responsible for suppressing the growth of such cells *in vivo*. However, with the complex ecosystem of today's world, the balance seems to have shifted towards factors causing the disease. Though the disease is characterized by a lot of pathways which seem to be commonly involved, it also has a diversity of mechanisms operating in parallel. This fact makes it hard to find a common treatment without understanding the origin of disease in detail. The discrepancies are found not only in origins but also in those processes which are crucial for treatment. Cancer therapy includes methods like radiotherapy, chemotherapy and surgery. However, any of the above methods individually, or in combination, have not been largely successful so far to yield a complete recovery and, at the most increase, the life span of the patients for varying periods of time, depending upon the organ affected. Cancer chemotherapy has the advantage among the treatment options that the side effects of such a therapy would not, in most cases, last long. Compounds which are used in the treatment of cancer are referred to as antineoplastic compounds. Antineoplastic compounds have varying mechanisms of action, while some cause abnormalities in the DNA metabolism; others cause abnormalities in cytoskeletal processes and so on. The ability of an antineoplastic drug to exert its cytostatic effect depends largely on the balance between its uptake into and extrusion from the cancer cells. The uptake transport proteins are involved in the transport of the compounds into

the cells, without the involvement of a direct energy coupling, whereas the efflux transporters drive the compound out the cells coupled with the hydrolysis of ATP.

1.2. Transport proteins

The proteins involved in the transport of antineoplastic compounds are expressed on the surface of cells. The efflux transport proteins are grouped into the ABC (ATP binding cassette) superfamily of proteins which, by virtue of their ability to hydrolyze ATP, drive the molecules out of the cell [1]. They include the proteins P-gp (multidrug resistance protein, MDR1 or ABCB1), breast cancer resistance protein (BCRP) etc. These proteins have been a focal point of extensive research as they are shown to be key determinants of chemoresistance in cells [2;3]. On the other hand, a relatively less studied group of proteins, which also hold key to chemoresistance of a cell are the uptake transport proteins, grouped under the SLC superfamily. They are shown to be involved in the uptake of a number of foreign compounds and influence the initial stages of the absorption, distribution, and metabolism (ADME) of endogens and exogenous compounds.

1.3. Importance of transporter proteins in metabolism of antineoplastic compounds

Most of the antineoplastic compounds in the circulation exist as a protein bound fraction and a free fraction. The free fraction largely represents the active compound and the ability of the compound to exert its cytostatic effects would largely depend on the local concentration of its free fraction achieved in the tumor cells. This process underlines the importance of transporter proteins as they form a determining factor of this process, infact, the efficacy of an antineoplastic compound is determined by the uptake

transporters and efflux transporters as mentioned above [4;5]. Furthermore, abnormalities in the expression of many of the transporter proteins have been associated with discrepancies with the metabolism of an antineoplastic compound and effectiveness of a drug in chemotherapy.

1.4. Uptake transporter proteins

The uptake transporter proteins belong to a vast superfamily of proteins referred to as the SLC (solute carrier) superfamily which is further classified into 53 families, containing almost 400 genes [4]. The classification of this superfamily is based on the sequence similarity of the transporter proteins. The physiological role of these proteins is unrelated to their ability to transport exogenous molecules, suggesting that there is no specific family which is exclusively involved in the uptake of foreign substances. This issue is the basis for an increasing number of studies aimed at finding out which transporter is involved in the transport of which foreign compound [6-8]. It is noteworthy to mention here that any interaction with a foreign compound might potentially cause an alteration in the physiological function of that particular transporter protein and homeostasis of the physiologically relevant endogenous substrates.

1.5. Liver specific uptake transporter proteins

The uptake transport proteins expressed in the liver play a pivotal role in the body as liver is the organ concerned with modification and excretion of endogenous as well as exogenous substances including drugs and their metabolites. Hepatic excretion of drugs invariably involves their uptake transporter mediated absorption from the sinusoidal blood into the hepatocytes wherein they are metabolized and converted to a nontoxic or conjugated form which is excreted. The uptake transport proteins expressed in the liver

include organic cation transporter 1 (OCT1), organic anion transporter 2 (OAT2), OAT7, sodium taurocholate cotransporting polypeptide (NTCP), organic anion transporting polypeptide 1B1 (OATP1B1), OATP1B3, and OATP2B1. The current work deals with the investigation of the ability of four of these proteins, OAT2, NTCP, OATP1B1, and OATP1B3, to interact with some antineoplastic compounds routinely being used in cancer chemotherapy.

1.5.1 Organic anion transporter 2

The organic anion transporter 2 (OAT2), encoded by the gene SLC22A7, is involved in the transport of various organic substances of both endogenous and exogenous origin. It has been shown to be expressed predominantly in liver, and to a lesser extent in kidney, lung and various other tissues in humans [9;10]. Its substrates include many endogenous substances like cGMP, estrone-3-sulfate, dehydroepiandrosterone sulfate, prostaglandin E2, purine analogs, glutamate, orotic acid, uric acid, and exogenous substrates including tetracycline, antiviral compounds like acyclovir, ganciclovir, zidovudine, and paclitaxel among others [11-15]. Two splice variants have been reported for this transporter which differed by 6 ntds, the shorter variant was found to be functional demonstrated by its ability to transport cGMP [11]. The functional splice variant was used in this study.

1.5.2 Sodium taurocholate cotransporting polypeptide

The sodium taurocholate cotransporting polypeptide (NTCP) encoded by the gene SLC10A1, is exclusively expressed in hepatocytes. NTCP is mainly involved in the sodium dependent uptake of bile acids and thus in the enterohepatic circulation [16]. Other than bile acids, its substrates include thyroid hormones, estrone-3-sulfate and drugs like rosuvastatin, pitavastatin [17-19]. A recent report implicated NTCP as the receptor

for Hepatitis B and Hepatitis D viruses, undermining its clinical importance, and hence an inhibitor of NTCP is of high clinical relevance [20].

1.5.3 Organic anion transporting polypeptides 1B1 and 1B3

The organic anion transporting polypeptide 1B1 and 1B3 are encoded by the genes SLCO1B1 and SLCO1B3 genes, respectively. They are involved in the transport of a variety of substances, most of which are amphipathic high molecular weight compounds, and the list includes endogenous substances like bile salts, both conjugated as well as unconjugated bilirubin, leukotrienes, prostaglandins, thyroid hormones and exogenous compounds like statins and certain drugs [21]. Members of OATP1 family were shown to interact with a variety of compounds, and some of these compounds have been proven to be substrates of these proteins. Both these proteins are specifically expressed in the sinusoidal membranes of liver [22;23] and are involved in the hepatic uptake of bile salts, bile pigments, and also a variety of exogenous substances like rosuvastatin, pitavastatin, and hence, play a crucial role in xenobiotic metabolism and regulation of the cholesterol homeostasis.

1.6. Interactions of transporter proteins with antineoplastic compounds

There are various observations citing the involvement of abnormalities in the expression of transporters in the ineffectiveness of substrate uptake [24;25]. This makes it very important to know which transporter proteins are involved in the uptake and efflux of an antineoplastic compound. In literature, there are a lot of studies that focus on the interaction of antineoplastic compounds with transporter proteins. All these studies have a common objective of providing individual therapy which is a prerequisite in the treatment of a disease as complex as cancer.

1.7. Antineoplastic compounds used in the study and their mechanisms of action

In our study we tested several antineoplastic drugs that are routinely used in the treatment of cancer including alkylating agents (melphalan, bendamustine, chlorambucil, cyclophosphamide, trofosfamide, ifosfamide, busulfan, treosulfan, and thio TEPA), antimetabolites (methotrexate, cytosinarabioside, gemcitabine, 5 fluorouracil, fluoroadenine, cladribine, and fludarabine), intercalating agents (doxorubicin and mitoxantrone), topoisomerase inhibitors (irinotecan and etoposide), mitotic inhibitors (vinblastine, vincristine, and paclitaxel) and those having hormone receptors as targets (tamoxifen, prednisone, and clodronic acid).

Alkylating agents follow the common principle of addition of alkyl groups onto the guanine nucleotides in DNA. This process leads to errors during replication and consequently the DNA repair pathways are set in to repair the damaged or altered base, and failure to do so leads to cell death by apoptosis. There are differences in the mechanism of action of alkylating agents; some compounds like melphalan, bendamustine, chlorambucil, cyclophosphamide, ifosfamide, and trofosfamide lead to the alkylation of only one guanosine residue whereas the compounds busulfan and treosulfan alkylate two guanosine residues causing interstrand or intrastrand crosslinks leading to the DNA being arrested in a locked form inaccessible for replication, forcing the cells to either repair or apoptosis [26-28]. The nucleoside analogs cause cytotoxicity upon incorporation into DNA, leading to the accumulation of DNA breaks and subsequently apoptosis [29;30]. 5-fluorouracil, on the other hand, inhibits the enzyme thymidylate synthase enzyme resulting in low levels of dTMP and this imbalance causes DNA damage [31]. Topoisomerases are enzymes that are crucial for the separation of DNA

strands during replication and transcription. The antineoplastic compounds, irinotecan and etoposide, inhibit these enzymes causing extensive accumulation of DNA breaks and consequently cell death. Similarly, the intercalating compounds doxorubicin and mitoxantrone also contribute to the inhibition of topoisomerases [32]. The mitotic inhibitors, vinblastine, vincristine, and paclitaxel alter the structural protein tubulin and consequently spindle dynamics, forcing the cells to arrest the cell division, and to undergo apoptosis [33;34]. The mechanisms of the antineoplastic compounds are diverse as described in this section, but this diversity is made use of in the formulation of treatment regimens involving a combination of the compounds to achieve an effective means to treat various types of cancer as listed below. Furthermore, the success of a treatment regimen depends on the functional expression of the corresponding uptake transport proteins.

1.8. Therapeutic uses of antineoplastic compounds used in the study

Many of these compounds are being used either alone or in combination as front line drugs in chemotherapy of various cancers. A summary of the studies that explore the therapeutic potential of these compounds in clinical trials of specific malignancies and relevant literature is provided in Table 1.1.

Compound	Type of cancer	References
Alkylating agents		
Melphalan	multiple myeloma, retinoblastoma	[35;36]
Bendamustine	chronic lymphocytic leukemia, Non-Hodgkin Lymphoma	[37]
Chlorambucil	chronic lymphocytic leukemia	[38;39]
Cyclophosphamide	breast cancer, B-cell lymphoma	[40-43]
Trofosfamide	non-small cell lung cancer	[44]
Ifosfamide	non-small cell lung cancer, anal cancer	[45;46]
Busulfan	leukemia	[47]
Treosulfan	Malignant melanoma, uveal melanoma	[48;49]
thioTEPA	Acute leukemia	[50]
Antimetabolites		
Methotrexate	Bladder cancer, T cell lymphoma, B-cell lymphoma	[43;51;52]
Cytosine arabinoside	Acute myeloid leukemia, B-cell lymphoma, follicular lymphoma	[43;53-55]
Gemcitabine	Pancreatic cancer, renal cell carcinoma	[45;48;49;56;57]
5-Fluorouracil	Pancreatic cancer, colorectal cancer	[58;59]
Fluoroadenine		
Fludarabine	Chronic lymphocytic leukemia	[60]
Cladribine	Hairy cell leukemia	[61;62]
Intercalating agents		
Doxorubicin	breast cancer, bladder cancer, renal cell carcinoma	[41;51;57]
Mitoxantrone	Acute myeloid leukemia	[54]
Mitotic inhibitors		
Vinblastine	Bladder cancer	[51]
Vincristine	Large B-cell lymphoma	[43]
Paclitaxel	Pancreatic cancer	[63]
Topoisomerase inhibitors		
Irinotecan	Pancreatic cancer, colorectal cancer	[58;59]
Etoposide	T cell lymphoma,	[52]
Hormone receptor targeters		
Prednisone	Follicular lymphoma	[55]
Clodronic acid	Malignant bone metastases	[64]
Tamoxifen	breast cancer	[41]

Table 1.1 Antineoplastic compounds and their therapeutic uses.

1.9. Factors effecting impact of transporter proteins on chemotherapy

There are two main factors which cause considerable variability in the effect of transport proteins on chemotherapy. One of the factors is the widely studied phenomenon of drug-drug interactions. It originates in combinatorial chemotherapies wherein the interaction of the first drug with its transporter causes changes in the effectiveness of a second drug, either decreasing or increasing the bioavailability of the second drug and is associated with ineffective drug therapy or drug mediated cytotoxicity, respectively. There have been a lot of incidences of drug-drug interactions mediated by the OATP and OCT transporters [65]. Since drug-drug interactions can lead to drastic effects during chemotherapy, many models have been put forward which would predict the possibility of drug-drug interactions. Some of the models take into account the interactions of the transporter proteins with the compounds *in vitro*, specifically, the affinity of a transporter protein for the compounds in question [66-69]. The other factor is the alteration in the transport of the antineoplastic compound by the transporter protein. This may arise due to abnormalities in the localization of the protein on the membrane or an aberration in the expression of the transporter protein leading to a loss of its function or specificity for the compound. There are a myriad of mechanisms that influence the expression of a gene operating at various levels such as genetic, epigenetic, transcriptional, post-transcriptional and post-translational levels.

1.9.1 Regulation of expression of genes at genetic and epigenetic levels

Since transporter genes are physiologically important and are at the forefront of cancer chemotherapy, a small change in the nucleotide sequence might cause a magnified effect. Such changes were characterized for many genes as single nucleotide polymorphisms (SNPs) which might lead to the incorporation of a different amino acid into the protein. A

lot of such changes have been mentioned for many transport genes, which were associated with altered substrate recognition or transport [25;70;71]. Normally, DNA is closely bound together and wrapped around histone proteins to form structures called nucleosomes. For the expression of genes, the DNA needs to be made accessible to the synthesizing machinery; a process achieved by chemical modifications on histones. The most common modifications of histones are methylation and acetylation brought about by the histone methyl transferases and histone acetyl transferases. Methylation of histones can be of varied extents such as mono, di or tri-methylation, can occur on the same lysine residue and each one of these methylated states can have a different function. However, acetylation invariably leads to only one conclusion, the conversion of a dense heterochromatin to a loosely bound euchromatin. This happens by virtue of the negatively charged acetyl groups disturbing the interactions between positively charged (lysine and arginine) histone proteins and the negative phosphodiester DNA backbone, thus providing access to the synthesizing machinery. The reversal of these processes is performed by the enzymes histone demethylase and histone deacetylase. Histone deacetylases remove the acetyl residues on the lysine residues of histones making them wound back to DNA converting it into densely packed complex as represented in fig. 1.1 [72-74]. In addition to the contribution of these modifications to differential expression of genes, investigations revealed that they might be associated with the development of cancer by altering the expression of tumor suppressor genes. In addition to these modifications on histone proteins, modifications also occur on DNA as methylation. The process of methylation occurs on CpG sites and is brought about by the enzyme DNA methyltransferase. These mechanisms are topics of intense research as many studies highlighted the role of them in carcinogenesis.

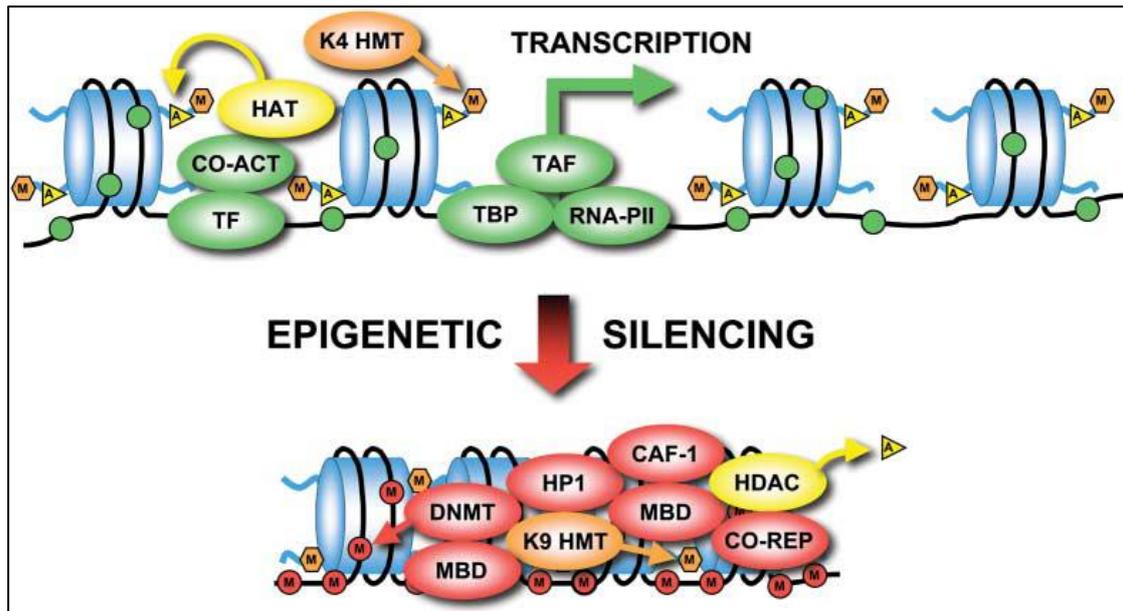

Figure 1.1 Epigenetic regulation of a gene

Proteins involved in the transcriptional activation and repression of a gene. Transcription factors (TF), co-activators (CO-ACT), histone acetyltransferase (HAT), lysine 4 histone methyltransferase (K4 HMT), TATA binding protein (TBP), TBP-associated factor (TAF) and RNA polymerase II (RNA-Pol II) are associated with transcriptional activation. DNA methyltransferase (DNMT), methyl-binding domain protein (MBD), heterochromatin protein 1 (HP1), histone 3 lysine 9 (K9 HMT), chromatin assembly factor-1 (CAF-1), histone deacetylases (HDAC), and co-repressor (CO-REP) are associated with transcriptional repression [74].

Molecules that could inhibit the above mentioned processes were used to study the mechanistic details of the epigenetic modifications and to cause changes leading to arrest the growth of cancer cells. Valproic acid is a compound that inhibits histone deacetylase enzyme, and has been extensively studied for its antineoplastic properties [75-78].

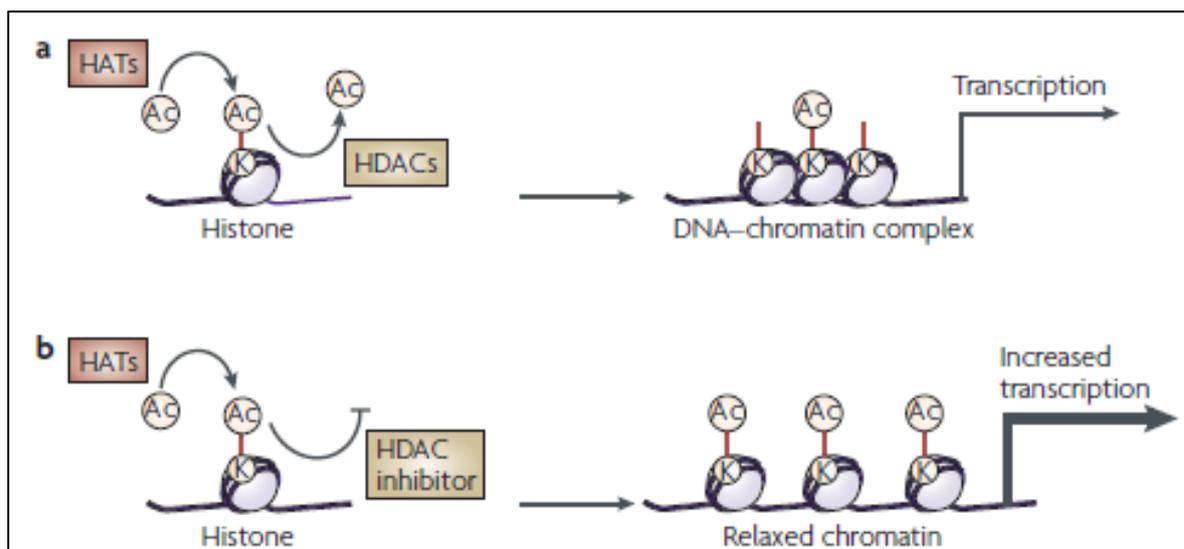

Figure 1.2 Impact of acetylation of histones on transcription

Equilibrium between acetylation and deacetylation effects the transcription of a gene. The acetylation of lysine (K) residues by histone acetyltransferase (HAT) and the selective removal of these acetyl groups by histone deacetylase (HDAC) results in an appropriate level of acetylation of histones which leads to the formation of a proper DNA-chromatin complex associated with transcription of selected genes (a). Inhibition of the deacetylation process leads to increased transcription (b) [79].

Similarly, a nucleoside analogue of cytidine, 5-azacytidine, has been found to be functionally active against DNA methylation process by inhibiting the enzyme DNA methyltransferase [80;81]. Azacytidine is converted to the compound 5-aza-2'-deoxycytidine (decitabine) which is the active compound responsible for this activity.

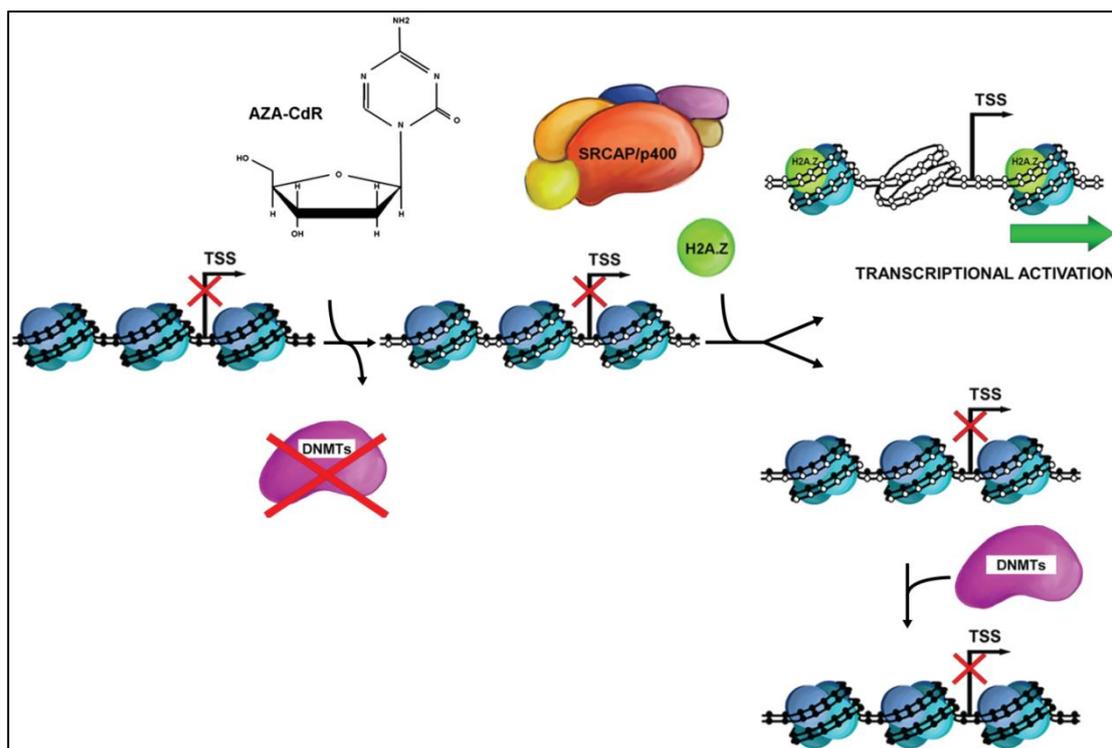

Figure 1.3 Inhibition of DNA methylation by 5-aza-2'-deoxy-cytidine (AZA-CdR)

Demethylation of a gene caused by inhibition of DNA methyltransferases (DNMTs) by 5-aza-2'-deoxy-cytidine (AZA-CdR) leads to the recruitment of proteins involved in gene reactivation such as the histone variant H2A.Z. H2A.Z recruitment at promoter regions is performed by the Snf2-related CBP activator protein (SRCAP) complex [82].

Apart from the methylation patterns on the whole DNA, methylation occurring specifically at the promoter region has been shown to effect the expression of a gene. Hypermethylation of promoter regions has been associated with lower expression of the gene [83-85]. Infact, the methylation patterns were found to be altered in cancer, wherein hypomethylation was observed in sequences of most of the genome while the genes involved in regulating processes crucial for normal growth patterns like cell cycle were effectively silenced by hypermethylation [86].

Such mechanisms have been reported to influence the uptake of therapeutically important molecules. Promoter methylation was reported to influence the expression of the uptake

transporter organic cation/carnitine transporter 2 (OCTN2) [87]. Similarly, DNA methylation repressed the promoter activity of organic anion transporter 3 (OAT3) [88].

1.9.2 Transcriptional regulation of gene expression

Epigenetic level of regulation of gene expression is followed by the transcriptional level, many times as a consequence of changes at the epigenetic level. As described above, conversion of a closed chromatin to an open one in most cases is followed by binding of proteins of the transcription machinery. Transcription factors are small proteins that bind to specific regions in the DNA around the start site of transcription. They are classified based on the sequences they recognize and bind to, and on the basis of their protein structure. They bind to sequences such as promoters, activators or silencers and this binding induces or hinders the formation of an active transcription complex [89-91]. Deviations in this tightly controlled mechanism have been implicated in various diseases including cancer [92]. The involvement of a lot of factors in contributing to the expression of a gene upon diverse stimuli made them one of the strategies for cancer treatment [93]. The involvement of transcription factors in the regulation of uptake transporters is a topic of intense research. Organic cation transporter 1, organic anion transporters 1 and 2 were shown to be activated by hepatocyte nuclear factor-4 α (HNF-4 α) [94-96]. Similarly the organic anion transporters 5 and 7 were activated by HNF-1 α [97]. The transcription factor BCL6 was found to activate the expression OAT2 [98].

1.9.3 MicroRNA based regulation of gene expression

At the post-transcriptional level, the level and translation of the messenger RNA are greatly influenced by a group of non-coding RNAs referred to as microRNAs. MicroRNAs are transcribed either from their own discrete genes or generated during the

splicing of the messenger RNAs [99]. There are multiple pathways of microRNA biogenesis including the canonical and noncanonical pathways. The microRNAs are transcribed as pri-microRNAs in the canonical pathway which undergo processing by Drosha and other proteins to become pre-microRNAs containing a stem-loop structure and are exported to the cytoplasm. These immature microRNAs are bound by Dicer and other proteins, culminating in the formation of a mature RNA induced silencing complex (RISC) [100;101].

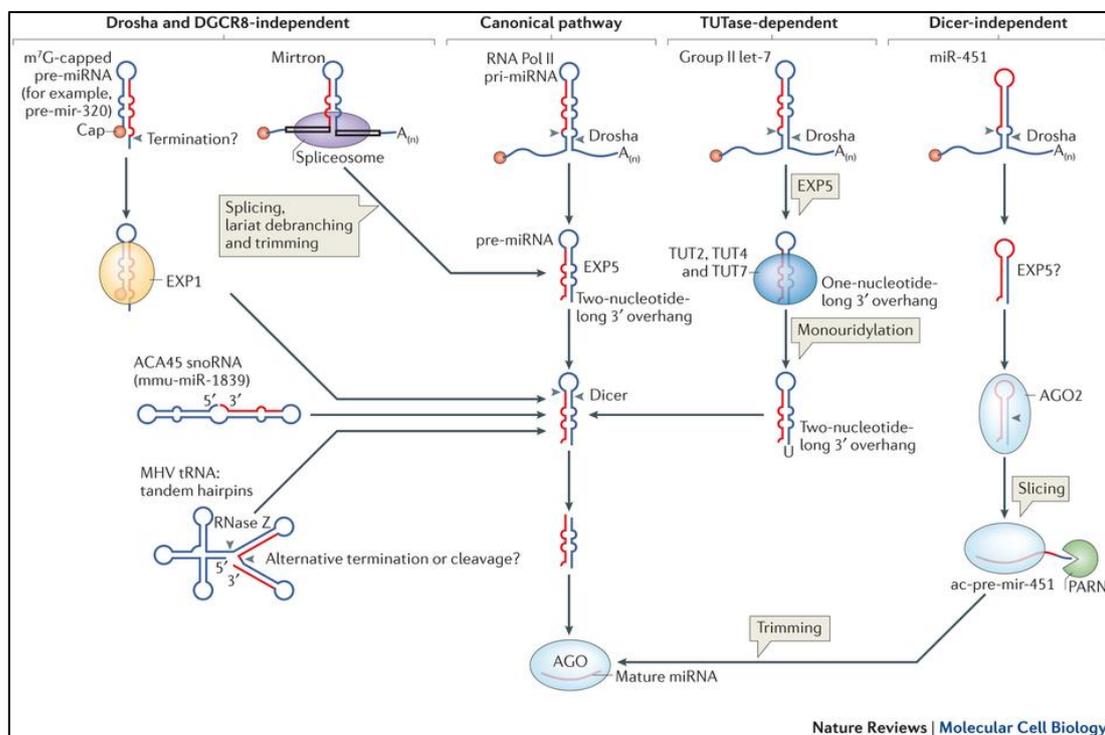

Figure 1.4 Multiple pathways of microRNA biogenesis

MicroRNAs are transcribed in the canonical pathway as primary microRNAs (pri-miRNA) with a cap, stem-loop and poly(A) tail. They are converted into pre-miRNA by the microprocessor complex (Drosha, DGCR8) in the nucleus and exported into the cytoplasm wherein the enzyme, Dicer, processes it further into miRNA duplex, one strand of this duplex is loaded onto RNA induced silencing complex (RISC). Some microRNAs are generated directly from transcription, while some are generated by splicing from mirtrons (generated from introns of mRNA of other

genes), and exported without the involvement of processing proteins in a Drosha and DGCR8-independent pathway. Some microRNAs are synthesized short and require additional action of a terminal uridylyl transferase (TUTase), a step required for efficient DICER action in TUTase dependent pathway. In yet another pathway independent of Dicer, mir-451 is generated as a stem-loop structure by Drosha and processed by Ago2 and poly(A)-specific ribonuclease (PARN) enzyme to a mature microRNA [101].

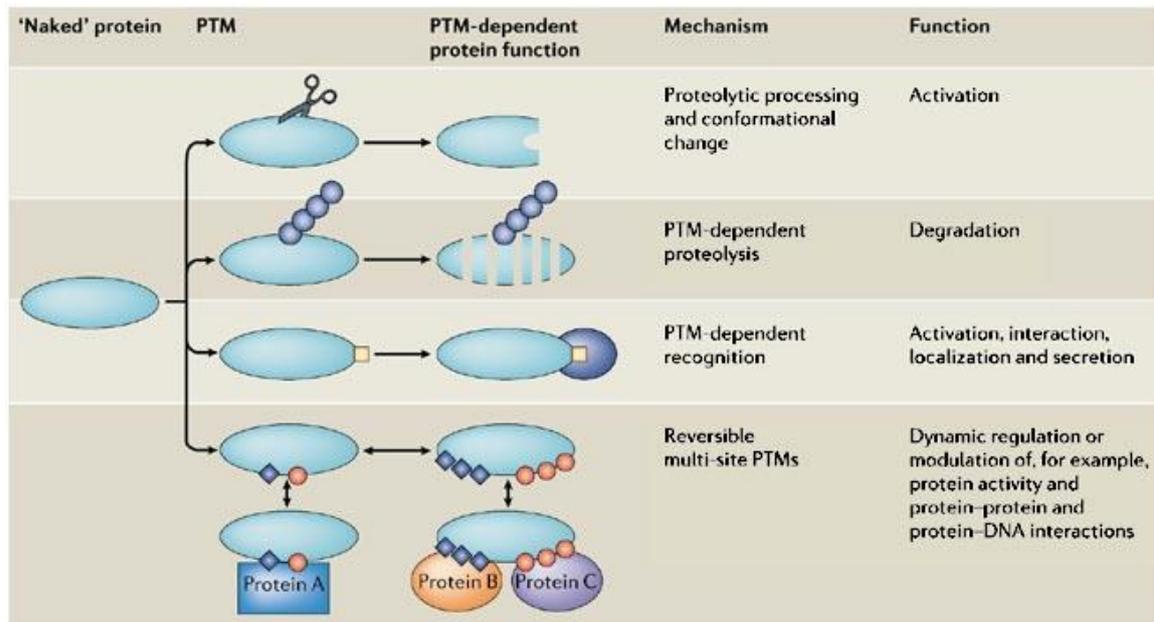

The mature microRNAs in the RISC are shown to bind to the 5' or 3' untranslated regions or even in the coding regions of messenger RNAs with complete or incomplete complementarity and this binding either triggers the degradation of mRNA or causes translational repression [99;102-104]. Degradation of mRNA was found to take place in specialized structures called P- bodies or cytoplasmic bodies [105;106]. Alternately, microRNA has also been shown to upregulate translation of mRNA [107-109]. It is worthwhile to mention here that the effect caused by microRNA in most of the cases is rather fine tuning the timing and expression level of the mRNA [110]. It has been seen that microRNA can have more than one target messenger RNAs [111] and likewise an mRNA can be regulated by more than one microRNA [112]. The binding of microRNA to messenger RNA in most cases was reported to be with incomplete complementarity. This makes it difficult to pinpoint which microRNA would bind to which messenger RNA and this quest led to the development of prediction algorithms. Many prediction programs were developed after studying the observed interactions between microRNA seed sequence and evolutionary conserved target sequence on mRNAs and algorithms were developed. Some of the prediction programs routinely used include TargetScan [113], DIANA-microT [114], miRanda [115], and PicTar [116]. A comparison of such algorithms revealed the accuracy of the prediction algorithms and that some programs have high correlation between the predicted targets with those experimentally found [117-

120]. Simultaneously, a number of experimental procedures were also developed and employed to judge the accuracy of the predictions made using *in silico* programs [121].

MicroRNA based regulation of expression is an emerging field of research and studies focused on the impact of such a regulation on the uptake transporters and hence cancer chemotherapy is being currently looked into as well. The microRNA mir-195-5p was shown to suppress the expression of the glucose transporter GLUT3 [122]. Similarly microRNA miR-133 was shown to regulate the expression of GLUT4 [123].

1.9.4 Post-translational mode of gene regulation

Once a protein is synthesized from messenger RNA, it often undergoes a series of changes including formation of a functional 3 dimensional structure with the aid of chaperones. Post-translational modifications confer operational regulation on a protein by phosphorylation, acetylation, glycosylation etc. Protein phosphorylation and dephosphorylation are the most common mechanisms employed by the cellular machinery during signal transduction. Phosphorylation, glycosylation, ubiquitination and other post-translational modifications have been shown to affect the function of many transporter proteins like OCT2, Ntcp etc. [124-129]. The other area of intense research, involving post translational modifications and protein-protein interactions, is the maintenance of the transporters on the plasma membrane in structures known as lipid rafts. Transporter membranes were often found to be localized to specialized areas on plasma membrane, regions rich in sphingolipids and cholesterol called lipid rafts and changes in constituents of lipid rafts altered their transport activity *in vitro* [130;131]. Protein-protein interactions with adaptor proteins like PDZK2 have been implicated in modulation of transporter activity [132;133].

Figure 1.5 Post-translational modifications (PTM) of proteins

Post-translational modifications of proteins lead to a variety of consequences such as activation, degradation, interaction with specific partners, either protein or DNA, secretion etc. [134].

1.10. Regulation of organic cation transporter 3

Organic cation transporter 3, encoded by the gene *SLC22A3*, is involved in the transport of positively charged molecules in a sodium independent manner. Considerable work has been done assessing the ability of OCT3 to transport physiologically and therapeutically important compounds. It is found to be expressed predominantly in kidney, liver, placenta, heart and skeletal tissues and to a lesser extent in brain and lung in humans [135-138]. It is involved in the uptake of physiological substances like histamine, serotonin, and exogenous substances like MPP, TEA, and ASP [139]. It was found to contribute to the regulation of salt-intake [140], uptake of the antineoplastic compounds melphalan, irinotecan, and vincristine [141], oxaliplatin [142], antipsychotic drug amisulpride [143], and also shown to interact with many antidepressants [144]. There

were changes in the expression of OCT3 in various carcinomas [141;145] and this factor, in addition to the important physiological role it plays, made the quest of mechanism of regulation of OCT3 expression, a matter of considerable interest. The changes in expression of OCT3 were observed to affect the transporter mediated accumulation of antineoplastic drugs in renal cell carcinoma [141].

The contribution of single nucleotide polymorphisms [146], methylation patterns [147] and the effects of kinases and other proteins on the expression and function of OCT3 were studied in detail [148-150]. However, the regulation of OCT3 by microRNAs and the impact of such a regulation on the function of OCT3 have not been looked into yet.

1.11. Objectives of the thesis

The objectives of this work are

- 1) To analyze the interactions of antineoplastic compounds with the SLC transporter proteins specifically expressed in hepatocytes namely, organic anion transporter 2 (OAT2), sodium taurocholate cotransporting polypeptide (NTCP), and organic anion transporting polypeptides 1B1 and 1B3 (OATP1B1 and OATP1B3).
- 2) To find out the possible factors responsible for the variable expression of organic cation transporter 3 in the renal carcinoma cells A498; ACHN, 786-O, and LN78.

3. Methods

3.1. Cell culture

Human embryonic cells stably transfected with organic anion transporter 2 (OAT2), sodium taurocholate cotransporting polypeptide (NTCP), organic anion transporting polypeptides 1B1 or 1B3 were cultured in DMEM high glucose medium. Renal carcinoma cells (RCCs) were grown in Q263 medium.

All the cells were cultivated in an incubator maintained at 37° C with 5% CO₂. At confluency, cells were washed with 3 mL of PBS and then incubated with 3 mL of trypsin-EDTA solution at 37° C for 5 min (RCCs) or for 2 min at room temperature for HEK based cells. The cells were pipetted into a 15 mL falcon containing 3mL of medium and centrifuged at 1000 RPM for 5 min at room temperature. The supernatant was discarded and the cells were supplemented with 1 mL of fresh medium. Depending upon the need they were either split for the next passage of culture or used for RNA isolation. For storage, cells were resuspended with ice cold medium containing 10% DMSO and transferred onto ice for 30 min and later stored in -80° C and liquid nitrogen.

3.2. Substrate uptake experiments

HEK293 cells carrying the vector alone (pcDNA) or the corresponding transporter gene were seeded at a density of 2×10^5 cells per well in poly-D-lysine coated 24 well plates and grown for 72 h in Quantum 286 medium containing penicillin and streptomycin. All substrate uptake assays were performed at 37° C in Hank's buffer solution containing Hank's balanced salt solution and 20 mM HEPES, pH 7.4 adjusted with 1N NaOH. Prior to the experiment, the cells were washed twice with PBS and then incubated in Hank's buffer until the start of experiment. The substrate solutions were prepared in Hank's

buffer, and along with the cells, were prewarmed for 5 min at 37° C. 5 µL of the substrate solution was taken as a standard to calculate the specific activity of the substrate.

After the desired time point, the uptake was terminated by washing thrice with ice cold PBS and the cells were lysed by incubation with 1N NaOH for 1h at room temperature. The lysates were transferred to scintillation vials and 2.5 ml of Rotiszint eco plus scintillation solution was added. The counts were obtained from a liquid scintillation counter TriCarb 2910TR. Data was analyzed using Microsoft Excel and SigmaPlot 11.

3.2.1 Time dependent uptake of [³H] labeled substrates

The uptake of [³H] labeled substrate was followed over a period of time in Hank's buffer containing a mixture of labeled and unlabeled substrate amounting to a desired concentration.

3.2.2 Concentration dependent uptake of radiolabeled substrates and determination of affinity constants

The uptake of radiolabeled substrate was measured at increasing concentrations of unlabeled substrate, and the affinity of the transporter protein for its respective substrate was calculated from the uptake values obtained. From three such experiments, the Michaelis-Menten constant, K_m was calculated.

3.2.3 Inhibition of transporter activity by antineoplastic agents

The ability of an antineoplastic compound to inhibit the uptake of the corresponding substrate of the transporter protein was used as an index to find out potential interactions between the compound and the transporter protein. The inhibition studies were performed with 100 µM of the antineoplastic compounds wherein the uptake was measured with a

substrate concentration of $1/10^{\text{th}}$ of the K_m value of the transporter protein for the corresponding substrate.

3.2.4 Concentration dependent inhibition of uptake of substrates in the presence of antineoplastic compounds

The affinity of the transporter protein for the antineoplastic compound was calculated from Dixon plot analysis. The uptake of the radiolabeled substrate was measured in buffer solutions containing two different concentrations of substrate both having identical concentrations of labeled substrate and an increasing amount of the antineoplastic compound.

3.2.4.1 Concentration dependent inhibition of OAT2 activity by the compounds bendamustine, irinotecan and paclitaxel

To determine the affinity of the transporter proteins for those antineoplastic compounds which inhibited the uptake of the corresponding substrate to less than 40 % of buffer control, the Dixon plot analysis was performed. For Dixon plot analysis of inhibition of OAT2 mediated uptake of [^3H] cGMP, the transport was performed at two different concentrations of cGMP; 1 μM (10 nM [^3H] labeled cGMP and 990 nM cold cGMP) and 10 μM cGMP (10 nM [^3H] labeled cGMP and 9.99 μM cold cGMP) in the presence of increasing concentrations of the respective cytostatic compound. The concentrations used for bendamustine and irinotecan were 0, 5 μM , 10 μM , 20 μM , 40 μM , 70 μM , 100 μM and 130 μM , and for paclitaxel, the concentrations were 0, 2.5 μM , 5 μM , 7.5 μM , 10 μM , 12.5 μM , 15 μM and 20 μM .

3.2.4.2 Concentration dependent inhibition of OATP1B1 activity by vinblastine and paclitaxel

The uptake of [³H] estrone-3-sulfate was measured in Hank's buffer solution containing 20 nM [³H] estrone-3-sulfate and either 230 nM or 2.48 μM unlabeled estrone-3-sulfate for 5 min in the presence of 0, 10 μM, 25 μM, 50 μM, 75 μM, 100 μM, 125 μM, and 150 μM of vinblastine, and 0, 0.1 μM, 0.25 μM, 0.5 μM, 0.75 μM, 1 μM, 1.5 μM, and 2 μM of paclitaxel.

3.2.4.3 Concentration dependent inhibition of OATP1B3 activity by antineoplastic compounds

In the case of OATP1B3, the uptake of [³H] CCK-8 was monitored in Hank's buffer solution containing 5 nM of [³H] CCK-8 and either 995 nM or 9.995 μM unlabeled CCK-8 in the presence of increasing concentration of the corresponding antineoplastic compound. The concentrations of 0, 10 μM, 25 μM, 50 μM, 75 μM, 100 μM, 125 μM and 150 μM were used for chlorambucil and vinblastine, 0, 1 μM, 2 μM, 3 μM, 4 μM, 5 μM, 7.5 μM and 10 μM for mitoxantrone; 0, 5 μM, 10 μM, 20 μM, 40 μM, 70 μM, 100 μM and 130 μM for vincristine, 0, 0.25 μM, 0.5 μM, 1 μM, 2 μM, 3 μM, 4 μM, and 5 μM for paclitaxel and 0, 1 μM, 2.5 μM, 5 μM, 7.5 μM, 10 μM, 15 μM and 20 μM for etoposide, respectively.

3.3. Apoptosis assay by determination of the Caspase-3 activity

Caspases are a family of enzymes that play an important role in the complex process of apoptosis. Most of the antineoplastic compounds used in this study invariably lead to cell death by apoptosis. To find whether the strong interactions observed in cis-inhibition experiments are associated with to the uptake of the antineoplastic compounds into the

cells, a specific assay for measuring the caspase-3 activity was performed. Bendamustine is an alkylating agent and is known to cause apoptosis in cells. So, an apoptosis assay was performed using the EnzChek Caspase 3-Assay kit as per the manufacturer's protocol with some modifications. Briefly, 2×10^5 cells were seeded in 24 well plates, grown for 72 h, and were incubated further with 100 μ M bendamustine in the culture medium for 12 h alone or in combination with 100 μ M probenecid. Cells were washed in PBS, trypsinised, and pelleted from the spent medium, PBS wash fraction, trypsinized fraction and pooled together to avoid possible loss of any cells. They were lysed in 50 μ l of lysis buffer (supplied in the kit) and subjected to a freeze thaw cycle with 5 min incubation in liquid nitrogen. After a spin at 5,000 rpm for 5 min, the supernatant was collected. 40 μ l of this supernatant was added to the substrate and incubated for 20 min in a dark place. The remaining 10 μ l was used for protein concentration determination by the Bradford method (Section 2.5). Fluorescence was measured in 80 μ l of the 1:10 diluted product in a Multi-plate reader Mithras LB 940. The relative fluorescence units (RFU) were normalized to protein concentrations obtained from Bradford estimation and the data is represented as % caspase-3 activity wherein the RFU obtained with untreated pcDNA cells was taken as 100%. Similar assays were also conducted with irinotecan and paclitaxel.

3.4. Evaluation the uptake of antineoplastic drugs in the cells by HPLC analysis

High performance liquid chromatography is a tool used for the separation of compounds based on the differential properties of the compounds in interacting with substances or phases differently, as judged by their partition coefficients. This method is highly sensitive and has been successfully used as a very reliable method to quantify various metabolites in cells. Fluorescence based detection of compounds in HPLC analysis of cell

lysates has the added advantage of specificity with a minimal background contribution to the signal observed.

The HPLC analysis was essentially performed as the uptake experiments mentioned earlier, albeit, in 100 mm plates. 3×10^6 cells were seeded in poly D-lysine coated plates and allowed to grow to confluency. Cells were washed with PBS thrice and incubated with Hank's buffer solution containing 100 μ M irinotecan or a mixture of 100 μ M irinotecan and 100 μ M cGMP in a 37° C water bath for 5 min. The transport was terminated by placing the plates in ice cold water and then aspirating the buffer followed by three washes with ice-cold PBS. The cells were scrapped using 1 mL of the mobile phase (40% methanol: 60% 0.1 M ammonium acetate and 0.01 M TBAHS pH 5.5) containing 20 μ M of the internal standard, camptothecin. The cell suspensions were lysed by sonication. 20 μ L of the lysates was separated for protein estimation and the rest was centrifuged at 13,000 rpm at 4° C for 20 min. The supernatants were filtered through 0.2 μ m syringe filters and subjected to HPLC analysis using a Zorbax Eclipse XDB-C8 column with 5 μ L injections. Irinotecan (CPT-11) and camptothecin (CPT) were detected by fluorescence with excitation maximum of 355 nm and emission maximum of 515 nm in a mobile phase containing 40% methanol: 60% 0.1 M ammonium acetate and 0.01 M TBAHS pH 5.5. Standard curves were plotted using increasing concentrations of the pure compounds irinotecan and camptothecin.

For measuring time dependent uptake of irinotecan, confluent cells in 100 mm culture dishes were washed twice with PBS and incubated in Hank's buffer solution containing 100 μ M irinotecan for 2, 4, 6, 8 or 10 min. The buffer was removed, the cells were washed with ice cold PBS three times, and the cells were collected by scraping them in 1 μ L of mobile phase and analyzed as described above.

3.5. Determination of Protein concentration

To normalize the amount of cell mass contributing to the observed effect, the amount of protein in the cell lysates was measured by Bradford method [151] with some modifications. Briefly, the lysates were diluted 1:20 with distilled water and 20 μ l of this solution was added to a 96 well plate followed by the addition of 200 μ l of Bradford reagent. The absorbance was measured at 595 nm in a Multi-plate reader Mithras LB 940. A standard curve was plotted from absorbance of 0, 50 μ g, 75 μ g, 100 μ g, 150 μ g, 200 μ g, 250 μ g and 300 μ g of BSA and the protein concentration of each test sample was calculated using the plotted standard curve of BSA, which is integrated in an evaluation table of Microsoft Excel.

3.6. Isolation of RNA

RNA was isolated from cells using the Qiagen RNA isolation kit or by Trizol method based on the experiment where it is used later.

3.6.1 Isolation of total RNA for qRT-PCR

Qiagen kit based RNA isolation was performed for RNA that was later used in qRT-PCR reactions. After the cells are confluent, they were pelleted as mentioned above. The cells were counted and 2×10^6 cells were used for the process. The cells were washed twice with PBS and were lysed with 350 μ L of lysis buffer (RLT buffer) containing 1% β -mercapto ethanol. The suspension was vortexed and an equal amount of 70% ethanol was added to it. The solution was transferred to a Qiagen filter column and was spun down at 10,000 RPM at room temperature for 15 s. The flow through was discarded and the column was washed with 700 μ L of wash buffer 1 (RW-1) and centrifuged at 10,000 RPM for 15 s. It was followed by a couple of washing steps with 500 μ L of wash buffer 2

(RW2) and spun down for 15s and 2 min, respectively. A high speed centrifugation step at 13,000 RPM for 1 min was applied to remove any residual wash solution. Then 30 μ L of RNase free water was added to the center of the column and the RNA bound to the column was eluted during a centrifugation step of 10,000 RPM for 30 s.

3.6.2 Isolation of total RNA using Trizol reagent

The Trizol method of isolation of RNA was performed for genome wide sequencing of microRNAs in the renal carcinoma cells A498, ACHN, 786-O and LN78 cells. Cells were seeded at a suitable density to yield ca. 3×10^6 cells at confluency. After washing twice with PBS, the cells were lysed on the culture dish itself by the addition of 3 mL of Trizol reagent (1 mL of Trizol per 1×10^6 cells). The suspension was thoroughly mixed, split into 2 parts into two separate 2 mL tubes and centrifuged at 11,300 RPM (12,000 x g) in a table top centrifuge at 4° C for 10 min. The supernatant was transferred into a fresh tube and left to stand at room temperature for 5 min. After 5 min, 0.3 mL of chloroform was added to the solution and the tubes were sealed tight and shaken vigorously for ca. 15 s and incubated at room temperature for a further 5 min. The samples were spun down at 11,300 RPM for 15 min at 4° C and the upper (aqueous) phase containing RNA was carefully transferred to a fresh tube without disturbing the white interphase (protein). The RNA present in the solution was precipitated by the addition of 0.75 mL of isopropanol and 1 μ L of GlycoBlue (a dye used to stain the RNA pellet). The samples were then incubated overnight in -20° C. They were centrifuged at 11,300 RPM for 30 min at 4° C. The supernatant was removed by pipetting and the pellet was washed with 1.5 mL of 75% ethanol and centrifuged at 11,300 RPM for 5 min at 4° C. The wash step was repeated again and the RNA pellet obtained was dried at 37° C. The dry pellet was dissolved later by pipetting in 50 μ L of RNase-free water.

3.6.3 Isolation of small RNA enriched fraction

The small RNA fraction of the RNA pool was specifically enriched using the mirVana miRNA isolation kit. Confluent cells were harvested and 2×10^6 cells were separated for small RNA enrichment. The cells were washed twice in PBS and the cell pellets were resuspended in 600 μL of lysis/binding buffer supplied in the kit and thoroughly vortexed. To this suspension, 60 μL of microRNA homogenate additive is added and mixed by vortexing. After an incubation of 10 min on ice, 600 μL of acid-phenol: chloroform mixture was added and vortexed for 45 s to mix. The mixture was centrifuged at 13,000 RPM for 5 min at room temperature. The upper aqueous phase was removed without disturbing the lower phase into a fresh tube and the volume was measured. To this solution, $1/3^{\text{rd}}$ volume of 100% ethanol was added and thoroughly vortexed. This mixture was passed through a filter cartridge (700 μL at a time) and the flow through was collected after a centrifugation step of 10,000 RPM for 15 s. The volume of the filtrate was measured and $2/3^{\text{rd}}$ volumes of 100% ethanol was added to this mixture which contains the small RNAs and mixed thoroughly. This solution is passed through a second filter cartridge and centrifuged at 10,000 RPM for 15 s and the filtrate is discarded. Both the filter membranes were then washed to retrieve the larger length RNAs and the smaller length RNAs, respectively. The filter cartridges were washed with 700 μL of microRNA wash solution 1 and centrifuged for 10 s at 10,000 RPM followed by two washes with 500 μL of wash solution 2/3 and centrifugation steps of 10,000 RPM for 10 s. The cartridges were given a spin to remove residual liquid and the RNA bound to the filters was later eluted by the addition of 100 μL of sterile water preheated to 95°C and a centrifugation at 13,000 RPM for 30 s.

3.7. Determination of concentration of RNA

1 μ L of RNA was added to 9 μ L of sterile water and the absorbance ratio of $A_{260/280}$ and the concentration was measured thrice for each sample. The average of the three readings was calculated as the total RNA concentration for future experiments.

3.8. Synthesis of complimentary DNA (cDNA)

2 μ g of RNA was used to prepare cDNA in a volume of 7 μ L in a 200 μ L PCR tube. 1 μ L of 10 mM oligo dT primer was added to the PCR tube and the mixture was subjected to annealing at 70° C for 10 min and then at room temperature. Meanwhile, a master mix was prepared with 4 μ L of complete buffer containing (250 mM Tris HCl pH 8.3, 500 mM KCl, 15 mM MgCl₂, and 50 mM DTT), 1 μ L of dNTPs, a volume containing 200 U of Superscript reverse transcriptase and 6.6 μ L of sterile water to a total volume of 12 μ L per reaction. The mixture was calculated for n + 1 reactions, where n is the number of reactions in the assay. The reaction mixture was mixed well by pipetting and was transferred to the annealing mixture and subjected to cDNA synthesis step with conditions of 37° C for 1h and 70° C for 10 min. The cDNA obtained was either stored in -20° C or used immediately for the qRTPCR reaction.

3.9. Quantitative RT-PCR

To measure the expression of the gene of interest, a qRTPCR reaction was performed using the cDNA synthesized. For all experiments aimed at finding the expression of OCT3, GAPDH was used as an internal control. Similarly, for experiments with objective of evaluating the expression status of microRNAs in the cells, the small nucleolar RNA, RNU43 and the microRNA hsa-mir-103 were used as internal controls. The 20 μ L cDNA prepared was diluted to a volume of 63 μ L. 1 μ L of primer of the corresponding gene was

added to 10 μ L of 10 X TaqMan master mix followed by 9 μ L of the diluted cDNA. The reaction mixture was mixed well by pipette, briefly centrifuged and then subjected to qRT-PCR with conditions of 50° C for 10 min, 95° C for 2 min, followed by 40 cycles of 95° C for 15 s and 60° C for 1 min. The plate sample values were obtained from the MxPro software and the data was plotted using Microsoft Excel.

3.10. Disruption of DNA methylation using azacytidine

Methylation of a DNA in vivo confers it to remain transcriptionally silent. There are many synthetic compounds which can block this process thus making the genes active; azacytidine is one such compound. Since the ACHN cells have less expression of OCT3, we performed the azacytidine based inhibition of DNA methylation on these cells, to check whether a transcriptional block is responsible for the low expression.

A498 and ACHN cells were seeded in 6 well plates at a density of 3×10^5 cells per well in 4 mL medium. After 24 h, ACHN cells were treated with 5 μ M, 15 μ M and 25 μ M of 5 Aza 2' deoxy-cytidine. The medium was changed with fresh 5 Aza 2' deoxy-cytidine every 24 h for a total of 72 h as the compound is highly unstable. RNA was isolated (Section 2.6.1) from these cells along with the untreated A498 and ACHN cells and cDNA was prepared, followed by a qRT-PCR reaction to check the levels of expression of OCT3 in them (Section 2.8 and 2.9).

3.11. Inhibition of histone deacetylase using valproic acid

Addition of acetyl groups on the lysine residues of histones renders them less affine to the negative phosphodiester backbone of DNA making the gene transcriptionally active and reversal of this process by histone deacetylases (HDACs) leads to a transcriptionally

inactive state of the gene. Inhibition of histone deacetylases using compounds such as valproic acid has been widely used for inhibition of HDACs.

Inhibition of histone deacetylases was performed using valproic acid in ACHN cells which have low OCT3 expression to check whether this results in higher expression of OCT3.

A498 and ACHN cells were seeded at a density of 3×10^5 cells per well in 4 mL medium and grown for 72 h in 6 well plates. They were incubated for a further 24 h with 0.5 mM, 5 mM or 10 mM valproic acid. The cells were harvested and the RNA was isolated from them along with untreated A498 and ACHN cells. cDNA was prepared from the RNA and a qRTPCR reaction was performed to check the levels of expression of OCT3.

3.12. Analysis of methylation status of promoter of SLC22A3 gene by Ion Torrent Sequencing

The methylation status of a promoter is an indication of whether a gene is transcriptionally active or not. There are various methods to determine the methylation status of a gene. Recent advances in the sequencing methods led to the development of high throughput processes aimed to achieve high sensitivity and a simpler work flow. One such method is the Ion torrent sequencing. The work flow is illustrated in fig. 2.1. As depicted in the figure, the method involves the construction of library, followed by preparation of template for sequencing followed by sequencing. Prior to the construction of the library, the whole DNA was extracted and bisulfite treated, followed by the amplification of desired fragments.

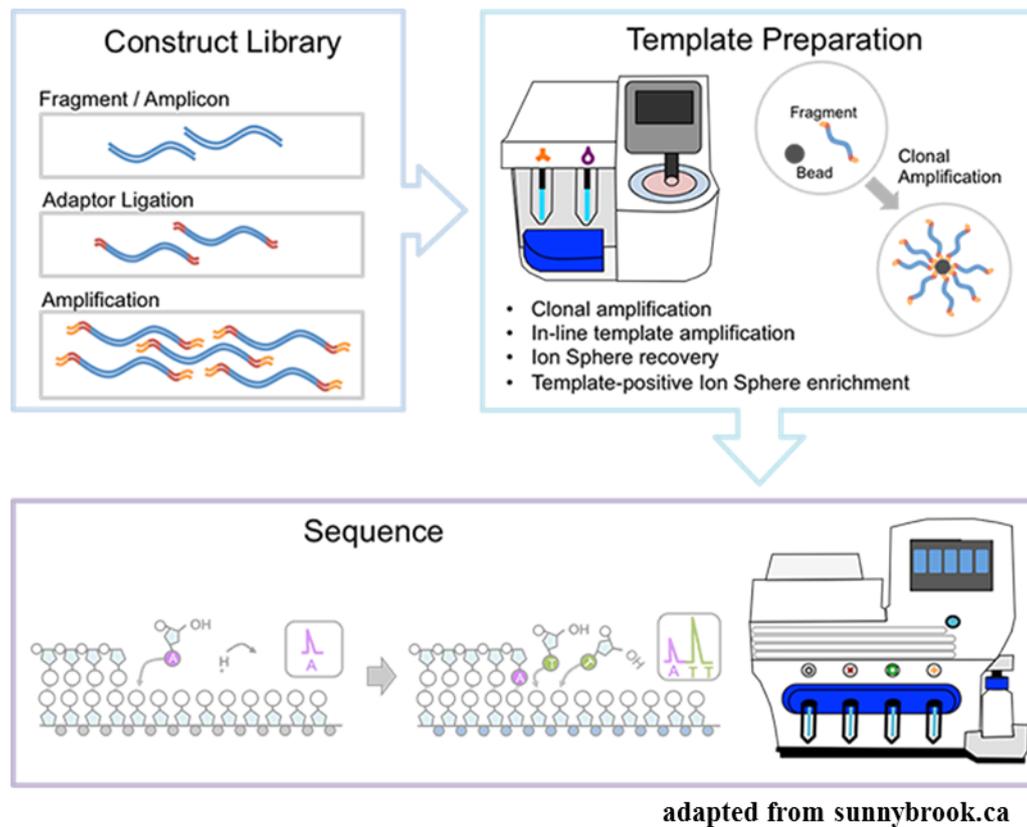

Figure 2.1 Work flow of ion torrent sequencing

The desired fragments are amplified by emulsion PCR on the ion sphere particles and loaded onto a chip. During sequencing the nucleotides are sequentially flushed into and out of the wells. Whenever a nucleotide is added, there is a release of proton leading to the local change of pH that is detected by a sensor and this signal is converted into a digital signal.

3.12.1 Extraction and bisulfite treatment of DNA

Bisulfite treatment of total DNA is the core step of many of the procedures aimed at finding the methylation status of a gene, the underlying mechanism being sodium bisulfite treatment would convert all unmethylated cytosines into uracil. When sequenced,

this converted DNA would reveal which cytosines were methylated and which ones were unmethylated.

2×10^6 cells of all the four RCCs were harvested and along with the human renal cortical epithelial cell pellet were subjected to DNA extraction protocol using an automated QIAcube system. The extracted DNA was estimated in a nanophotometer. 3 μL of eluted DNA was used for the estimation. 1 μg of the isolated DNA was taken into a fresh tube and the volume was raised to 20 μL with sterile double distilled water, followed by the addition of 85 μL of bisulfite solution and 35 μL of DNA protect buffer.

This mixture was vortexed and subjected to a bisulfite reaction in the QIAcube automated system using the protocol supplied by the manufacturer. The reaction was performed in the following steps; a denaturation step at 95° C for 5 min, an incubation at 60° C for 15 min followed by another denaturation step at 95° C for 5 min followed by an incubation for 15 min at 60° C and then at room temperature until the next step.

The treatment was soon followed by the cleanup procedure of bisulfite treated DNA. This process was performed in the QIAcube automated system under the protocol “cleanup of bisulfite converted DNA”. The process involves immobilizing the DNA on the Qiagen spin columns and removing all the reaction constituents of the bisulfite reaction. It involved the following steps: the bisulfite treated DNA was transferred into a 1.5 mL tube, followed by the addition of 250 μL of 100% ethanol and pulse vortexed for 15 s. After a brief spin, the mixture was passed through a MinElute DNA spin columns by centrifugation at full speed for 1 min. The column was washed with 500 μL of wash buffer (BW) followed by centrifugation at full speed for 1 min. It was followed by a desulfonation step wherein the columns were incubated with 500 μL of desulfonation buffer (BD) for 15 min at room temperature. After a full speed centrifugation step for 1

min, the columns were washed twice with 500 μL of BW, followed by the addition of 250 μL of 100% ethanol to the columns and centrifuged at full speed for 1 min. The columns were transferred into fresh 2mL tubes and centrifuged at full speed for 1 min to remove any residual liquid. The DNA bound to the columns was then eluted by incubating the columns with 15 μL of elution buffer at room temperature for 1 min, followed by centrifugation of the columns at 12,000 RPM for 1 min. The eluted DNA was measured in a nanophotometer.

3.12.2 Amplification of desired fragments and library preparation

The primers were designed using the software Methyl Primer Express software. 3 μL of the bisulfite DNA obtained in each sample was pooled and the 15 μL was subjected to a gradient PCR in the range of 50° C to 70° C, with the primers designed to regions 1 and 2 of the promoter of OCT3. The composition of the reaction mixture for 3 reactions was

Component	volume
2X HotStart master mix	15 μL
Forward primer (10 μM)	1.2 μL
Reverse primer (10 μM)	1.2 μL
Water	5.6 μL
Bisulfite treated DNA	7 μL
Total volume	30 μL

Table 3.1 Reaction mixture of gradient PCR for amplification of promoter regions 1 and 2 of SLC22A3

10 μ L of the mixture was loaded in wells and PCR reaction was performed in the following steps

Step	No. of cycles	Temperature	Duration
Step 1	1	95° C	15 min
Step 2	50	95	30 s
		50-70	30 s
		65	2 min
Step 3	1	65	1 min
Step 4	1	8	infinite

Table 3.2 PCR conditions for the amplification of promoter regions 1 and 2 of SLC22A3

After the reaction is completed, the PCR products were mixed with 2 μ L of loading dye and analyzed in a 2% agarose gel. After the annealing temperature was set, 19 ng of bisulfite treated DNA from each sample was used to amplify the regions of interest and the PCR products were analyzed in a 2% agarose gel. Once all the amplified products were obtained, a library was prepared using 1:200 dilution of the obtained PCR product. Library preparation confers to the identification of each fragment of amplified DNA from each sample as a unique entity by the sequencer. To achieve this process, the amplified fragments were subjected to further PCR reactions with primers containing sequences called barcode and adaptor sequences. The barcode is specific for each fragment and is of 9 or 10 nucleotides length, followed by an adaptor which is 4 nucleotides length and is the same sequence for all the primers which is the start point for the amplification. This sequence is followed by specific sequence of forward and reverse primers of fragments 1 and 2 respectively. With the primers, an adapter PCR reaction was performed. The reaction mixture for this reaction for a single reaction was as follows

Component	volume
2X HotStart master mix	15 μ L
Barcoded forward primer (10 μ M)	1.2 μ L
Reverse primer (10 μ M)	1.2 μ L
Water	5.6 μ L
PCR product (1:200 diluted)	7 μ L
Total volume	30 μ L

Table 3.3 Reaction mixture for adapter PCR

The reaction mixture was subjected to a PCR reaction containing the following steps

Step	No. of cycles	Temperature	Duration
Step 1	1	95° C	15 min
Step 2	14	95	30 s
		50	30 s
		65	2 min
Step 3	1	65	5 min
Step 4	1	8	infinite

Table 3.4 PCR conditions for the amplification of barcoded fragments of promoter regions 1 and 2 of SLC22A3

The products from this PCR were also analyzed on a 2% agarose gel.

3.12.3 Quantification of library

7 μ L of the each adaptor PCR product from each fragment was separately pooled followed by the addition of 10 μ L of loading dye and the mixture was resolved on a 2% agarose gel. The fragments 1 and 2 were excised from the gel and then extracted from the

gel using the protocol of gel extraction of DNA in the QIAcube automated system. The two fragments were pooled and quantified by a quantitative PCR reaction.

The pooled PCR products were diluted to 1:2000 and 1:20000 by the dilution scheme:

5 μ L of product + 495 μ L of water	1:100 dilution
50 μ L of 1:100 diluted product	
+ 950 μ L of water template)	1:20 dilution (used as 1:2000)
10 μ L of 1:2000 template	
+ 90 μ L of water template)	1:10 dilution (used as 1:20000)

Using the diluted templates, the qPCR reaction was set up. The master mix was prepared such that each reaction was performed in triplicates along with the control library (*E. coli* DH10B control supplied with the kit). The number of reactions required was calculated accordingly and the reaction was set up with the following composition for 1 reaction

Component	volume
RNase-/DNase - free water	3.86 μ L
GeneRead qPCR SYBR green Mastermix	5.68 μ L
Primer mix (10 μ M)	0.45 μ L
Final volume	10 μ L
Template	3 μ L

Table 3.5 Reaction mixture for qPCR of amplified barcoded fragments

The plate was sealed with an adhesive tape and the PCR was run with an SDS 2.4 application template PCR program. Using the software the concentration of template was obtained which was then multiplied to the dilution factor and a factor of 0.000198

(corresponding to a library of average size of 300 bp) and the concentration of the library was obtained as ng/ μ L.

3.12.4 Ion torrent sequencing

For the next generation sequencing protocol of Ion Torrent sequencing, the templates are to be adhered onto ion sphere particles which are then loaded onto a chip in which the sequencing by synthesis reaction is performed.

3.12.4.1 Preparation of template positive Ion Sphere Particles (ISPs)

The template positive ion sphere particles were prepared using the Ion One Touch system. The process involves an emulsion PCR where in a DNA molecule is amplified on an ion sphere particle in an emulsion containing all the components required for DNA synthesis, and multiple cycles of this process leads to clonal amplification of the desired fragments on the ion sphere particle. All the reactions components were added sequentially as per the manufacturer's protocol as depicted in the following table

Component	volume
Nuclease free water	280 μ L
Ion One Touch 2x reagent mix	500 μ L
Ion One Touch enzyme mix	100 μ L
Diluted library	20 μ L
Total volume	900 μ L

Table 3.6 Reaction mixture for emulsion PCR to prepare template positive ISPs

To this mixture, 100 μL of Ion One Touch Ion Sphere Particles were added and the mixture was mixed well and loaded into the sample port of the Ion One Touch reaction filter assembly. Then 1 mL of Ion One Touch reaction oil was added into the sample port, followed by the addition of another 500 μL of the oil. After performing the run, the samples were centrifuged and the template positive ISPs were recovered. The template positive ISPs were transferred into 1.5 μL LoBind tubes. The supernatant was carefully removed leaving a 50 μL volume and the pellets were resuspended slowly with pipette, pooled and the volume was raised to 1 mL with wash buffer and centrifuged at 15,500 g for 2.5 min removing all but 100 μL of the supernatant. The pellet was vortexed and proceeded further for the enrichment of the ISPs.

3.12.4.2 Enrichment of template positive Ion Sphere Particles

Enrichment of template positive ISPs is performed to remove the unbound DNA and ghost ion sphere particles (which have no DNA bound to them) and potentially enrich those ISPs which have amplified DNA bound to them. This is achieved by incubation of the template positive ISPs (with biotinylated primers) with streptavidin beads and later washing them off after enrichment. A fresh melt off solution was prepared by mixing 865 μL of nuclease free water, 125 μL of 1M NaOH, and 10 μL of 10% Tween 20 solution. The Dynabeads MyOne streptavidin C1 beads were resuspended in 130 μL of MyOne beads wash solution. All the solutions were all placed in their designated wells in an 8 well strip and the run was performed resulting in the collection of enriched template positive ISPs. The collected suspension was spun down at 15,500 x g for 1.5 min, washed with 200 μL of Ion One Touch wash solution, mixed well with pipette and centrifuged at 15,500 x g for 1.5 min. After making sure that there are no beads left, the supernatant was removed leaving 10 μL of it with the pellet. The volume was raised to 100 μL with Ion

One Touch wash solution and the pellet was resuspended and ready to be loaded onto the chip for the run.

3.12.4.3 Sequencing the template positive Ion Sphere Particles

Meanwhile, the Ion Torrent PGM sequencer was initialized as per the manufacturer's instructions. Half of the volume of obtained enriched template positive ISPs was transferred to a fresh 0.2 mL tube followed by the addition of 5 μ L of control Ion Sphere Particles. The solution was centrifuged at 15,500 x g for 2 min and the supernatant was removed leaving 3 μ L with the pellet. 3 μ L of sequencing primer was added and the pellet was suspended with pipette. The tube was placed in a thermocycler and a run was performed with 95° C for 2 min and 37° C for 2 min. Meanwhile, a check was performed on the chip which is to be loaded with the template positive ISPs as per the guidelines provided in the protocol. To the reaction mixture, 1 μ L of Ion PGM sequencing 200 v2 polymerase was added to a final volume of 7 μ L, mixed and incubated for 5 min at room temperature. The solution was loaded onto an Ion 314 chip at a rate of ca. 1 μ L/ s and the chip was centrifuged for 30 s. The solution was pipetted in and out of chip, centrifuged and all the liquid was removed from the chip. Then the run was performed.

3.13. Computational algorithms used to predict microRNAs binding to 3' UTR of OCT3

There are many prediction programs which predict microRNAs binding to the 3' and 5' untranslated regions (UTRs) of mRNA of gene of interest. The prediction programs used for data mining were PICTAR, DIANA microT V3.0, TargetScan Human V 5.2, microRNA.org and EIMMo. All the microRNA species which were predicted to bind to the 3' UTR of OCT3 mRNA were collected as a data pool and such microRNA species

which were predicted by more than 2 of these programs were shortlisted for further experimentation.

3.14. Statistical analysis

All the statistical analysis was done using Microsoft Excel 2010 and SigmaPlot 11. *p* values were calculated using the paired samples student's *t* test.

3.15. Determination of molecular characteristics of the antineoplastic drugs using MarvinSketch software

MarvinSketch (version 14.7.28.0), 2014, from ChemAxon (<https://www.chemaxon.com>) was used to determine the molecular characteristics of the antineoplastic compounds used in the study. All the molecular structures were downloaded as molfiles, available from the chEMBL database. The parameters obtained using the software, which recognizes molfiles, include polar surface area, logP value, logD value, existence of a compound in various ionization states, their percentages, and net charge at different pH values.

4. Results

4.1. Interaction of Organic anion transporter 2 with antineoplastic compounds

Functionally characterized HEK cells stably expressing OAT2 were obtained from Dr. Saskia Flörl, PortaCellTec GmbH. From initial experiments conducted by PortaCellTec, the time of cGMP uptake chosen was 5 min and the K_m value was calculated to be 101.4 μM . So, the inhibition studies were performed wherein the uptake time was 5 min and the concentration of substrate was 10 μM .

4.1.1 Inhibition of OAT2 mediated cGMP uptake by antineoplastic compounds

The uptake of [^3H] labeled cGMP into OAT2-HEK cells was measured in the presence of 100 μM of the antineoplastic drugs for 5 min. Uptake of [^3H] cGMP in the absence of any antineoplastic compounds was calculated to be 62.4 ± 1.3 pmol/ 5 min. This absolute value was regarded, in each independent experiment, as 100% and the uptake value in the presence of antineoplastic compounds is represented as percentage of this value. Significant changes were observed in the uptake of [^3H] labeled cGMP into OAT2-HEK cells in the presence of many of the antineoplastic drugs tested and are presented as interactions with different classes of antineoplastic compounds based on their mechanism of action.

4.1.1.1 Inhibition of OAT2 mediated cGMP uptake by alkylating agents

Among alkylating agents, melphalan inhibited the uptake significantly by 20.7 ± 1.9 %, bendamustine by 86.7 ± 0.7 %, chlorambucil by 38.9 ± 1.2 % and busulfan by 21.7 ± 2.1 % of its buffer control (Fig. 4.1). The compounds cyclophosphamide, trofosfamide,

ifosfamide, treosulfan and thioTEPA did not cause any significant change in the uptake compared to the buffer control.

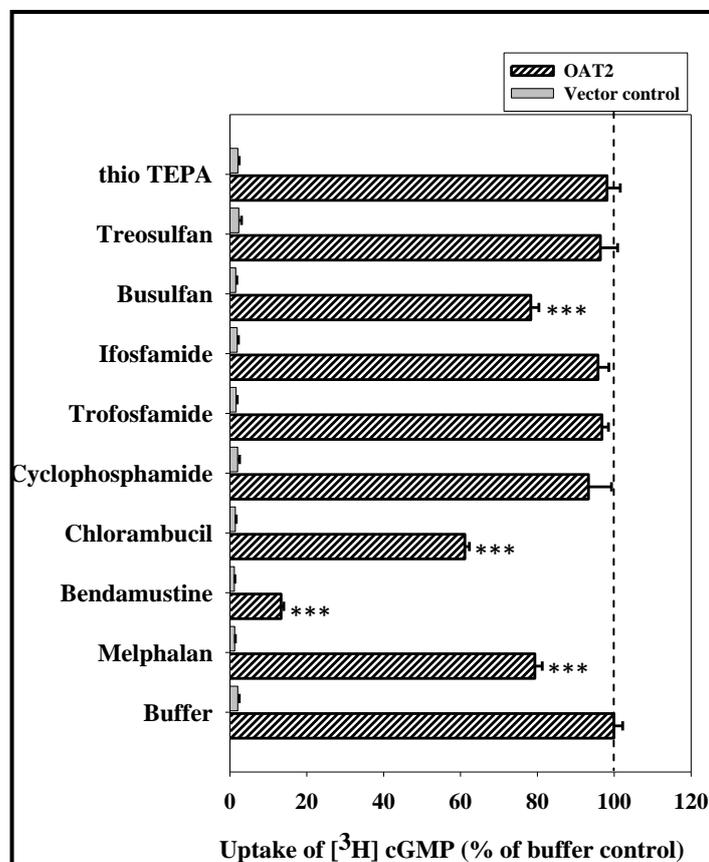

Figure 4.1 Inhibition of OAT2 mediated uptake of [³H] cGMP in the presence of alkylating agents. The uptake of [³H] cyclic GMP was monitored in a buffer system containing 10 nM [³H] cyclic GMP and 990 nM unlabeled cGMP in the presence or absence of 100 μ M of the alkylating compounds in OAT2 transfected HEK cells and vector transfected HEK cells. Data represent mean \pm SEM of 3 independent experiments with 3 repeats each. *** represents p value < 0.001 .

4.1.1.2 Inhibition of OAT2 mediated cGMP uptake by antimetabolites

Among the antimetabolites, the compounds, methotrexate, gemcitabine and fluoroadenine reduced the uptake of OAT2 mediated uptake of [³H] cGMP significantly by $25.6 \pm 2.9\%$, $9.5 \pm 2.3 \%$ and $23.1 \pm 1.9 \%$ of buffer control, respectively (Fig. 4.2). The

antimetabolites cytosine arabinoside, 5-fluorouracil, fludarabine and cladribine did not affect the transport activity.

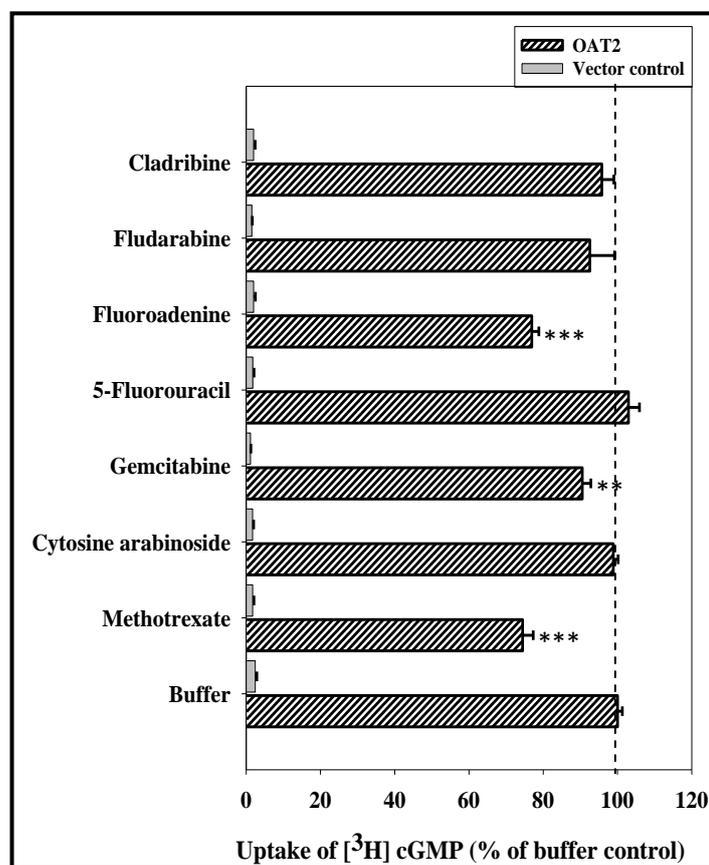

Figure 4.2 Inhibition of OAT2 mediated uptake of [³H] cGMP in the presence of antimetabolites. The uptake of [³H] cGMP was monitored in a buffer system containing 10 nM [³H] cyclic GMP and 990 nM unlabeled cGMP in the presence or absence of 100 μM of the antimetabolites in OAT2 transfected HEK cells and vector transfected HEK cells. Data represent the mean ± SEM of 3 independent experiments with 3 repeats each. ** represents *p* value < 0.01, *** represents *p* value < 0.001.

4.1.1.3 Inhibition of OAT2 mediated cGMP uptake by intercalating agents and mitotic inhibitors

Incubation of the cells with doxorubicin, mitoxantrone and vinblastine did not cause any significant effect on the OAT2 mediated uptake of [³H] cGMP whereas vincristine caused

a marginal increase of the uptake by 5.0 ± 1.5 % whereas paclitaxel caused a strong inhibition of the uptake by 83.7 ± 0.5 % of buffer control (Fig. 4.3).

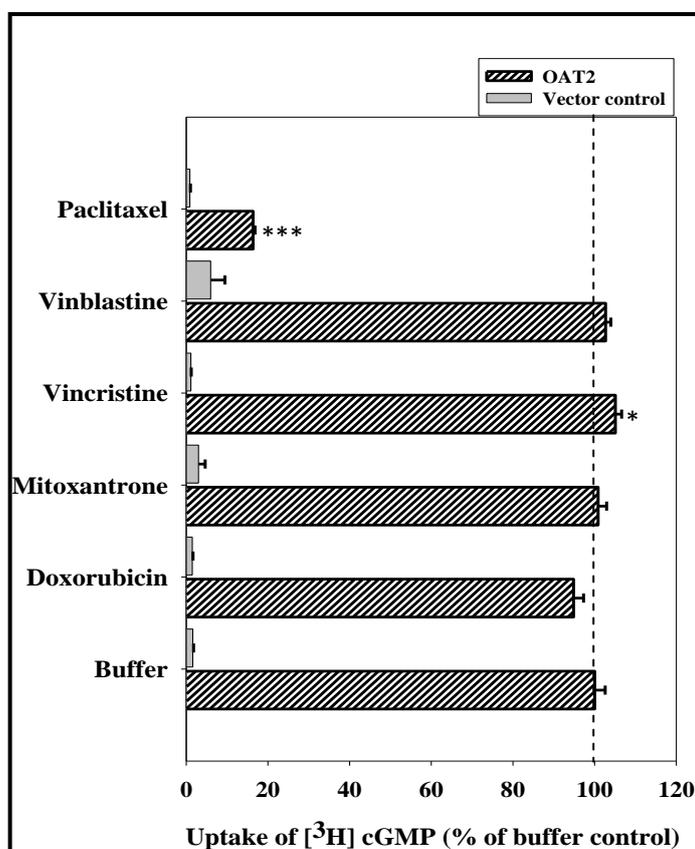

Figure 4.3 Inhibition of OAT2 mediated uptake of [³H] cGMP in the presence of intercalating agents and mitotic inhibitors. The uptake of [³H] cGMP was monitored in a buffer system containing 10 nM [³H] cyclic GMP and 990 nM unlabeled cGMP in the presence or absence of 100 μ M of the intercalating agents and mitotic inhibitors in OAT2 transfected HEK cells and vector transfected HEK cells. Data represent the mean \pm SEM of 3 independent experiments with 3 repeats each. * represents p value < 0.05 , *** represents p value < 0.001 .

4.1.1.4 Inhibition of OAT2 mediated cGMP uptake by topoisomerase inhibitors and compounds targeting hormone receptors

The topoisomerase inhibitors irinotecan and etoposide reduced the uptake by 87.8 ± 0.4 % and 32 ± 1.2 % respectively. Tamoxifen caused an inhibition of OAT2 mediated

uptake of cGMP by 12.7 ± 2.2 % of buffer control while the compounds prednisone and clodronic acid did not cause any significant effect (Fig. 4.4).

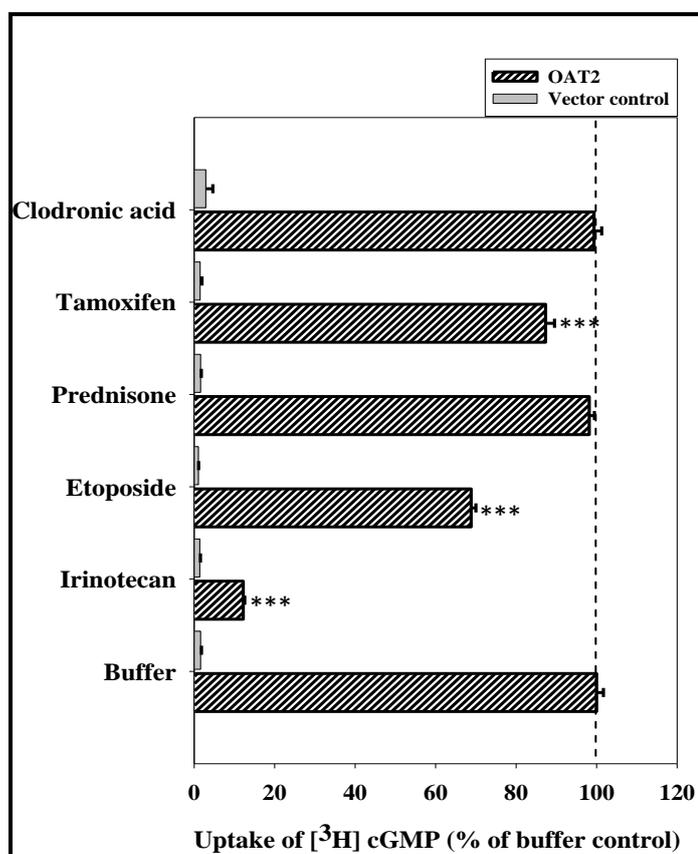

Figure 4.4 Inhibition of OAT2 mediated uptake of [³H] cGMP in the presence of topoisomerase inhibitors and compounds acting on hormone receptor targets. The uptake of [³H] cGMP was monitored in a buffer system containing 10 nM [³H] cyclic GMP and 990 nM unlabeled cGMP in the presence or absence of 100 μ M of topoisomerase inhibitors and hormone receptor targeters in OAT2 transfected HEK cells and vector transfected HEK cells. Data represent the mean \pm SEM of 3 independent experiments with 3 repeats of each sample. *** represents p value < 0.001 .

4.1.2 Concentration dependent inhibition of antineoplastic compounds on OAT2 mediated [³H] cGMP uptake

In order to determine the affinity of OAT2 for selected antineoplastic drugs, which inhibited uptake to less than 40 % of buffer control, we employed the Dixon plot analysis. Measurement of the uptake of [³H] labeled cGMP at 1 μ M and 10 μ M cGMP was performed in the presence of increasing concentrations of the corresponding compound.

4.1.2.1 Concentration dependent inhibition of OAT2 mediated [³H] cGMP uptake by bendamustine

For measuring the affinity of OAT2 for bendamustine, the uptake was measured in the presence of increasing concentrations of bendamustine in the range of 0 – 130 μ M. Plots of the reciprocal of velocity of uptake on Y axis over the concentration of the antineoplastic compound on X axis revealed the K_i value of OAT2 for bendamustine to be $43.3 \pm 4.33 \mu$ M (Fig. 4.5).

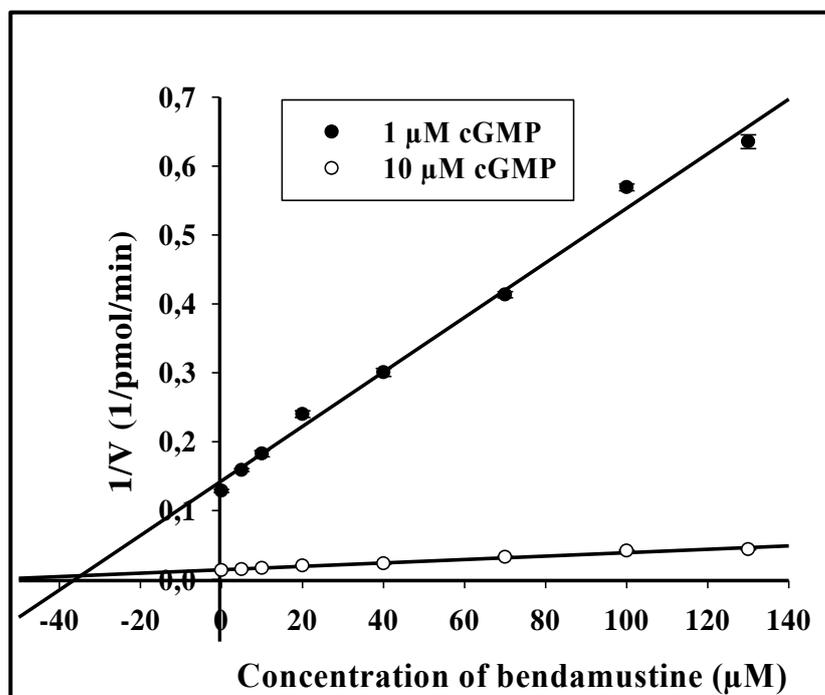

Figure 4.5 Determination of K_i value of OAT2 for bendamustine by Dixon Plot analysis. The uptake of [^3H] cyclic GMP was monitored in a buffer system containing 10 nM [^3H] cGMP and 990 nM or 9.99 μM cGMP in the presence of 0, 5 μM , 10 μM , 20 μM , 40 μM , 70 μM , 100 μM , and 130 μM bendamustine. Data are means \pm SEMs of 3 independent experiments with three repeats of each sample. Figure is representative and the K_i value was calculated from three individual experiments.

4.1.2.2 Concentration dependent inhibition of OAT2 mediated [^3H] cGMP uptake by irinotecan

The affinity of OAT2 for irinotecan was calculated from experiments wherein the uptake was measured in the presence of increasing concentrations of irinotecan in the range of 0 – 130 μM . Plots of the reciprocal of velocity of uptake on Y axis over the concentration of the antineoplastic compound on X axis revealed K_i value of OAT2 for irinotecan to be $26.4 \pm 2.34 \mu\text{M}$ (Fig. 4.6).

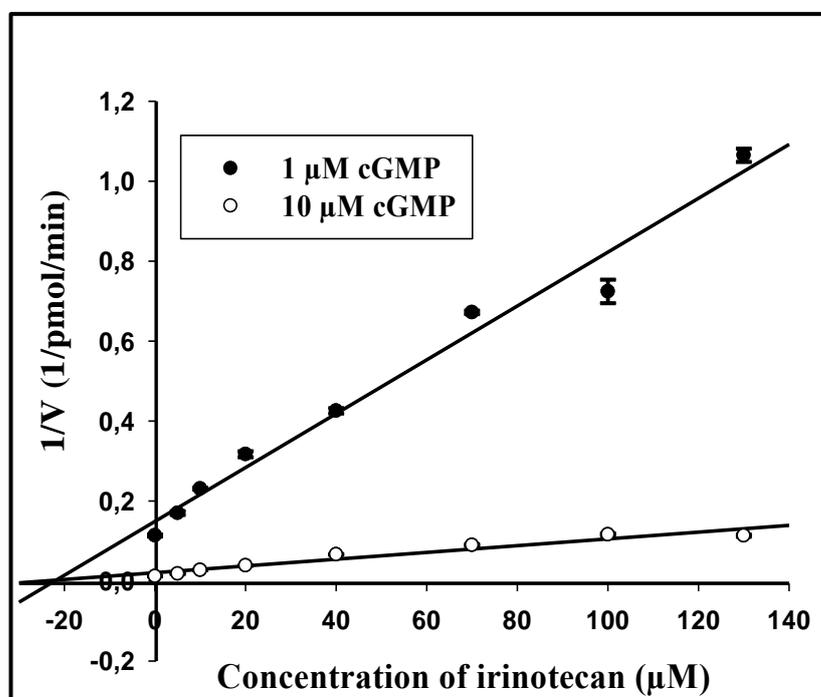

Figure 4.6 Determination of K_i value of OAT2 for irinotecan by Dixon Plot analysis.

The uptake of [^3H] cyclic GMP was monitored in a buffer system containing 10 nM [^3H] cGMP

and 990 nM or 9.99 μM cGMP in the presence of 0, 5 μM , 10 μM , 20 μM , 40 μM , 70 μM , 100 μM , and 130 μM irinotecan. Data are means \pm SEMs of 3 independent experiments with three repeats of each sample. Figure is representative and the K_i value was calculated from three individual experiments.

4.1.2.3 Concentration dependent inhibition of OAT2 mediated [^3H] cGMP uptake by paclitaxel

The affinity of OAT2 for paclitaxel was calculated from experiments wherein the uptake was measured in the presence of increasing concentrations of paclitaxel in the range of 0 – 20 μM . Plots of the reciprocal of velocity of uptake on Y axis over the concentration of the antineoplastic compound on X axis revealed K_i value of OAT2 for paclitaxel to be 10.4 ± 0.45 μM (Fig. 4.7).

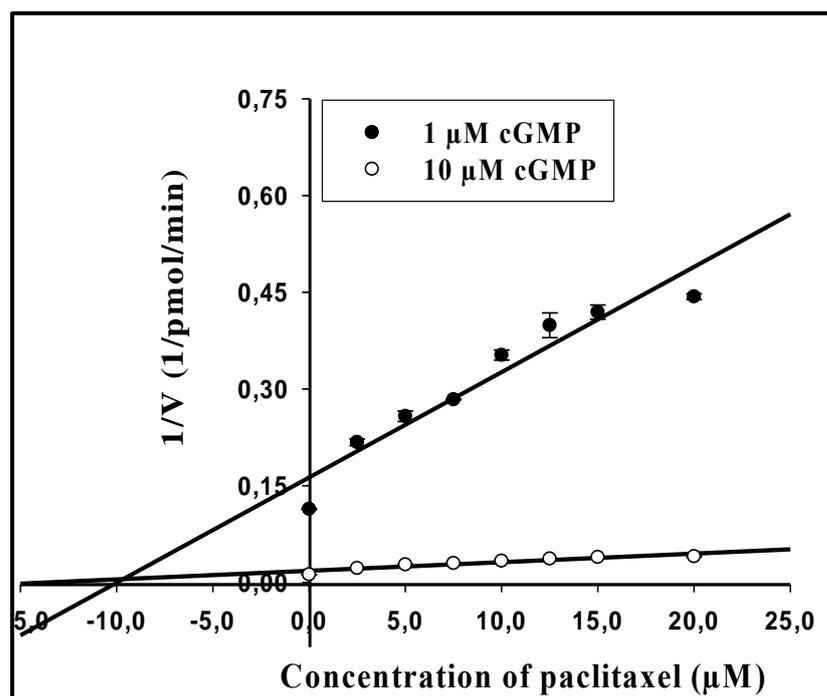

Figure 4.7 Determination of K_i value of OAT2 for paclitaxel by Dixon – Plot analysis. The uptake of [^3H] cyclic GMP was monitored in a buffer system containing 10 nM [^3H] cGMP and 990 nM or 9.99 μM cGMP in the presence of 0, 2.5 μM , 5 μM , 7.5 μM , 10 μM , 12.5 μM , 15 μM , and 20 μM paclitaxel from 0 to 20 μM . Data are means \pm SEMs of 3

independent experiments with three repeats of each sample. Figure is representative and the K_i value was calculated from three individual experiments.

4.1.3 Evaluation of OAT2 mediated uptake of bendamustine by apoptosis

To find out, indirectly, whether bendamustine is transported by OAT2, an enzymatic assay measuring the activity of caspase-3 enzyme, a key enzyme in the cascade of apoptosis, was performed. The assay is based on the ability of the caspase-3 enzyme in cell lysates to cleave the substrate bound to a fluorescent dye, releasing the fluorophore which was then estimated. Incubation of OAT2 expressing cells with 100 μM bendamustine showed an increase in the caspase-3 activity by ca. 16% of untreated pcDNA while the activity in control cells did not change significantly. This increase in caspase-3 activity was completely diminished when the bendamustine treatment was performed in combination with 100 μM probenecid, an OAT2 inhibitor (Fig. 4.8).

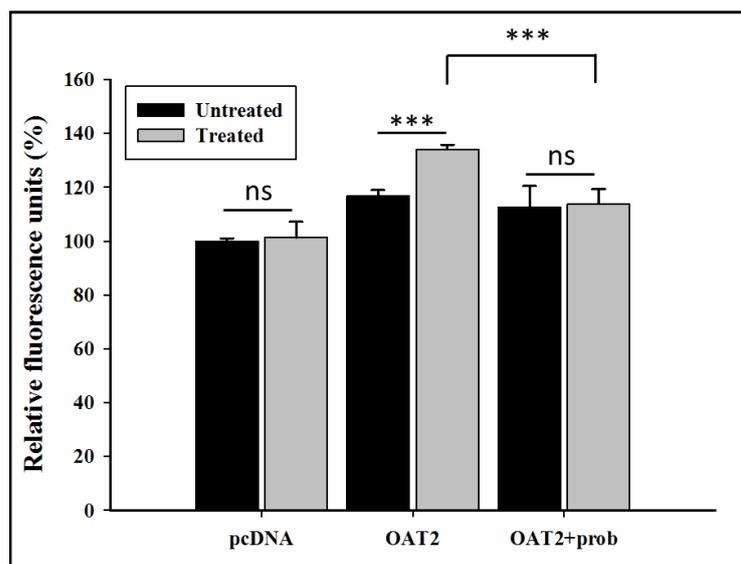

Figure 4.8 Evaluation of OAT2 mediated apoptosis. Caspase-3 activity was monitored in OAT2 expressing cells and pcDNA cells incubated with 100 μ M bendamustine for 12 h alone or in the presence of 100 μ M probenecid. The relative fluorescence unit values obtained in the experiment were normalized with protein levels and expressed as % of the value obtained in control pcDNA cells. Data are means \pm SEMs of two individual experiments with two technical repeats each. *** indicates p value $<$ 0.001; ns - not significant.

4.1.4 Evaluation of OAT2 mediated accumulation of irinotecan by HPLC analysis

The OAT2 uptake of irinotecan was determined by HPLC analysis. A working protocol was established and standardized prior to the assay. The characteristic peaks for each compound were obtained by injections of pure substances in the same conditions of the experimental run. Standard curves were plotted for both irinotecan as well as camptothecin (internal standard) in the range of 15 pmol to 500 pmol. The results from three independent runs show that the retention times of irinotecan and camptothecin were

ca. 5.7 min and 11.6 min respectively. Using them as reference in each experiment, uptake amount was quantified.

4.1.4.1 Quantitation of OAT2 mediated uptake of irinotecan

From the standard curve, the amount of irinotecan found in lysates of OAT2 expressing cells was approximately 86 pmol/ 5 min which was regarded as 100%. Accumulation of irinotecan in mock pcDNA cells was 57.4 % \pm 7.5 % of irinotecan found in OAT2 expressing cells (Fig. 4.9). The uptake of irinotecan was strongly inhibited by 100 μ M cGMP to 68.6 \pm 12.2 % in OAT2 expressing cells whereas the irinotecan uptake was not significantly changed in pcDNA treated with 100 μ M cGMP (49.7 % \pm 12.1 %) confirming the cGMP induced reduction in the accumulation of irinotecan is specific to transport by OAT2.

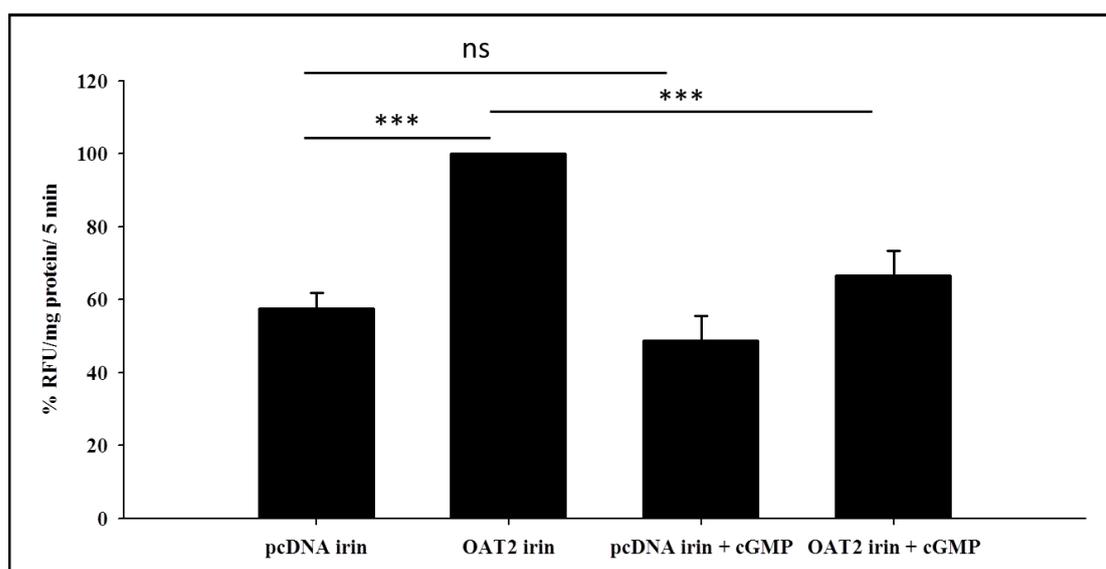

Figure 4.9 Evaluation of OAT2 mediated irinotecan uptake. Irinotecan uptake was monitored by HPLC analysis in pcDNA and OAT2 expressing cells treated with 100 μ M irinotecan alone or in combination with 100 μ M cGMP. The amount of irinotecan found was normalized with internal standard and as well to protein concentration and expressed as uptake per mg protein. Irinotecan uptake in OAT2 expressing cells treated with irinotecan alone is taken

as 100 % and the other conditions are represented as percentage of that value. Data are means \pm SEMs of three individual experiments. RFU - relative fluorescence units. *** indicates p value $<$ 0.001; ns - not significant.

4.1.4.2 Time dependent OAT2 mediated uptake of irinotecan

The amount of irinotecan in the cells was analyzed in pcDNA and OAT2 cells incubated with 100 μ M irinotecan for increasing periods of time. There was an increase both in the OAT2 dependent as well as nonspecific uptake into the cells, however, the OAT2 mediated uptake was far more pronounced as can be seen from the net uptake plotted against time (Fig.4.10).

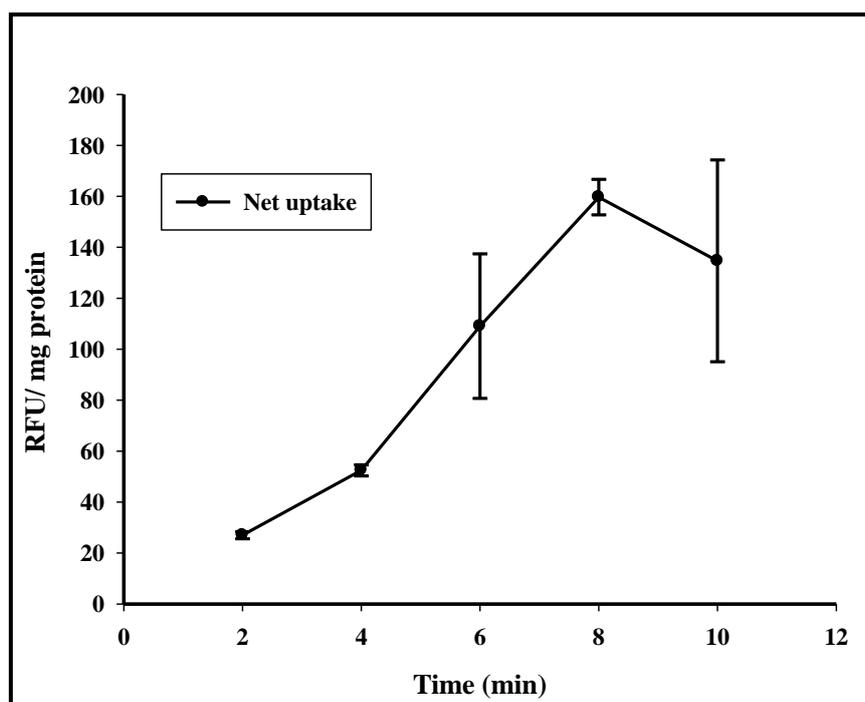

Figure 4.10 Evaluation of time dependent uptake of irinotecan. Irinotecan uptake was monitored in pcDNA and OAT2 cells after incubation with irinotecan for 2, 4, 6, 8 and 10 min. The uptake was normalized to the internal standard and the protein amount and the net uptake was calculated by subtracting the irinotecan values of pcDNA from OAT2 cells and expressed as relative fluorescence units (RFU)/ mg protein.

4.1.4.3 Concentration dependent uptake of irinotecan by pcDNA and OAT2 cells

Accumulation of irinotecan was followed by performing HPLC analyses of lysates of cells incubated with increasing amounts of irinotecan in Hank's buffer solution. Similar to time course experiments, with increase in concentration of irinotecan in the transport buffer, an increase in the amount of irinotecan was observed in the lysates. The K_m value was calculated to be $42.37 \pm 6.4 \mu\text{M}$ from two such experiments (Fig. 4.11).

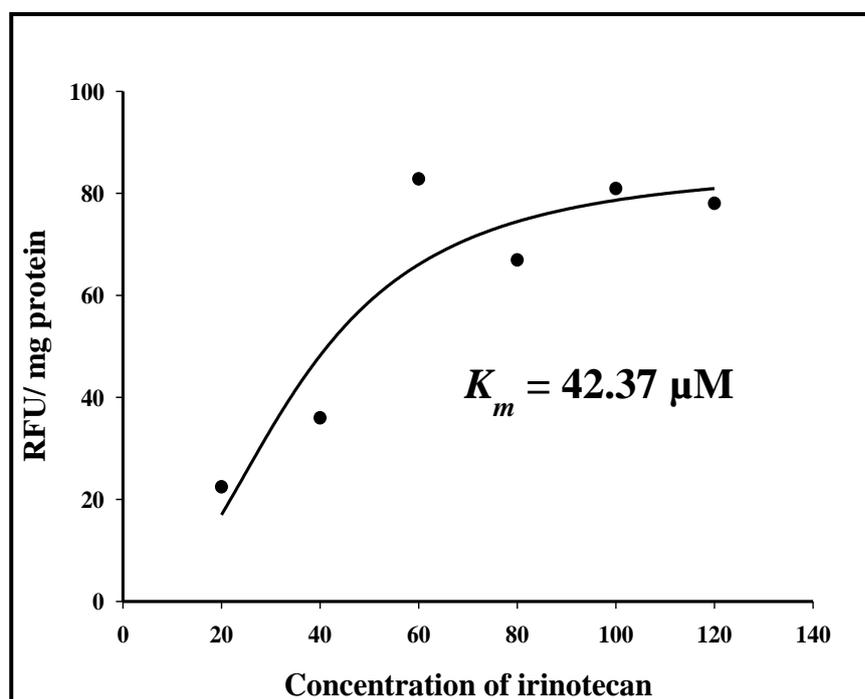

Figure 4.11 Evaluation of concentration dependent uptake of irinotecan. Irinotecan uptake was monitored in pcDNA and OAT2 cells after incubation with 20 μM , 40 μM , 60 μM , 80 μM , 100 μM , and 120 μM irinotecan for 5 min. The uptake was normalized to the internal standard and the protein amount, and the net uptake was calculated by subtracting the irinotecan values of pcDNA from OAT2 cells and expressed as relative fluorescence units (RFU)/ mg protein. Figure is representative of one of the experiments and the K_m value was calculated from two such experiments.

4.2. Interaction of sodium taurocholate cotransporting polypeptide (NTCP) with antineoplastic compounds

A functional characterization of NTCP cells stably transfected into HEK cells was performed prior to the interaction studies of NTCP with antineoplastic compounds.

4.2.1 Functional characterization of NTCP

Using estrone-3-sulfate as substrate, the transporter activity of NTCP was evaluated. Uptake experiments were performed with [³H] estrone-3-sulfate for time dependency and calculation of affinity of NTCP for estrone-3-sulfate.

4.2.1.1 Time dependent uptake of [³H] estrone -3-sulfate by NTCP expressing cells

A time course experiment was conducted with NTCP-HEK cells and vector transfected HEK cells where the uptake of 1 μ M estrone-3-sulfate was measured over a period of 30 min. From the plot, 3 min was chosen as the time for further experiments as this was in the linear phase of curve (Fig. 4.12).

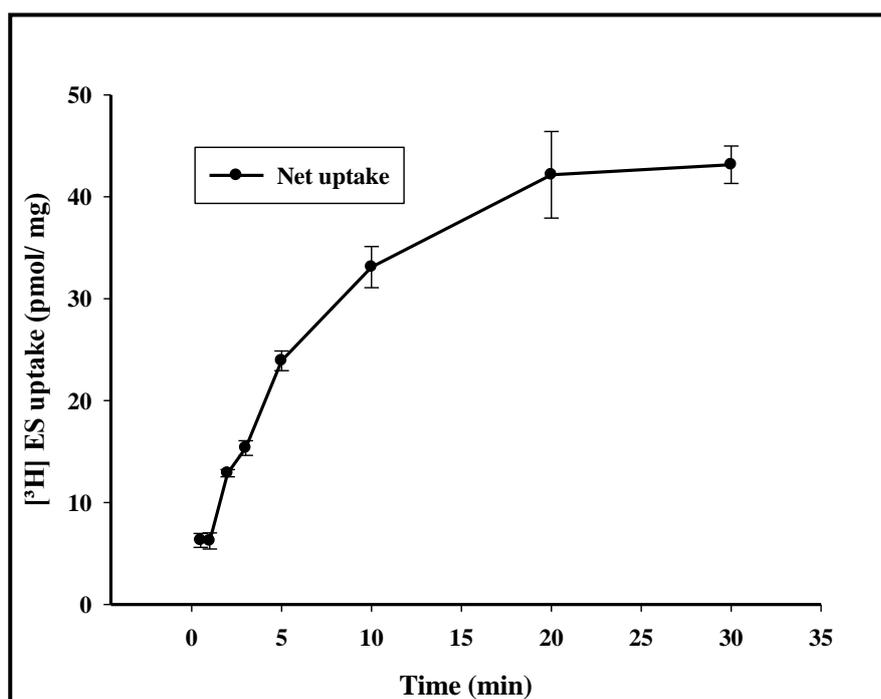

Figure 4.12 Time dependent uptake of NTCP mediated estrone-3-sulfate. The uptake of 1 μM estrone-3-sulfate containing 20 nM [^3H] estrone-3-sulfate was monitored for 0.5, 1, 2, 3, 5, 10, 20, and 30 min in NTCP expressing HEK cells and vector transfected HEK cells. Net uptake was calculated by subtracting the uptake values of control cells from NTCP expressing cells. Data is the means \pm SEMs of triplicates obtained from three identical experiments and expressed as pmol/ mg of protein.

4.2.1.2 Concentration dependent uptake of [^3H] estrone-3-sulfate by NTCP expressing cells

The affinity of NTCP for estrone-3-sulfate was determined by calculating the Michaelis-Menten constant (K_m). Uptake experiments in buffer containing 20 μM labeled [^3H] estrone-3-sulfate and increasing concentrations of unlabeled estrone sulfate for 3 min revealed the K_m value to be $217.4 \pm 12.3 \mu\text{M}$ (Fig. 4.13).

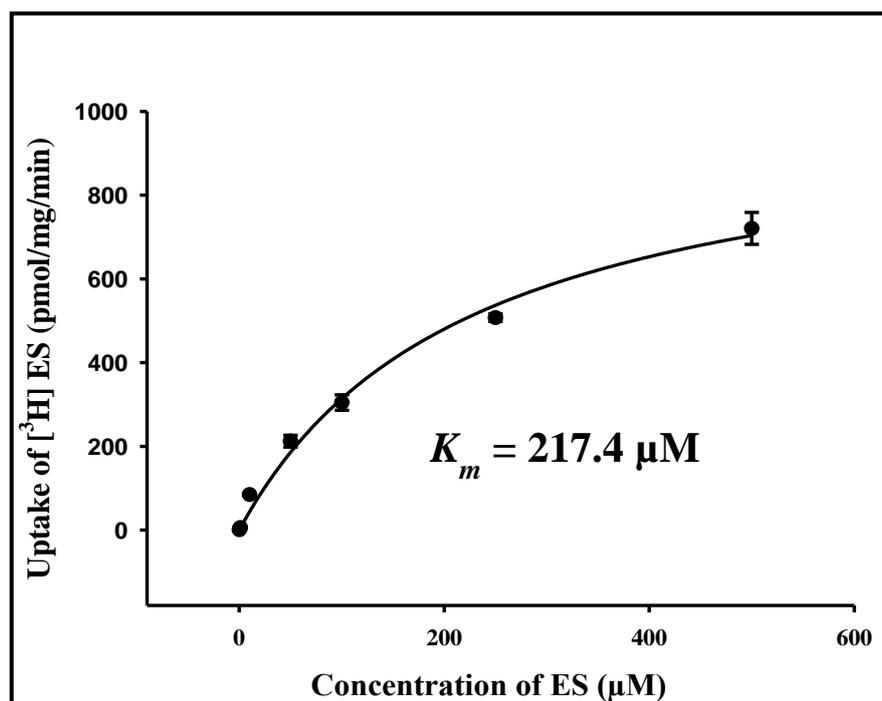

Figure 4.13 Concentration dependent uptake of estrone-3-sulfate by NTCP. The uptake of [^3H] estrone-3-sulfate was monitored in a buffer system containing 20 nM [^3H] estrone-3-sulfate and unlabeled estrone-3 sulfate amounting to a final concentration of 0.1 μM , 0.5 μM , 1

μM , 10 μM , 50 μM , 100 μM , 250 μM , and 500 μM for 3 min. Net uptake was calculated by subtracting the uptake of [^3H] estrone-3-sulfate in vector cells from the uptake in NTCP-HEK cells. Data are represented as means \pm SEMs of triplicates. The K_m value was calculated from three such experiments. The data is expressed as pmol/min/mg of protein.

4.2.2 Inhibition of NTCP mediated estrone-3-sulfate uptake by antineoplastic compounds

The uptake of [^3H] estrone-3-sulfate was measured in the presence of 100 μM of antineoplastic compounds for 3 min. Uptake values are represented as % of the uptake of substrates in the absence of any antineoplastic compound (buffer control) which was determined for NTCP to be 212.2 ± 6.2 pmol estrone-3-sulfate/ 3 min. Only a few significant changes in the uptake of [^3H] labeled estrone-3-sulfate by antineoplastic drugs were observed compared to buffer control.

4.2.2.1 Inhibition of NTCP mediated estrone-3-sulfate uptake by alkylating agents

The alkylating agents, chlorambucil and busulfan reduced significantly the uptake of estrone-3-sulfate by 27.8 ± 2.5 % and 10.2 ± 1.8 %, respectively, whereas an increase in the uptake was observed with bendamustine by 20.9 ± 3.9 % of buffer control. No significant interactions were observed with the other alkylating agents melphalan, cyclophosphamide, trofosfamide, ifosfamide, treosulfan, and thioTEPA (Fig. 4.14).

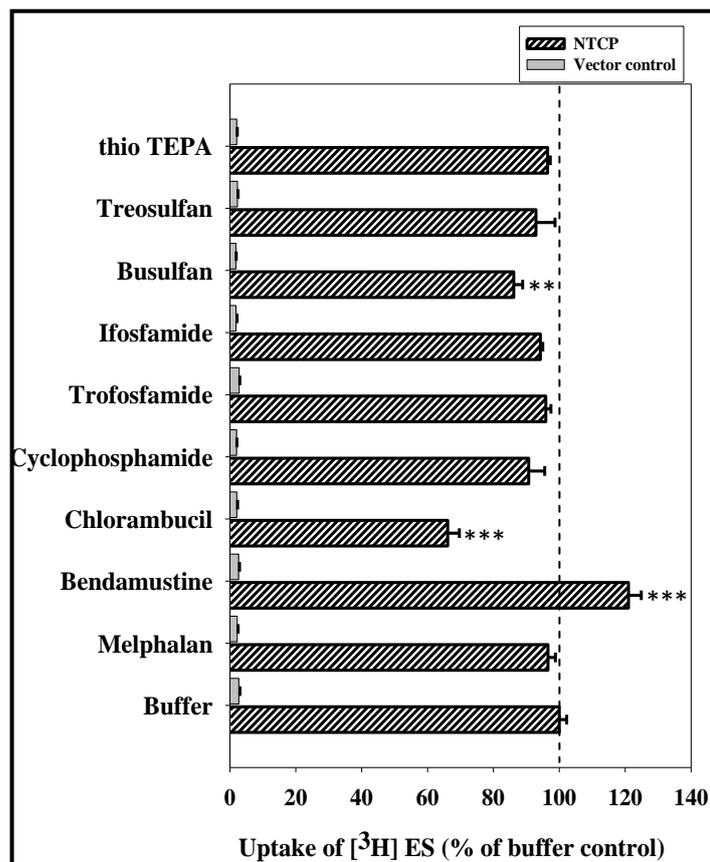

Figure 4.14. Interaction of NTCP with alkylating agents. The uptake of [^3H] estrone-3-sulfate was monitored in a buffer system containing 20 nM [^3H] estrone-3-sulfate and 19.98 μM estrone-3-sulfate in the presence or absence of 100 μM of the respective alkylating compound in NTCP transfected HEK cells and vector transfected HEK cells. Data are means \pm SEMs of three individual experiments with three repeats each. ** represents p value < 0.01 , *** represents p value < 0.001 .

4.2.2.2 Inhibition of NTCP mediated estrone-3-sulfate uptake by antimetabolites

None of the antimetabolites tested were able to cause any significant interaction in the uptake of NTCP mediated [^3H] estrone-3-sulfate (Fig. 4.15).

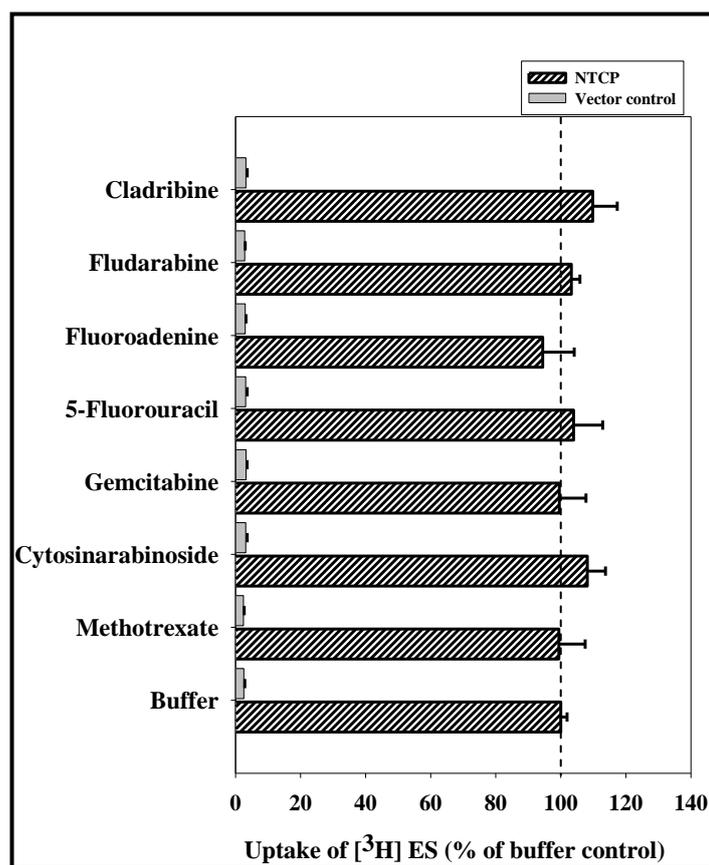

Figure 4.15. Interaction of NTCP with antimetabolites. The uptake of [³H] estrone-3-sulfate was monitored in a buffer system containing 20 nM [³H] estrone-3-sulfate and 19.98 μM estrone-3-sulfate in the presence or absence of 100 μM of the respective antimetabolite in NTCP transfected HEK cells and vector transfected HEK cells. Data are means ± SEMs of three individual experiments with three repeats each.

4.2.2.3 Inhibition of NTCP mediated estrone-3-sulfate uptake by intercalating agents and mitotic inhibitors

Among the intercalating agents, mitoxantrone significantly reduced the uptake of NTCP mediated estrone-3-sulfate by 10.6 ± 2.4 % whereas doxorubicin did not alter the uptake. Among the mitotic inhibitors, vincristine and paclitaxel caused an inhibition of uptake by 13.7 ± 3 % and 53.3 ± 1.9 % of buffer control, respectively. The other mitotic inhibitor tested, vinblastine, did not cause any significant change in the uptake (Fig. 4.16).

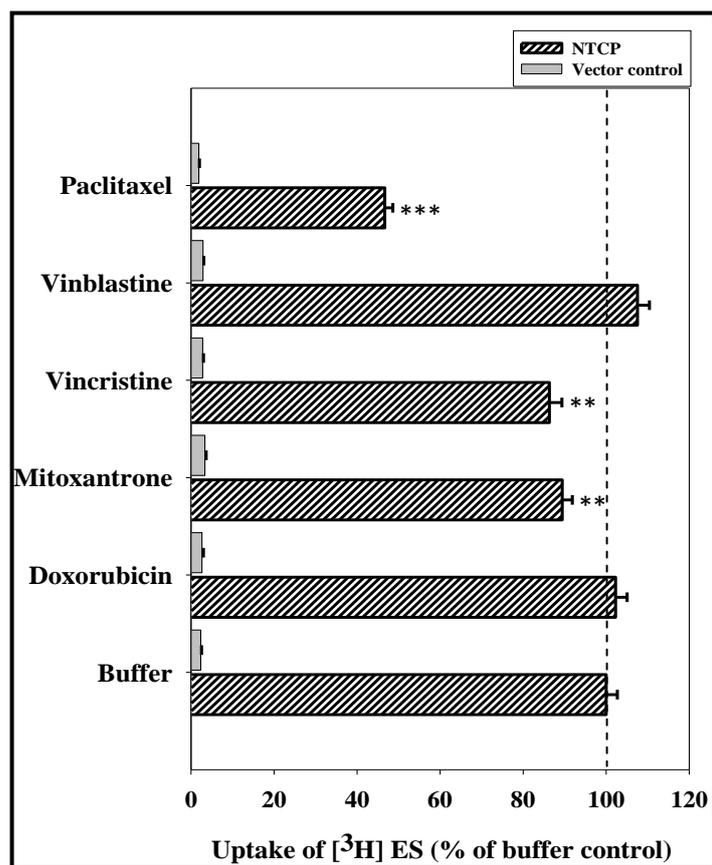

Figure 4.16. Interaction of NTCP with intercalating agents and mitotic inhibitors.

The uptake of [^3H] estrone-3-sulfate was monitored in a buffer system containing 20 nM [^3H] estrone-3-sulfate and 19.98 μM estrone-3-sulfate in the presence or absence of 100 μM of the respective compound in NTCP transfected HEK cells and vector transfected HEK cells. Data are means \pm SEMs of three individual experiments with three repeats each. ** represents p value < 0.01, *** represents p value < 0.001.

4.2.2.4 Inhibition of NTCP mediated estrone-3-sulfate uptake by topoisomerase inhibitors and compounds targeting hormone receptors

None of the topoisomerase inhibitors or the antineoplastic drugs targeting hormone receptors caused any significant interaction to the uptake of estrone-3-sulfate by NTCP-HEK cells (Fig. 4.17).

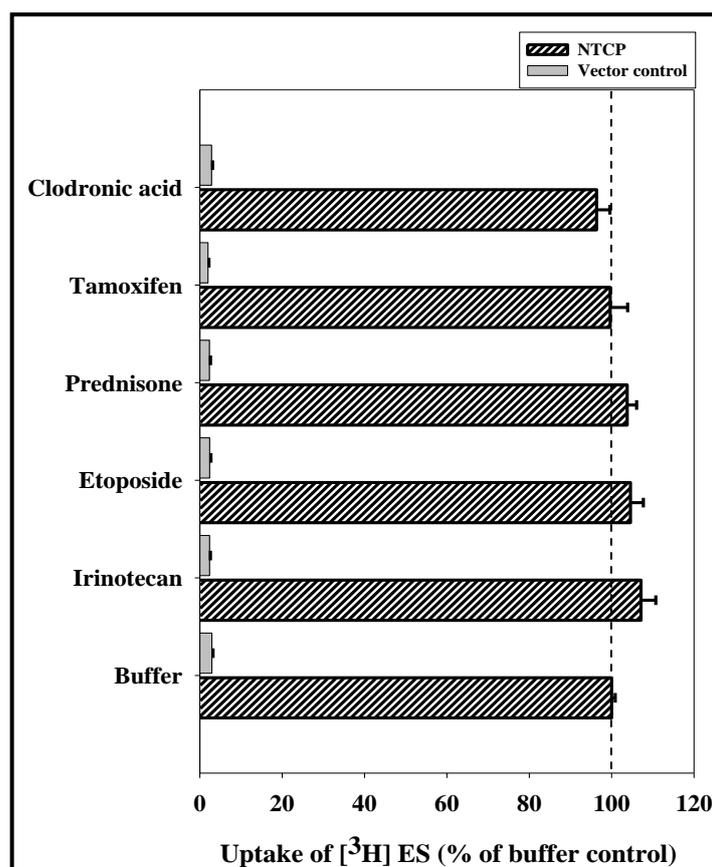

Figure 4.17. Interaction of NTCP with topoisomerase inhibitors and hormone receptor targeters. The uptake of [³H] estrone-3-sulfate was monitored in a buffer system containing 20 nM [³H] estrone-3-sulfate and 19.98 μ M estrone-3-sulfate in the presence or absence of 100 μ M of the respective compound in NTCP transfected HEK cells and vector transfected HEK cells. Data are means \pm SEMs of three individual experiments with three repeats each.

4.3. Interaction of organic anion transporting polypeptide 1B1 (OATP1B1) with antineoplastic compounds

Functionally characterized HEK cells stably expressing OATP1B1 were obtained from Dr. Saskia Flörl, PortaCellTec GmbH. Estrone-3-sulfate was used as the substrate for the study of transporter activity of OATP1B1. From initial experiments, 5 min was chosen as the time of uptake for further experiments and the K_m value was calculated to be 0.23 μM . So, the inhibition studies were performed with the uptake time of 5 min and the substrate concentration of 0.23 μM .

4.3.1 Inhibition of OATP1B1 mediated estrone sulfate uptake by antineoplastic agents

The uptake of [^3H] estrone-3-sulfate was monitored in the presence of 100 μM antineoplastic compounds in OATP1B1 expressing cells and vector transfected cells. Uptake values are represented as % of the uptake of substrates in the absence of any antineoplastic compound which was determined for OATP1B1 to be 118.2 ± 6.5 pmol estrone 3- sulfate/ 5 min. The absolute uptake value without drugs in each individual experiment was regarded as 100% and uptake under all other conditions is represented as percentage of this value. Significant changes were observed in the interaction studies with many of the antineoplastic compounds.

4.3.1.1 Inhibition of OATP1B1 mediated estrone-3-sulfate uptake by alkylating agents

Among the alkylating agents, a weak but significant stimulation of OATP1B1 mediated uptake of [^3H] estrone-3-sulfate was observed in cells incubated with chlorambucil by 18.8 ± 2.4 %, cyclophosphamide by 5.6 ± 0.98 %, trofosfamide by 13.1 ± 1.2 %,

ifosfamide by $7.4 \pm 1.9 \%$ and thio TEPA by $11.9 \pm 0.59 \%$. Any inhibitory effect of alkylating agents on OATP1B1 mediated uptake was not observed (Fig. 4.18)

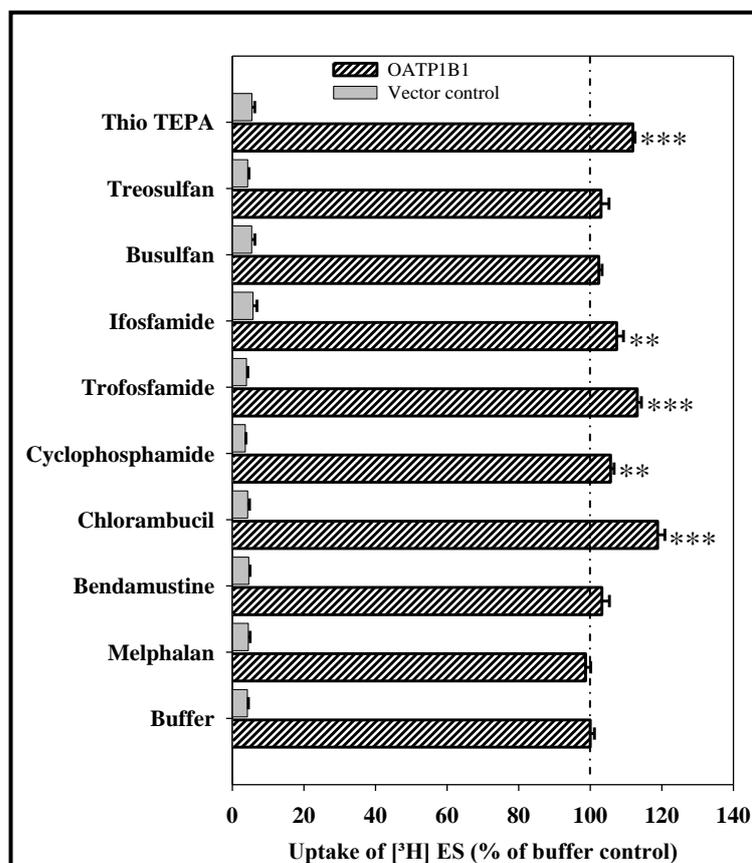

Figure 4.18 Inhibition of OATP1B1 mediated estrone-3-sulfate uptake by alkylating agents. The uptake of $[^3\text{H}]$ estrone-3-sulfate was followed in the presence of $100 \mu\text{M}$ of alkylating agents. Data is represented as percentage of uptake observed in the absence of any compounds and are means \pm SEM of three individual experiments with three repeats each. * represents p value < 0.05 ** represents p value < 0.01 , *** represents p value < 0.001 .

4.3.1.2 Inhibition of OATP1B1 mediated estrone-3-sulfate uptake by antimetabolites

Among antimetabolites, cladribine alone caused a significant change in the uptake of estrone-3-sulfate by OATP1B1; it stimulated the uptake by $15.9 \pm 3.8 \%$ of buffer

control. None of the remaining antimetabolites caused any effect on the OATP1B1 mediated uptake (Fig. 4.19).

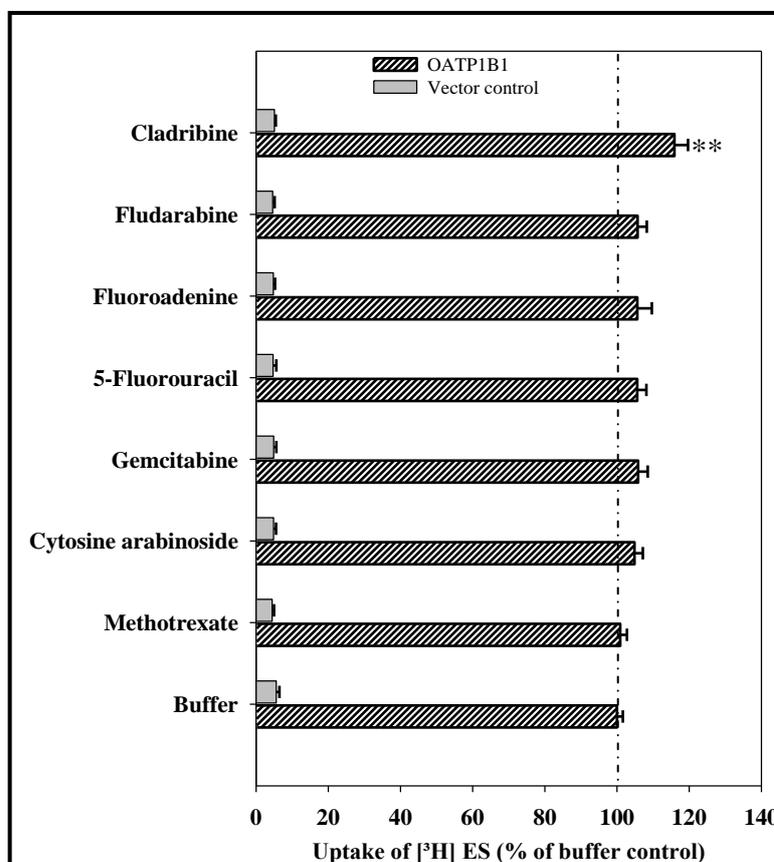

Figure 4.19 Inhibition of OATP1B1 mediated estrone-3-sulfate uptake by antimetabolites. The uptake of $[^3\text{H}]$ estrone-3-sulfate was followed in the presence of $100\ \mu\text{M}$ of antimetabolites. Data is represented as percentage of uptake observed in the absence of any compounds and are means \pm SEM of three individual experiments with three repeats each. ** represents p value < 0.01 .

4.3.1.3 Inhibition of OATP1B1 mediated estrone-3-sulfate uptake by intercalating agents and mitotic inhibitors

The intercalating agents, doxorubicin and mitoxantrone, and the mitotic inhibitor vincristine significantly reduced the OATP1B1-mediated uptake of estrone 3- sulfate by $12 \pm 2.2\%$, $18.9 \pm 2.0\%$, and $28.1 \pm 1.4\%$ of buffer control, respectively. The uptake

was strongly reduced in the presence of the other mitotic inhibitors vinblastine and paclitaxel by $64.1 \pm 1.5 \%$ and $87.6 \pm 0.5 \%$, respectively (Fig. 4.20).

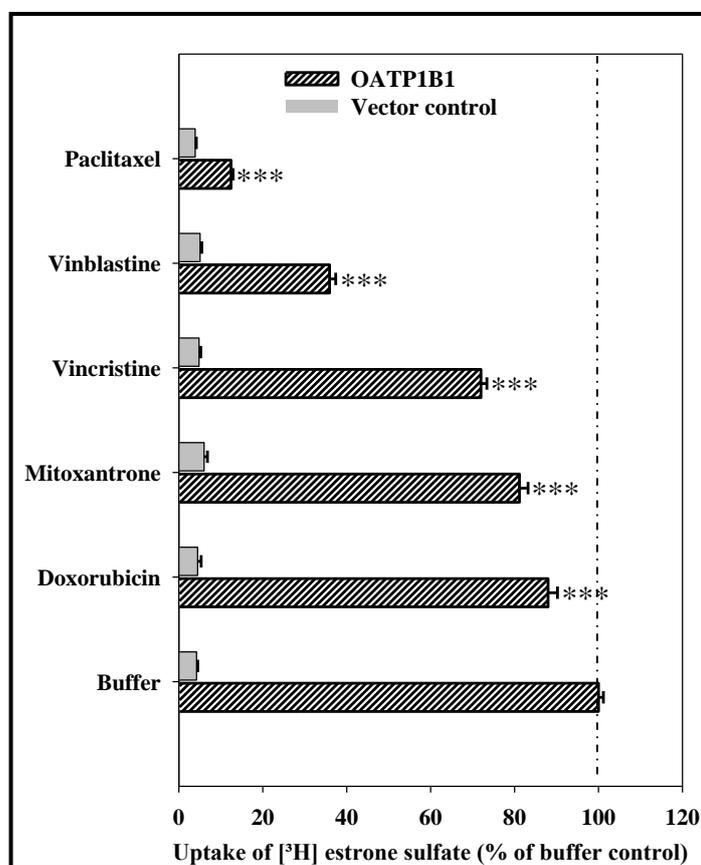

Figure 4.20 Inhibition of OATP1B1 mediated estrone-3-sulfate uptake by intercalating agents and mitotic inhibitors. The uptake of [^3H] estrone-3-sulfate was followed in the presence of $100 \mu\text{M}$ of intercalating agents and mitotic inhibitors. Data is represented as percentage of uptake observed in the absence of any compounds and are means \pm SEM of three individual experiments with three repeats each. * represents p value < 0.05 , *** represents p value < 0.001 .

4.3.1.4 Inhibition of OATP1B1 mediated estrone-3-sulfate uptake by topoisomerase inhibitors and hormone receptor targets

Among the topoisomerase inhibitors, irinotecan caused a profound stimulation of the uptake of [^3H] estrone-3-sulfate by $93.3 \pm 5.0 \%$ of buffer control while incubation with

the compounds prednisone and tamoxifen resulted in a decrease of the uptake by $9.8 \pm 2.7\%$ and $16.4 \pm 3.1\%$ of buffer control, respectively (Fig. 4.21). Etoposide and clodronic acid did not cause any significant changes in the uptake.

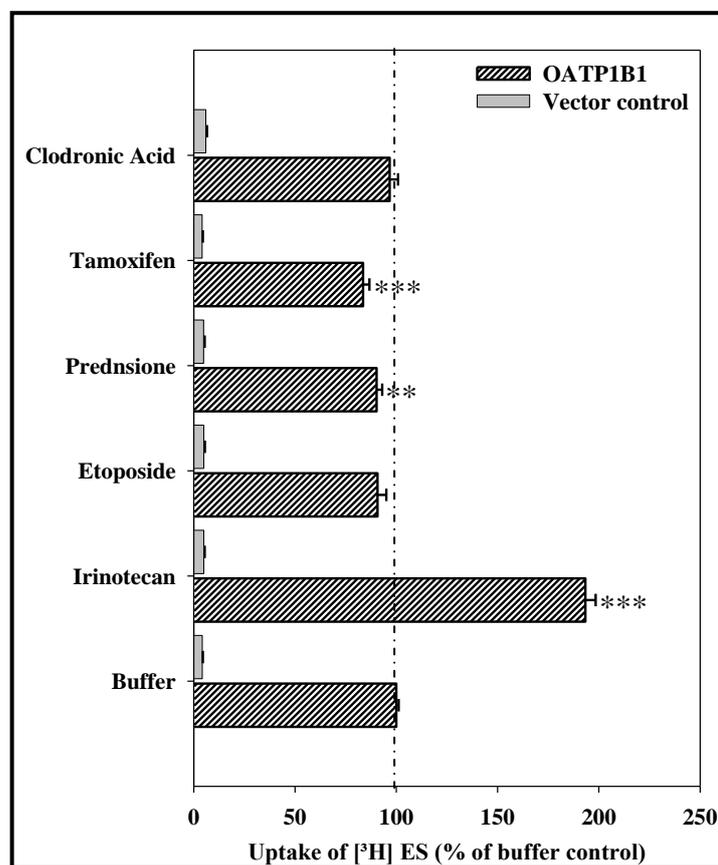

Figure 4.21 Inhibition of OATP1B1 mediated estrone-3-sulfate uptake by topoisomerase inhibitors and hormone receptor targeters. The uptake of $[^3\text{H}]$ estrone-3-sulfate was followed in the presence of $100\ \mu\text{M}$ of topoisomerase inhibitors and hormone receptor targeters. Data is represented as percentage of uptake observed in the absence of any compounds and are means \pm SEM of three individual experiments with three repeats each. ** represents p value < 0.01 , *** represents p value < 0.001 .

4.3.2 Concentration dependent inhibition of antineoplastic compounds on OATP1B1 mediated estrone-3-sulfate uptake

As the two compounds, vinblastine and paclitaxel, strongly inhibited the uptake of OATP1B1 mediated estrone sulfate uptake to less than 40 % of buffer control, the kinetic constants of inhibition of OATP1B1 were determined for these compounds.

4.3.2.1 Concentration dependent inhibition of vinblastine on OATP1B1 mediated estrone-3-sulfate uptake

Dixon plot analysis of the uptake of [³H] estrone-3-sulfate in buffer solutions containing 0.25 μ M or 2.5 μ M estrone-3-sulfate in the presence of increasing concentrations of vinblastine revealed the K_i value of OATP1B1 for vinblastine to be $10.2 \mu\text{M} \pm 0.18 \mu\text{M}$.

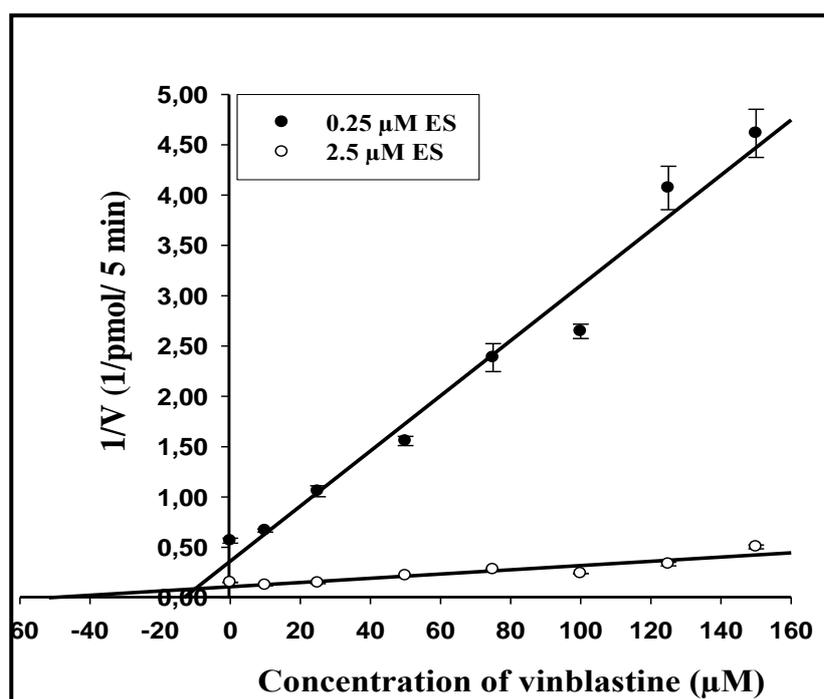

Figure 4.22 Concentration dependent inhibition of OATP1B1-mediated estrone-3-sulfate by vinblastine. The uptake of [³H] estrone-3-sulfate was measured in the presence of 0, 10 μ M, 25 μ M, 50 μ M, 75 μ M, 100 μ M, 125 μ M, and 150 μ M vinblastine. Dark circles represent the uptake values at 0.25 μ M estrone-3-sulfate and clear circles represent uptake at 2.5 μ M

estrone-3-sulfate. Figure is representative and K_i value was calculated from two such experiments. Data are means \pm SEMs of two independent experiments with three repeats each.

4.3.2.2 Concentration dependent inhibition of paclitaxel on OATP1B1 mediated estrone-3-sulfate uptake

Dixon plot analysis of the uptake of [^3H] estrone-3-sulfate in solutions containing 0.25 μM or 2.5 μM estrone-3-sulfate in the presence of increasing concentrations of paclitaxel revealed the K_i value of OATP1B1 for paclitaxel to be $0.84 \mu\text{M} \pm 0.10 \mu\text{M}$.

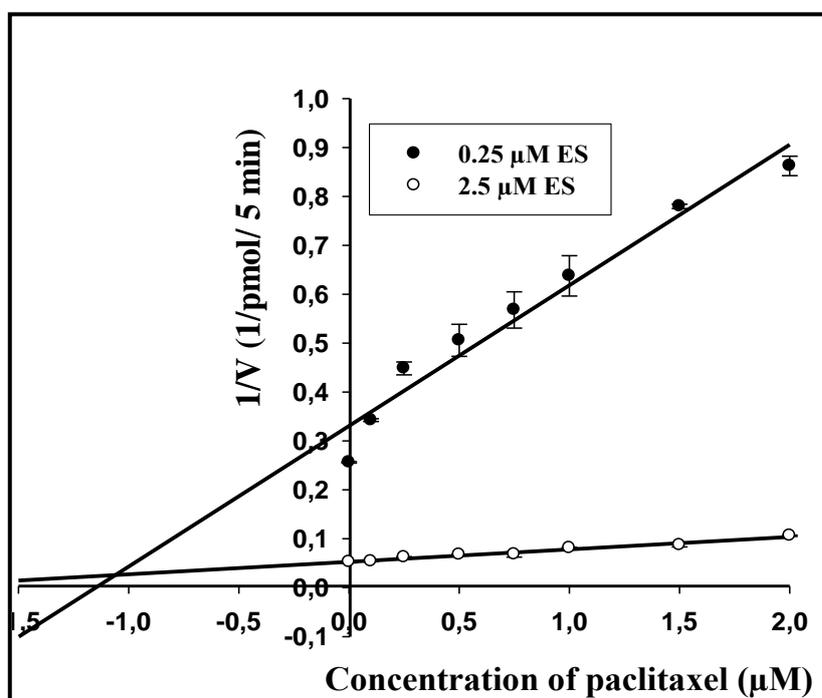

Figure 4.23 Concentration dependent inhibition of OATP1B1-mediated estrone-3-sulfate by paclitaxel. The uptake of [^3H] estrone-3-sulfate was measured in the presence of 0, 0.1 μM , 0.25 μM , 0.5 μM , 0.75 μM , 1 μM , 1.5 μM , and 2 μM of paclitaxel. Dark circles represent the uptake values at 0.25 μM estrone-3-sulfate and clear circles represent uptake at 2.5 μM estrone-3-sulfate. Figure is representative and K_i value was calculated from two such experiments. Data are means \pm SEMs of two independent experiments with three repeats each.

4.4. Interaction of organic anion transporting polypeptide 1B3 (OATP1B3) with antineoplastic compounds

To study the interactions between the antineoplastic compounds and OATP1B3, initial functional characterization was performed with human embryonic kidney cells expressing OATP1B3 as a system to measure the transport activity.

4.4.1 Functional characterization of OATP1B3 transporter activity

Initial functional characterization of OATP1B3 protein involved time dependent and concentration dependent uptake of the radiolabeled substrate cholecystinin octapeptide ($[^3\text{H}]$ CCK-8).

4.4.1.1 Time dependent uptake of $[^3\text{H}]$ CCK-8 by OATP1B3 expressing cells

A time course experiment was performed with OATP1B3 expressing HEK cells and vector transfected HEK cells wherein the uptake of $[^3\text{H}]$ CCK-8 was measured over a range of 30 min. From the time course experiments, 2 min was selected for further experiments as this was in the linear range of uptake (Fig.4.24).

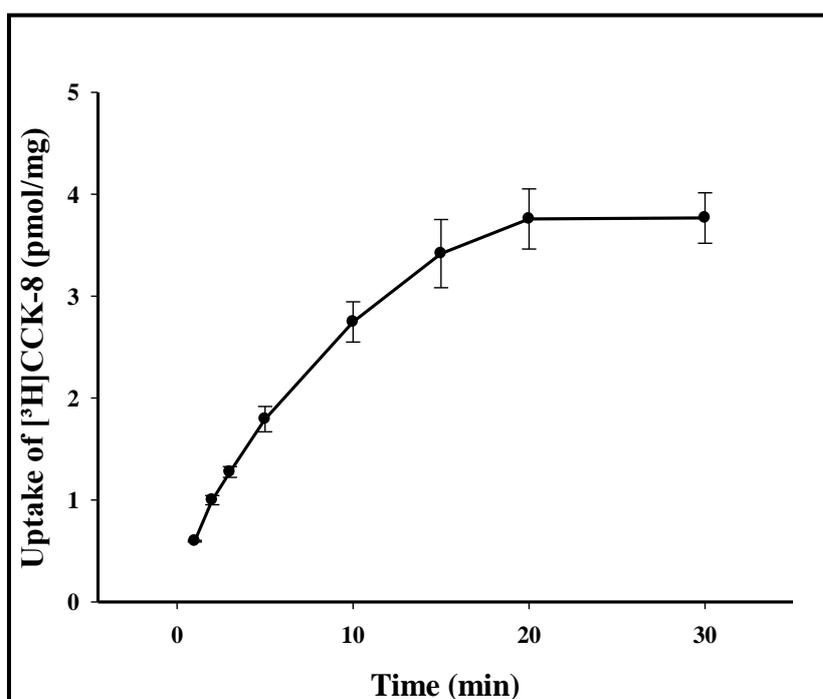

Figure 4.24. Time dependent uptake of OATP1B3. Uptake of [³H] CCK-8 was measured in buffer containing 5 nM [³H] CCK-8 and 245 nM CCK-8 for 1, 2, 3, 5, 10, 15, 20, and 30 min. The net uptake was calculated by subtracting the uptake in vector cells from the uptake in OATP1B3 expressing cells and plotted against time. Data are means \pm SEMs of three independent experiments with three repeats each.

4.4.1.2 Concentration dependent uptake of [³H] CCK-8 by OATP1B3 expressing cells

The affinity of OATP1B3 was determined by calculating the Michaelis-Menten constant K_m for the interaction. Measurement of uptake of [³H] CCK-8 in the presence of increasing concentrations of unlabeled CCK-8 for 2 min revealed a K_m of OATP1B3 for CCK-8 to be $13.2 \pm 1.6 \mu\text{M}$ (Fig. 4.25).

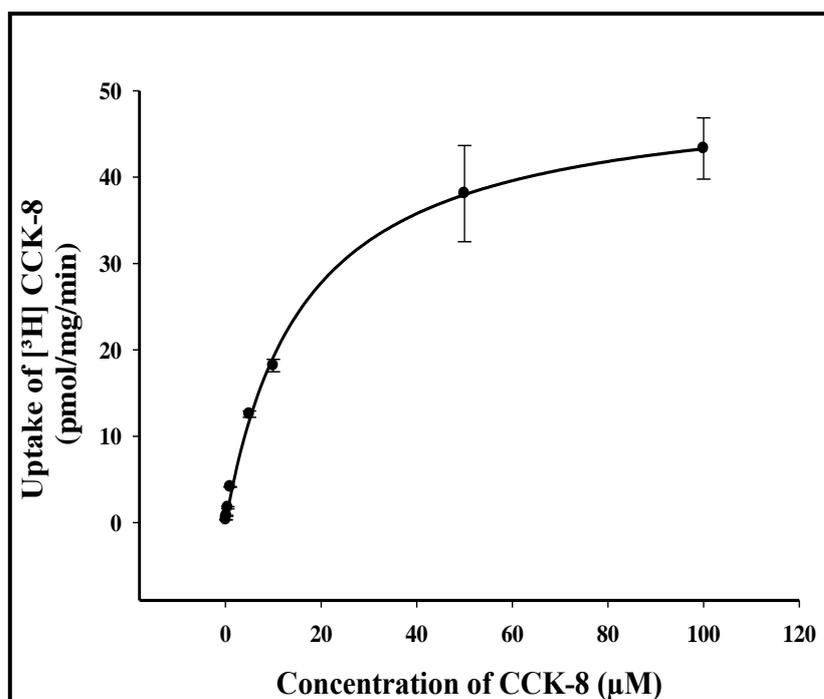

Figure 4.25. Concentration dependent uptake of OATP1B3. Uptake of [³H] CCK-8 was measured in buffer solution containing 5 nM [³H] CCK-8 mixed with unlabeled CCK-8 to a final concentration of 0.1 µM, 0.25 µM, 0.5 µM, 1 µM, 5 µM, 10 µM, 50 µM and 100 µM for 2 min. The net uptake was calculated by subtracting the uptake in vector cells from the uptake in OATP1B3 expressing cells and plotted against concentration of CCK-8. Data are means ± SEM of three independent experiments with three repeats each.

4.4.2 Inhibition of OATP1B3-mediated CCK-8 uptake by antineoplastic compounds

The uptake of [³H] CCK-8 was measured in the presence of 100 µM of the corresponding antineoplastic compounds in buffer solutions containing 5 nM [³H] CCK-8 mixed with 995 nM of unlabeled CCK-8 for 2 min. Uptake of [³H] CCK-8 by OATP1B3 in the absence of any of the compounds (buffer control) was calculated to be 2.9 ± 0.2 pmol CCK-8 / 2 min and the uptake in the presence of any of the antineoplastic compound tested is represented as percentage of this value. The uptake was significantly altered in the presence of a variety of compounds.

4.4.2.1 Inhibition of OATP1B3 mediated CCK-8 uptake by alkylating agents

The alkylating agents, bendamustine and chlorambucil significantly reduced the uptake by $48.8 \pm 2.5\%$ and $66 \pm 1.5\%$, respectively, whereas a slight increase in the uptake was observed with cyclophosphamide by $8.7 \pm 2.0\%$ of buffer control. There were no significant changes observed in the presence of the rest of the alkylating compounds tested (Fig. 4.26).

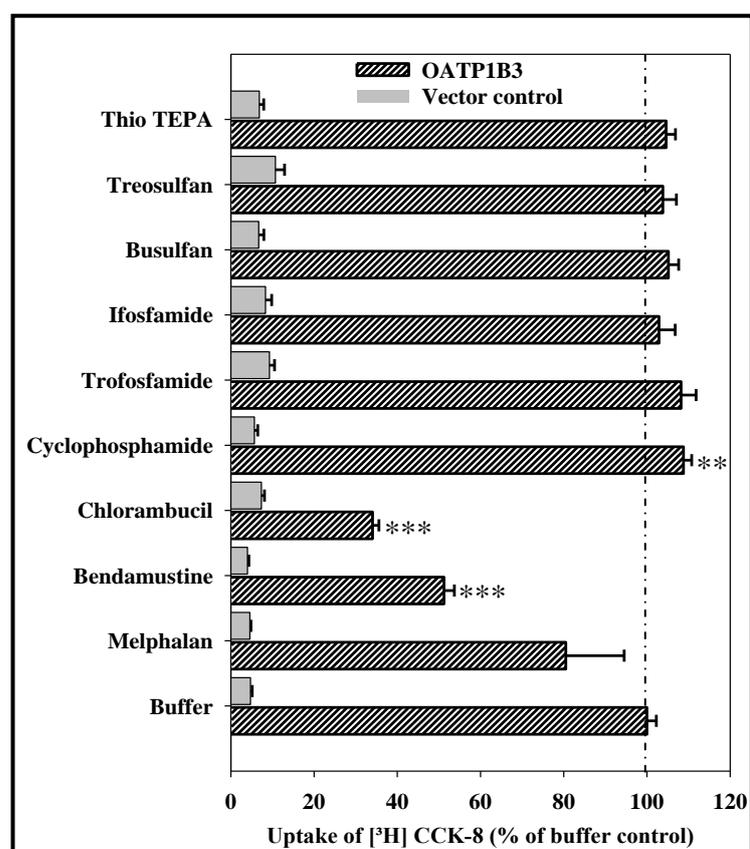

Figure 4.26 Inhibition of OATP1B3 mediated CCK-8 uptake by alkylating agents.

The uptake of $[^3\text{H}]$ CCK-8 was followed in the presence of $100\ \mu\text{M}$ of alkylating agents. Data is represented as percentages of uptake (\pm SEM) observed in the absence of any compound and are means of three individual experiments with three repeats each. ** represents p value < 0.01 , *** represents p value < 0.001 .

4.4.2.2 Inhibition of OATP1B3 mediated CCK-8 uptake by antimetabolites

Among antimetabolites, methotrexate, cytosine arabinoside, gemcitabine, fludarabine, and cladribine showed a weak stimulation of the [^3H] CCK-8 uptake by $12.0 \pm 2.12\%$, $17.7 \pm 5.9\%$, $11.1 \pm 4.6\%$, $12.0 \pm 4.2\%$, and $10.0 \pm 1.8\%$, respectively (Fig. 4.27).

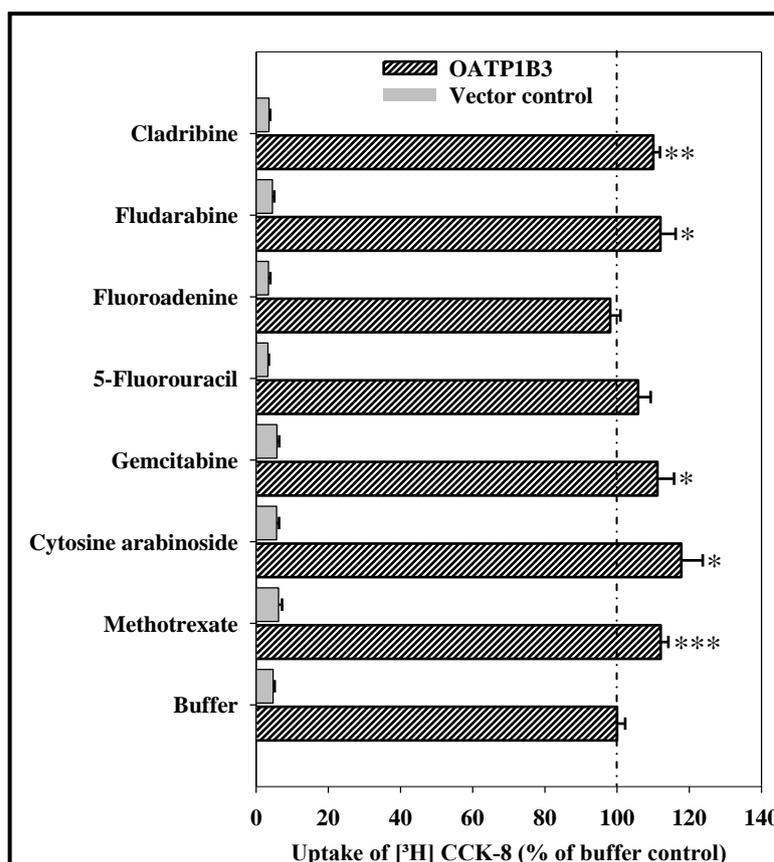

Figure 4.27 Inhibition of OATP1B3 mediated CCK-8 uptake by antimetabolites. The uptake of [^3H] CCK-8 was followed in the presence of $100\ \mu\text{M}$ of antimetabolites. Data is represented as percentage of uptake observed in the absence of any compounds and are means \pm SEM of three individual experiments with three repeats each. * represents p value < 0.05 , ** represents p value < 0.01 and *** represents p value < 0.001 .

4.4.2.3 Inhibition of OATP1B3 mediated CCK-8 uptake by intercalating agents and mitotic inhibitors

The intercalating agents, doxorubicin and mitoxantrone reduced the OATP1B3-mediated [³H] CCK-8 uptake by 53.6 ± 1.6 % and 84.4 ± 1.4 % of buffer control, respectively. Similarly, the mitotic inhibitors, vincristine, vinblastine and paclitaxel reduced the uptake by 65.1 ± 2.9 %, 81.5 ± 0.9 %, and 94.4 ± 0.5 %, respectively (Fig. 4.28).

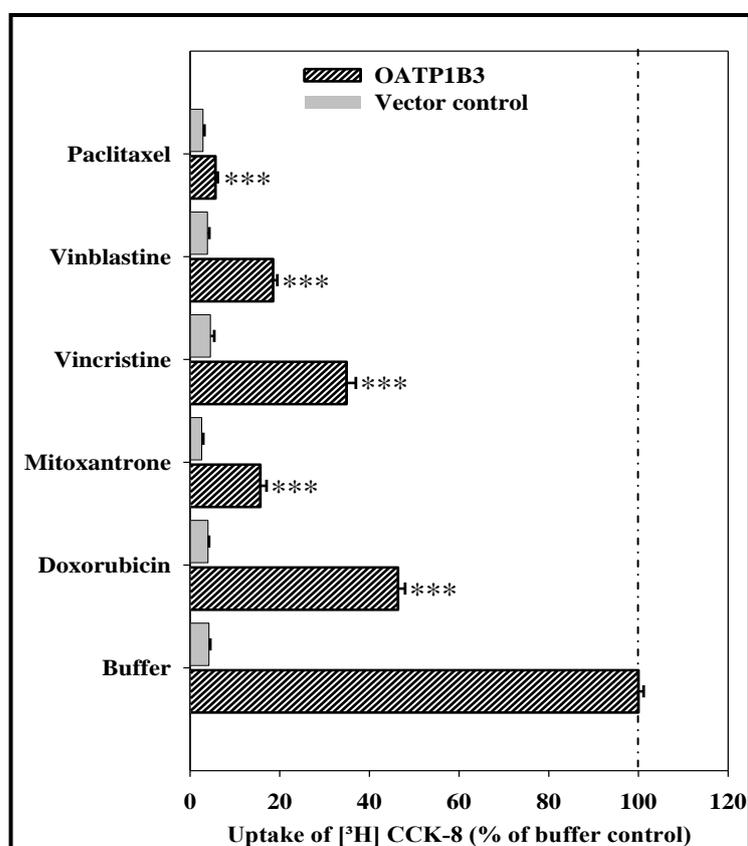

Figure 4.28 Inhibition of OATP1B3 mediated CCK-8 uptake by intercalating agents and mitotic inhibitors. The uptake of [³H] CCK-8 was followed in the presence of 100 μ M of intercalating agents and mitotic inhibitors. Data is represented as percentage of uptake observed in the absence of any compounds and are means \pm SEM of three individual experiments with three repeats each. ** represents p value < 0.01 and *** represents p value < 0.001 .

4.4.2.4 Inhibition of OATP1B3 mediated CCK-8 uptake by topoisomerase inhibitors and hormone receptor targeters

The topoisomerase inhibitors irinotecan and etoposide reduced [³H] CCK-8 uptake by $34.3 \pm 3.9 \%$ and $76.3 \pm 1.6 \%$, respectively. The uptake of [³H] CCK-8 was reduced by $12.5 \pm 4.4 \%$ in the presence of prednisone and by $38.1 \pm 3.9 \%$ in the presence of tamoxifen, respectively (Fig. 4.29).

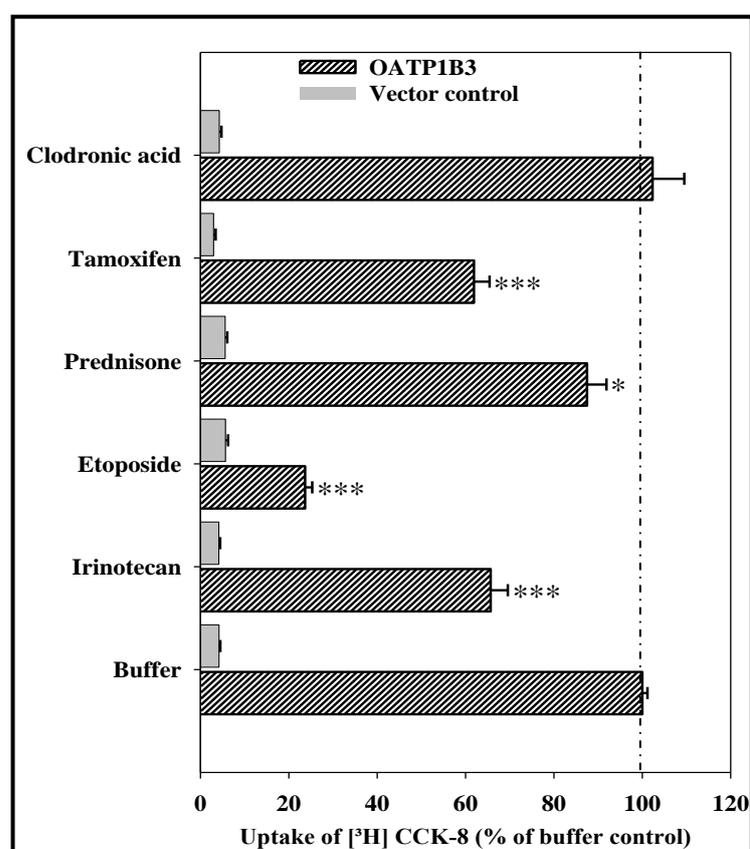

Figure 4.29 Inhibition of OATP1B3 mediated CCK-8 uptake by topoisomerase inhibitors and hormone receptor targeters. The uptake of [³H] CCK-8 was followed in the presence of 100 μM of topoisomerase inhibitors and compounds targeting hormone receptors. Data is represented as percentage of uptake observed in the absence of any compounds and are means \pm SEM of three individual experiments with three repeats each. * represents p value < 0.05 , ** represents p value < 0.01 and *** represents p value < 0.001 .

4.4.3 Concentration dependent inhibition of antineoplastic compounds on OATP1B3 mediated cholecystinin octapeptide uptake

From the inhibition experiments, it was observed that chlorambucil, mitoxantrone, vinblastine, vincristine, paclitaxel and etoposide inhibited the uptake of OATP1B3-mediated [^3H] CCK-8 uptake to less than 40% of buffer control. So, these cytostatics were analyzed further for their inhibition potency by Dixon plot analysis to elucidate the affinity of OATP1B3 for them.

4.4.3.1 Concentration dependent inhibition of chlorambucil on OATP1B3 mediated CCK-8 uptake

Measurement of the uptake of [^3H] CCK-8 at two different substrate concentrations in the presence of increasing concentration of chlorambucil revealed the K_i value to be $37.4 \pm 1.2 \mu\text{M}$ by Dixon plot analysis.

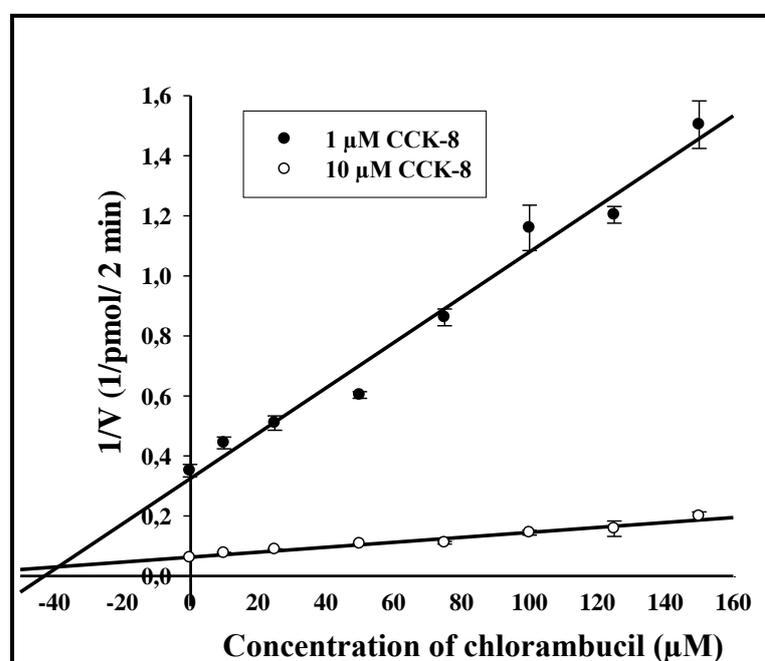

Figure 4.30 Concentration dependent inhibition of OATP1B3 mediated CCK-8 uptake by chlorambucil. The uptake of [^3H] CCK-8 was measured in Hank's buffer solution

containing 5 nM [^3H] CCK-8 and either 995 nM or 9.995 μM unlabeled CCK-8 in the presence of 0, 10 μM , 25 μM , 50 μM , 75 μM , 100 μM , 125 μM , and 150 μM chlorambucil for 2 min. Dark circles represent the uptake values at 1 μM CCK-8 and clear circles represent uptake at 10 μM CCK-8. Figure is of one representative experiment and K_i value was calculated from two such experiments. Data are means \pm SEM of two independent experiments with three repeats each.

4.4.3.2 Concentration dependent inhibition of mitoxantrone on OATP1B3 mediated CCK-8 uptake

The uptake of [^3H] CCK-8 measured in buffer solutions containing 1 μM and 10 μM CCK-8 in the presence of increasing concentrations of mitoxantrone, revealed a K_i value of 3.1 ± 0.1 μM for the intercalating agent, mitoxantrone (Fig. 4.31).

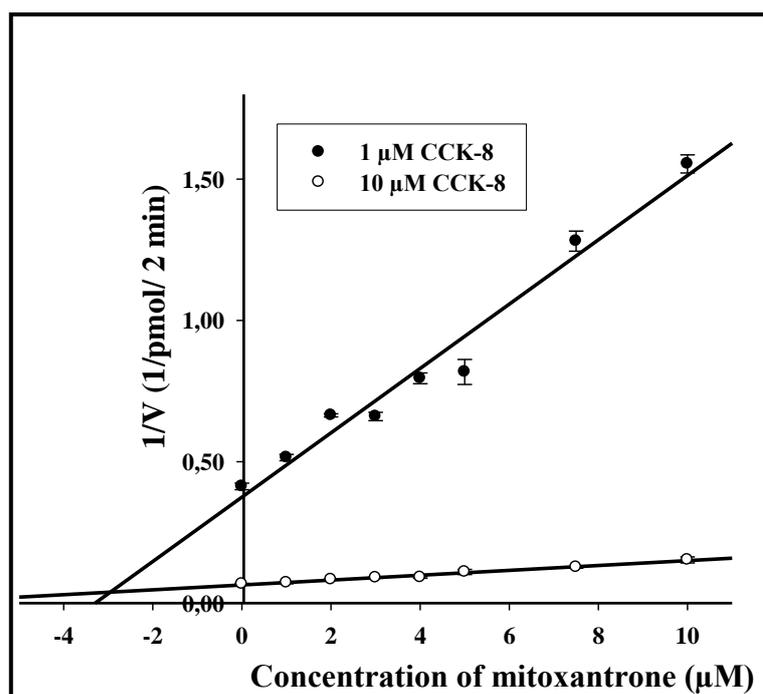

Figure 4.31 Concentration dependent inhibition of OATP1B3 mediated CCK-8 uptake by mitoxantrone. The uptake of [^3H] CCK-8 was measured in Hank's buffer solution containing 5 nM [^3H] CCK-8 and either 995 nM or 9.995 μM unlabeled CCK-8 in the presence of 0, 1 μM , 2 μM , 3 μM , 4 μM , 5 μM , 7.5 μM , and 10 μM mitoxantrone for 2 min. Dark circles represent the uptake values at 1 μM CCK-8 and clear circles represent uptake at 10 μM CCK-8.

Figure is of one representative experiment representative and K_i value was calculated from two such experiments. Data are means \pm SEM of two independent experiments with three repeats each.

4.4.3.3 Concentration dependent inhibition of vinblastine on OATP1B3 mediated CCK-8 uptake

Dixon plot analysis of the uptake of [3 H] CCK-8 in solutions containing 1 μ M or 10 μ M CCK-8 in the presence of increasing concentrations of vinblastine revealed the K_i value of OATP1B3 for vinblastine to be $18.6 \mu\text{M} \pm 1.4 \mu\text{M}$ (Fig. 4.32).

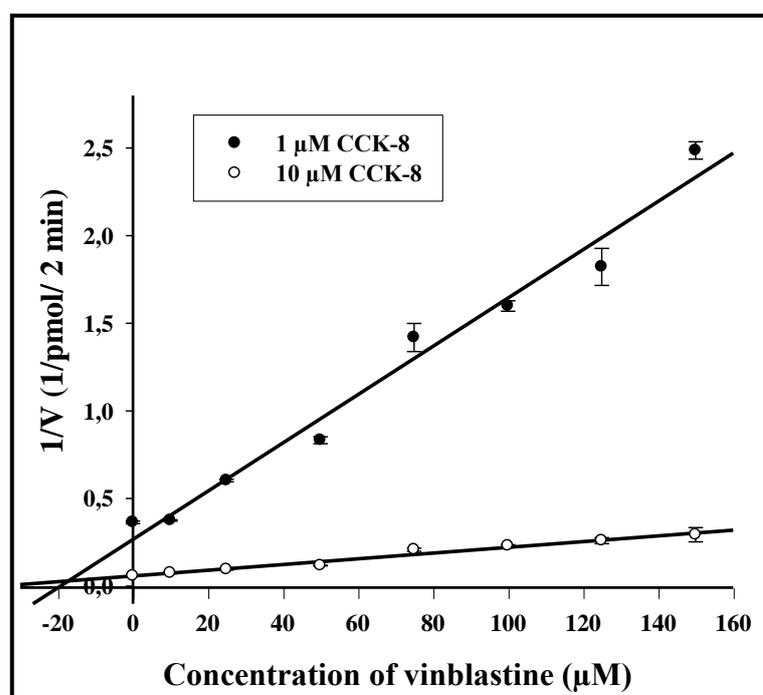

Figure 4.32 Concentration dependent inhibition of OATP1B3 mediated CCK-8 uptake by vinblastine. The uptake of [3 H] CCK-8 was measured in Hank's buffer solution containing 5 nM [3 H] CCK-8 and either 995 nM or 9.995 μM unlabeled CCK-8 in the presence of 0, 10 μM , 25 μM , 50 μM , 75 μM , 100 μM , 125 μM , and 150 μM vinblastine for 2 min. Dark circles represent the uptake values at 1 μM CCK-8 and clear circles represent uptake at 10 μM CCK-8. Figure is representative from one experiment and K_i value was calculated from two such experiments. Data are means \pm SEM of two independent experiments with three repeats each.

4.4.3.4 Concentration dependent inhibition of vincristine on OATP1B3 mediated CCK-8 uptake

Dixon plot analysis of the uptake of [³H] CCK-8 in solutions containing 1 μM or 10 μM CCK-8 in the presence of increasing concentrations of vincristine revealed the K_i value of OATP1B3 for vincristine to be $17.6 \mu\text{M} \pm 0.03 \mu\text{M}$ (Fig. 4.33)

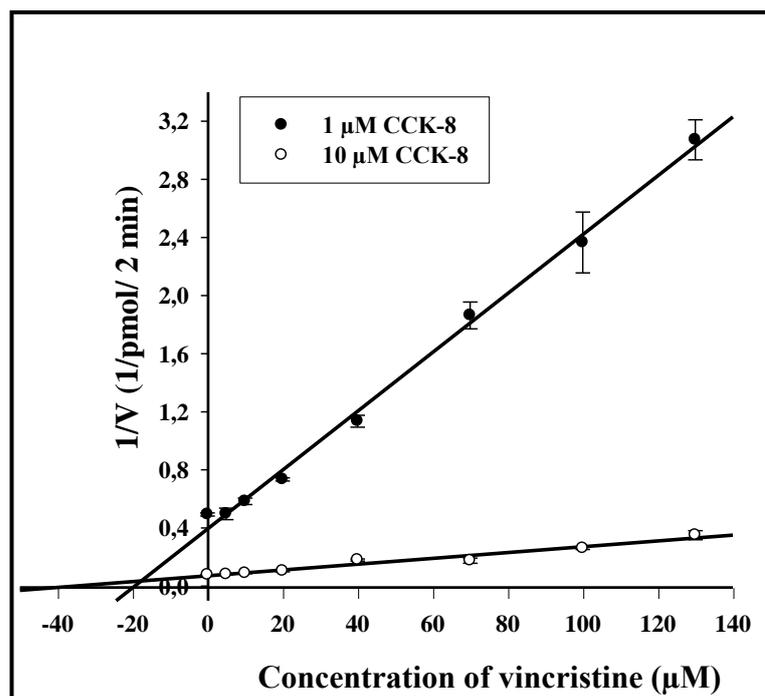

Figure 4.33 Concentration dependent inhibition of OATP1B3 mediated CCK-8 uptake by vincristine. The uptake of [³H] CCK-8 was measured in Hank's buffer solution containing 5 nM [³H] CCK-8 and either 995 nM or 9.995 μM unlabeled CCK-8 in the presence of 0, 5 μM , 10 μM , 20 μM , 40 μM , 70 μM , 100 μM , and 130 μM vincristine for 2 min. Dark circles represent the uptake values at 1 μM CCK-8 and clear circles represent uptake at 10 μM CCK-8. Figure is representative from one experiment and K_i value was calculated from two such experiments. Data are means \pm SEM of two independent experiments with three repeats each.

4.4.3.5 Concentration dependent inhibition of paclitaxel on OATP1B3 mediated CCK-8 uptake

Measurement of the uptake of [^3H] CCK-8 at two different substrate concentrations in the presence of increasing concentration of paclitaxel revealed the K_i value to be $1.8 \pm 0.03 \mu\text{M}$ by Dixon plot analysis (Fig. 4.34).

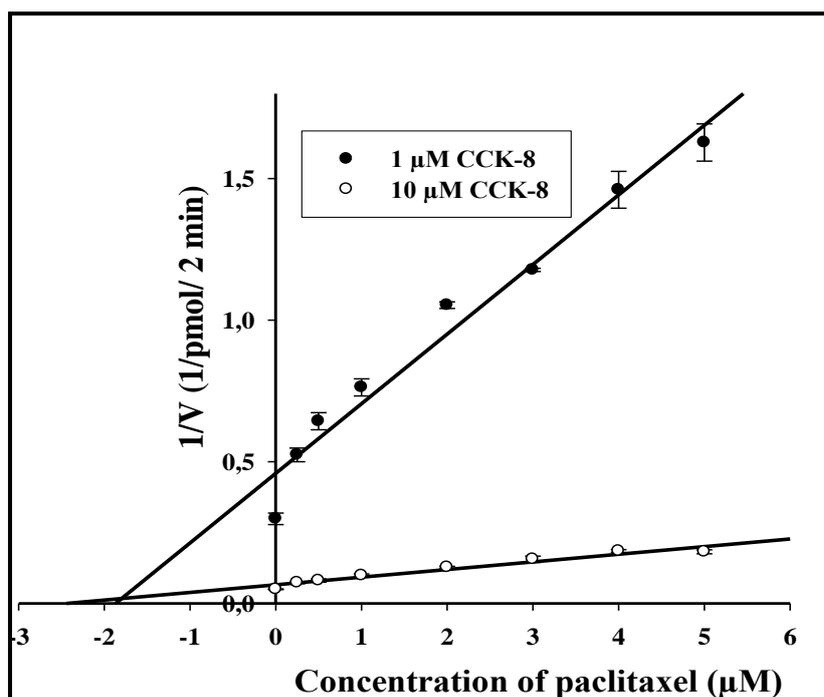

Figure 4.34 Concentration dependent inhibition of OATP1B3 mediated CCK-8 uptake by paclitaxel. The uptake of [^3H] CCK-8 was measured in Hank's buffer solution containing 5 nM [^3H] CCK-8 and either 995 nM or 9.995 μM unlabeled CCK-8 in the presence of 0, 0.25 μM , 0.5 μM , 1 μM , 2 μM , 3 μM , 4 μM , and 5 μM paclitaxel for 2 min. Dark circles represent the uptake values at 1 μM CCK-8 and clear circles represent uptake at 10 μM CCK-8. Figure is representative from one experiment and K_i value was calculated from two such experiments. Data are means \pm SEM of two independent experiments with three repeats each.

4.4.3.6 Concentration dependent inhibition of etoposide on OATP1B3 mediated CCK-8 uptake

Measurement of the uptake of [^3H] CCK-8 at two different substrate concentrations in the presence of increasing concentration of etoposide revealed the K_i value to be $13.5 \pm 0.28 \mu\text{M}$ by Dixon plot analysis (Fig. 4.35).

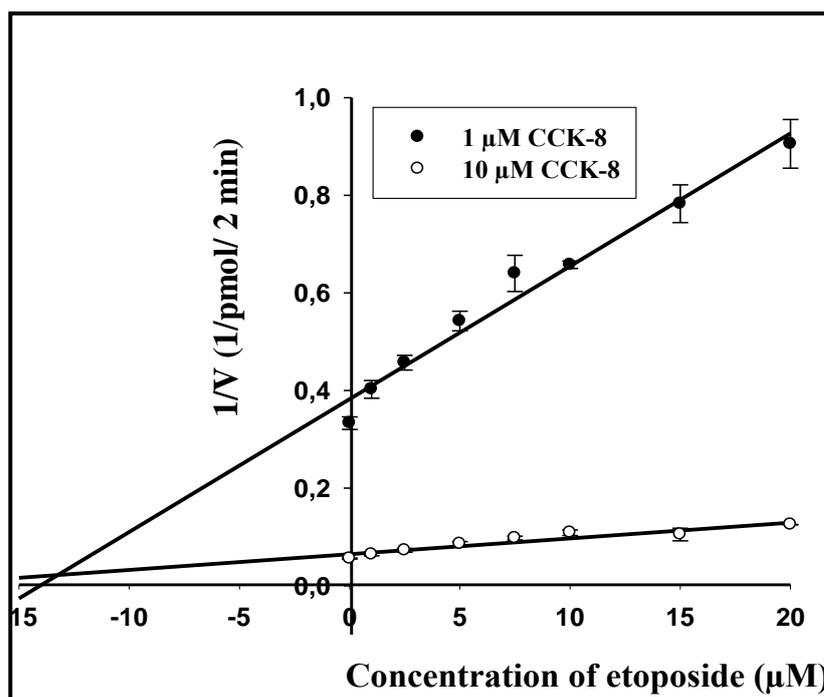

Figure 4.35 Concentration dependent inhibition of OATP1B3 mediated CCK-8 uptake by etoposide. The uptake of [^3H] CCK-8 was measured in Hank's buffer solution containing 5 nM [^3H] CCK-8 and either 995 nM or 9.995 μM unlabeled CCK-8 in the presence of 0, 1 μM , 2.5 μM , 5 μM , 7.5, 10 μM , 15 μM , and 20 μM etoposide for 2 min. Dark circles represent the uptake values at 1 μM CCK-8 and clear circles represent uptake at 10 μM CCK-8. Figure is representative from one experiment and K_i value was calculated from two such experiments. Data are means \pm SEM of two independent experiments with three repeats each.

The results depicted so far highlight the ability of a transporter protein to interact with certain antineoplastic compounds that might lead to drug-drug interactions influencing the chemotherapy regimens of tumor treatment. There is yet another dimension in which the

transporter proteins influence the effectiveness of a chemotherapy regimen; their expression status in the tumors. Expression of uptake transporters has been shown to vary markedly among different tumors. There are many different stages in the metabolism of a cell where the expression of a gene is regulated, the other group of experiments are focused on the regulation of a transporter protein encoded by the gene SLC22A3; the organic cation transporter 3 (OCT3).

4.5. Expression of SLC22A3 in A498, ACHN, 786-O and LN 78 cells

Earlier studies conducted in the lab showed a variable expression pattern of OCT3 in renal carcinoma cell lines. The current experiments are aimed to find the reason for this variable expression of OCT3. The expression pattern found was reestablished prior to experiments on the regulation aspects were performed.

Using TaqMan primers specific for OCT3 and GAPDH, the expression of OCT3 in the four renal carcinoma cells was measured. qRT-PCR of cDNA prepared from RNA isolated from the four cell lines showed a clear pattern wherein the difference between the ΔC_t value between A498 and ACHN cells was around 12 cycles, consistent with the earlier finding in the lab (Fig. 4.36).

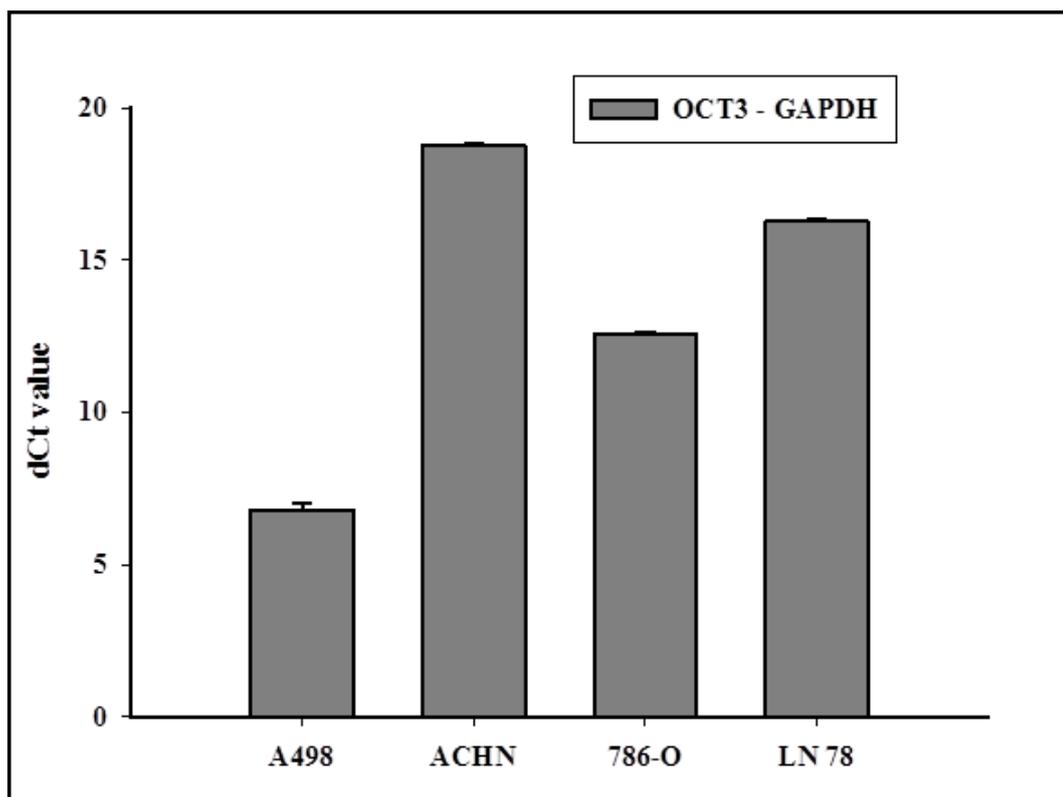

Figure 4.36 Expression of OCT3 in renal carcinoma cell lines. qRTPCR was conducted with cDNA prepared from total RNA isolated from the cells. The Ct values of OCT3 and GAPDH were obtained and the Δ Ct values were obtained by subtracting the Ct (cycle of threshold) of GAPDH from the Ct value of OCT3.

4.6. Effect of inhibition of DNA methylation on expression of OCT3

To find out whether inhibition of DNA methylation would have any effect on the expression of OCT3, cells were treated with 5-aza-2'-deoxy-cytidine, an inhibitor of DNA methyltransferase. Incubation of ACHN cells with 5 μ M resulted in a decrease of ca. 2 in Δ Ct value on the expression of OCT3 in these cells. However, there was no further increase in the increase of expression of OCT3 with increase in the concentration of 5-aza-2'-deoxy-cytidine (Fig. 4.37).

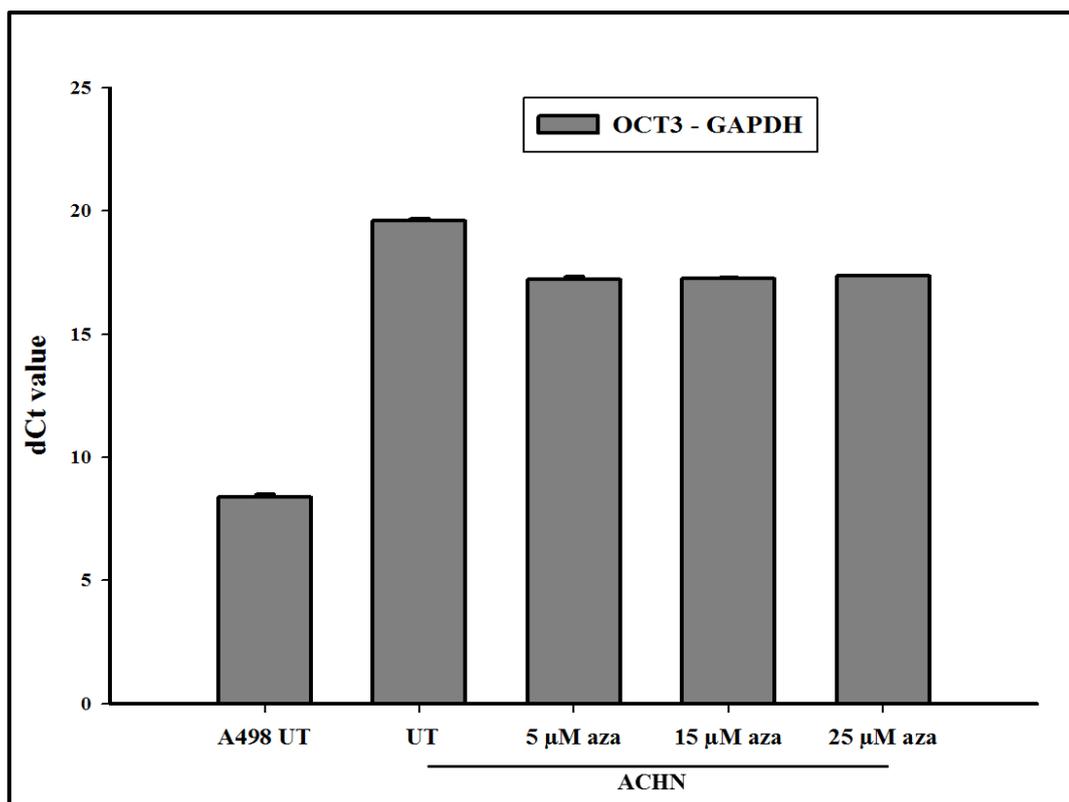

Figure 4.37 Expression of OCT3 in ACHN cells treated with 5-aza-2'-deoxy-cytidine.

ACHN cells were treated with 5 μ M, 15 μ M, or 25 μ M 5-aza-2'-deoxy-cytidine for 72 h. qRT-PCR was conducted with cDNA prepared from total RNA isolated from these cells along with untreated A498 and ACHN cells. The Ct values of OCT3 and GAPDH were obtained and the Δ Ct values were obtained by subtracting the Ct (cycle of threshold) of GAPDH from the Ct value of OCT3. UT- untransfected, aza- 5-aza-2'-deoxy-cytidine.

4.7. Effect of inhibition of histone deacetylation on the expression of OCT3

To find out whether inhibition of acetylation of histones has any effect on the expression of OCT3, cells were treated with valproic acid, an inhibitor of the enzyme histone deacetylase. Incubation of ACHN cells with 0.5 mM, 5 mM or 10 mM valproic acid for 24 h did not result in any change in Δ Ct value compared to the untreated ACHN cells (Fig. 4.38).

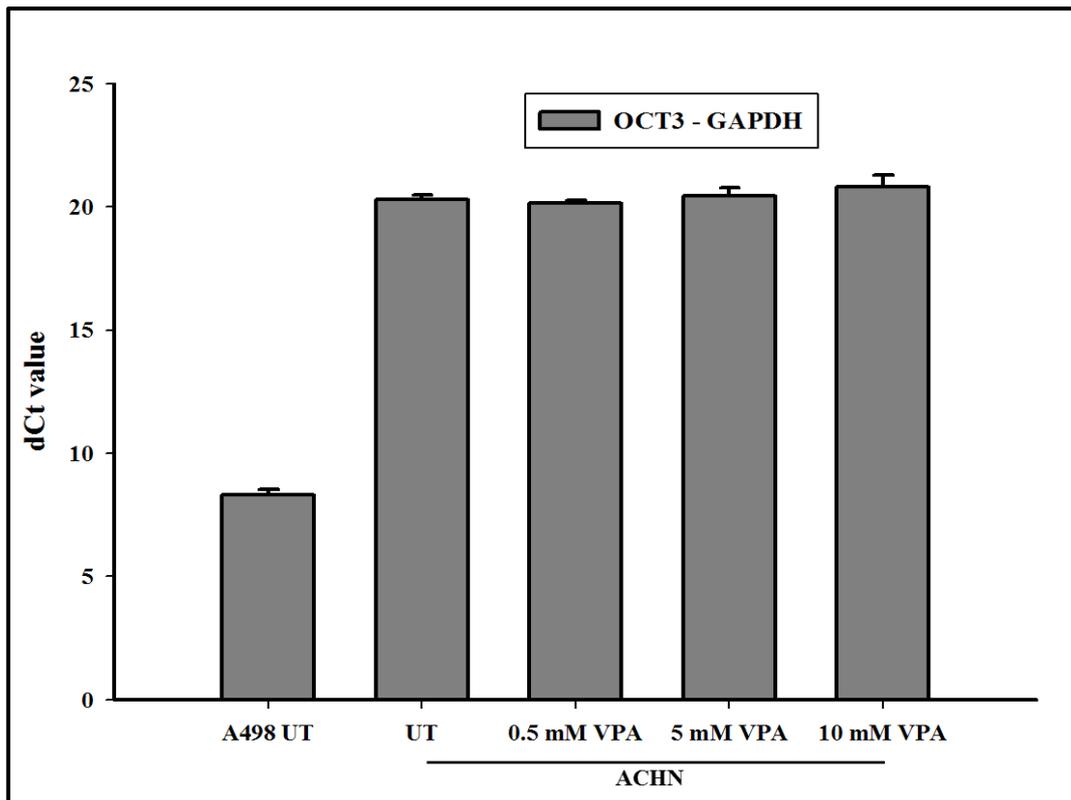

Figure 4.38 Expression of OCT3 in ACHN cells treated with valproic acid. ACHN cells were treated with 0.5 mM, 5 mM or 15 mM valproic acid for 24 h. qRT-PCR was conducted with cDNA prepared from total RNA isolated from these cells along with untreated A498 and ACHN cells. The Ct values of OCT3 and GAPDH were obtained and the Δ Ct values were obtained by subtracting the Ct (cycle of threshold) of GAPDH from the Ct value of OCT3. UT-untransfected. VPA-valproic acid.

4.8. Determination of methylation status of CpG islands by Ion-Torrent sequencing of bisulfite treated DNA

The fragments of interest were amplified, from all the cell lines, by PCR using the suitable annealing conditions, analyzed on a 2% agarose gel, and the bands were detected in a gel documentation chamber (Fig. 4.39).

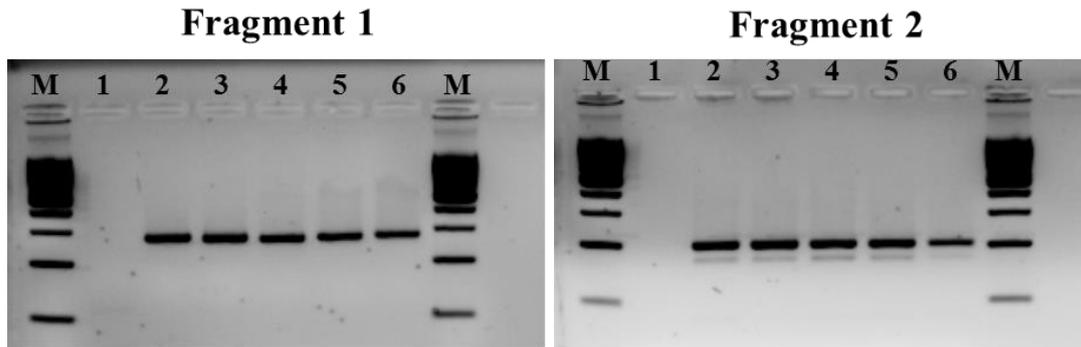

Figure 4.39 Amplification of fragments 1 and 2 from the promoter region of SLC22A3. The fragments 1 and 2 were amplified using specific primers and analyzed on a 2 % agarose gel. Lanes: M-100 bp ladder, 1 - negative control, 2 - A498, 3 - ACHN, 4 - RCCNG-1, 5 - 786-O, and 6 - LN78.

The obtained fragments were further subjected to adapter PCR wherein they were further amplified using specific primers which would make them distinct during the sequencing procedure (Fig. 4.40).

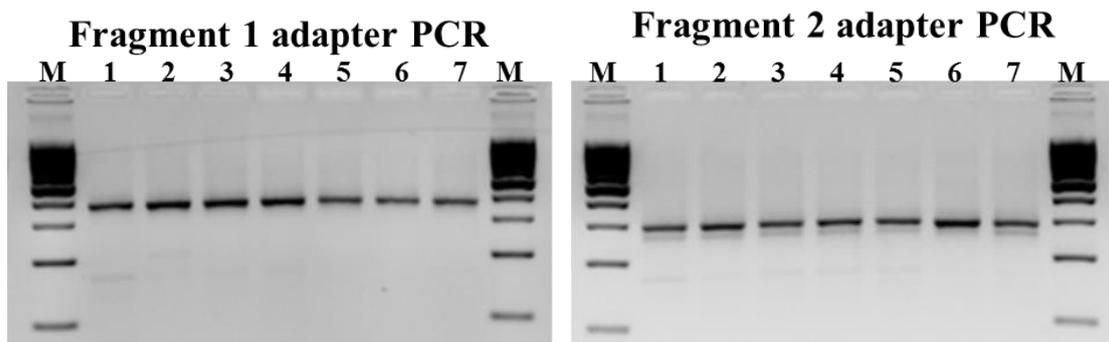

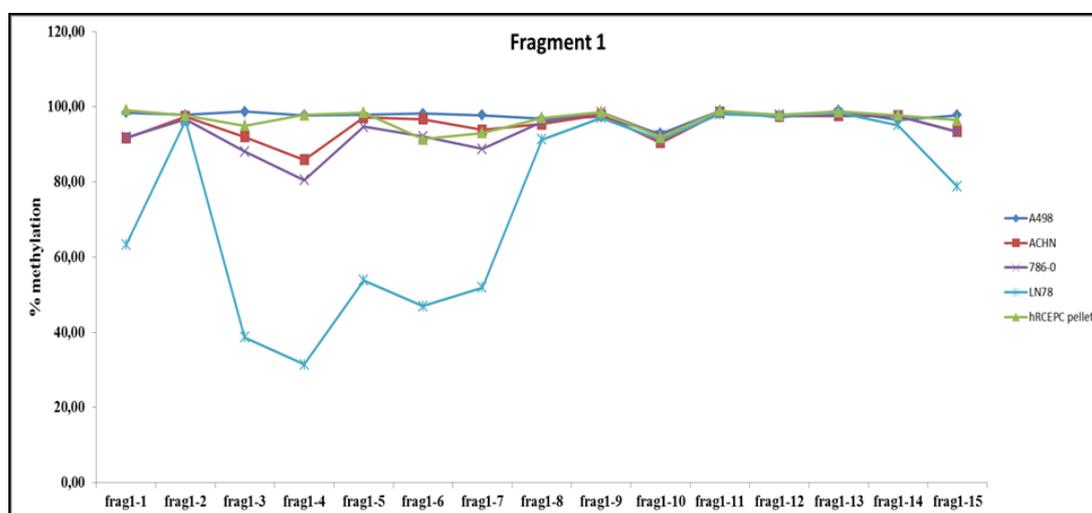

Figure 4.40 Adapter PCR of amplified fragments. The fragments 1 and 2 were further amplified using specific primers that contained barcode sequences, which make them distinctly recognized by the sequencer, and analyzed on a 2 % agarose gel. Lanes: M-100 bp ladder, 1 - A498, 2 - ACHN, 3 - RCCNG-1, 4 - 786-O, 5 - LN78, 6 - renal epithelial cell pellet, 7 - hepatocytes.

These fragments were pooled, run on a 2 % agarose gel and extracted from the gel. They were quantitated and used to prepare the template positive ion sphere particles which were sequenced. The methylation status of the CpG islands in the promoter fragments 1 and 2 was obtained by comparing the sequence obtained in the ion torrent sequencing run with the original sequence of the fragments amplified. There were 15 CpG residues in the fragment 1 and they did not show a considerable difference among the renal carcinoma cells and the human renal cortical epithelial cell pellet used as a positive control. However, there was a considerable difference at the CpG positions 3-7 in LN78 cell line. The other CpG islands had similar levels of methylation as the other cell lines.

The 16 CpG islands in fragment 2 did not show any marked differences between the four renal carcinoma cell lines. However, there was a high degree of hypomethylation in the control cells at the positions, 2, 3, and 9-16 (Fig. 4.41).

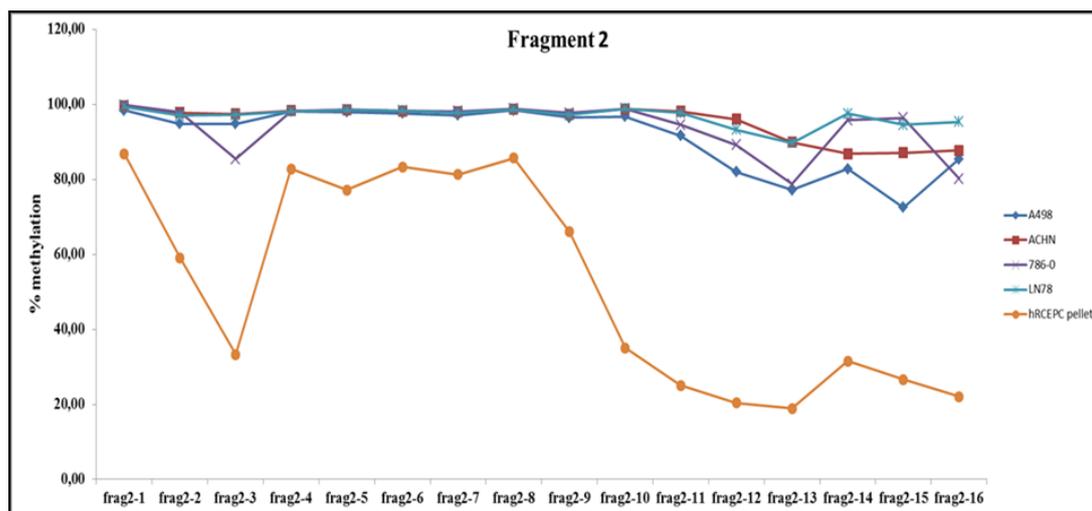

Figure 4.41 Analysis of methylation status of CpG islands in fragments 1 and 2 of the promoter region of SLC22A3. The fragments 1 and 2 in the promoter region were amplified using specific primers and subjected to ion torrent sequencing to analyze the methylation status of the CpG islands present in these fragments. The results were downloaded from the Torrent server within the program and % methylation of each residue was calculated. The % methylation obtained was plotted against the number of CpG residue counted from the 5' end of the template. hRCEPC – human renal cortical epithelial cell pellet.

4.9. qRT-PCR of expression of selected microRNAs in A498 and ACHN cells

From the microRNA predicting programs, 11 microRNA species were selected as they were predicted from more than of the stronger prediction programs used for the study. qRT-PCR of the selected microRNAs in A498 and ACHN cells revealed that two microRNA species hsa-mir-204 and hsa-mir-143 were highly expressed in A498 cells having the highest OCT3 expression. The small nucleolar RNAs, RNU48 and RNU43 were used as internal controls and ΔCt values were calculated by subtracting the Ct values of these RNAs from the corresponding microRNA. $2^{-\Delta\Delta Ct}$ values were calculated by subtracting the ΔCt values of microRNAs in ACHN cells from that of the corresponding values in A498 cells. There were no microRNA species among the selected microRNAs which was

highly expressed in ACHN cells which had low OCT3 expression (Fig.4.42). Two of the selected microRNAs did not show any expression in either of the cell lines.

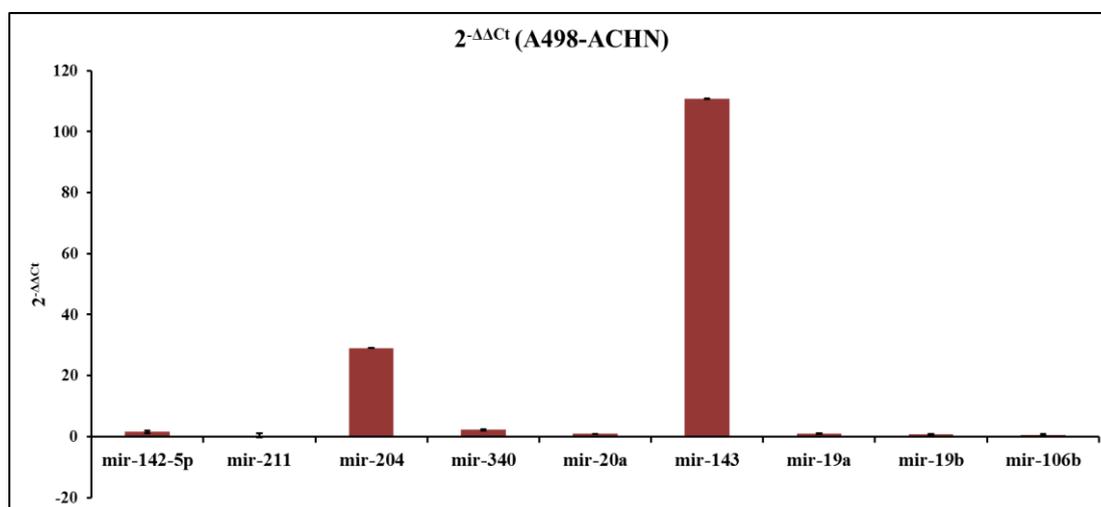

Figure 4.42 qRT-PCR of microRNAs in A498 and ACHN cells. The ΔC_t values were calculated by subtracting the expression of the control RNA (RNU48 and RNU43) from the corresponding microRNAs. The $\Delta\Delta C_t$ values were obtained by taking A498 cells as reference.

4.10. Manipulation of levels of hsa-mir-204 and hsa-mir-143 in A498 and ACHN cells using microRNA mimics and antimirs

Transient transfection of microRNA mimics of hsa-mir-204 and hsa-mir-143 into ACHN cells led to an increase in the expression of mir-204 and mir-143, respectively; however, there was no consequence of this increase of the microRNAs on the expression level of OCT3. Similarly, there was a decrease in the expression levels of microRNAs 204 and 143 in A498 cells upon transfection with corresponding antimirs, but this did not lead to any change in the expression of OCT3 in these cells compared to untransfected cells (Fig. 4.43).

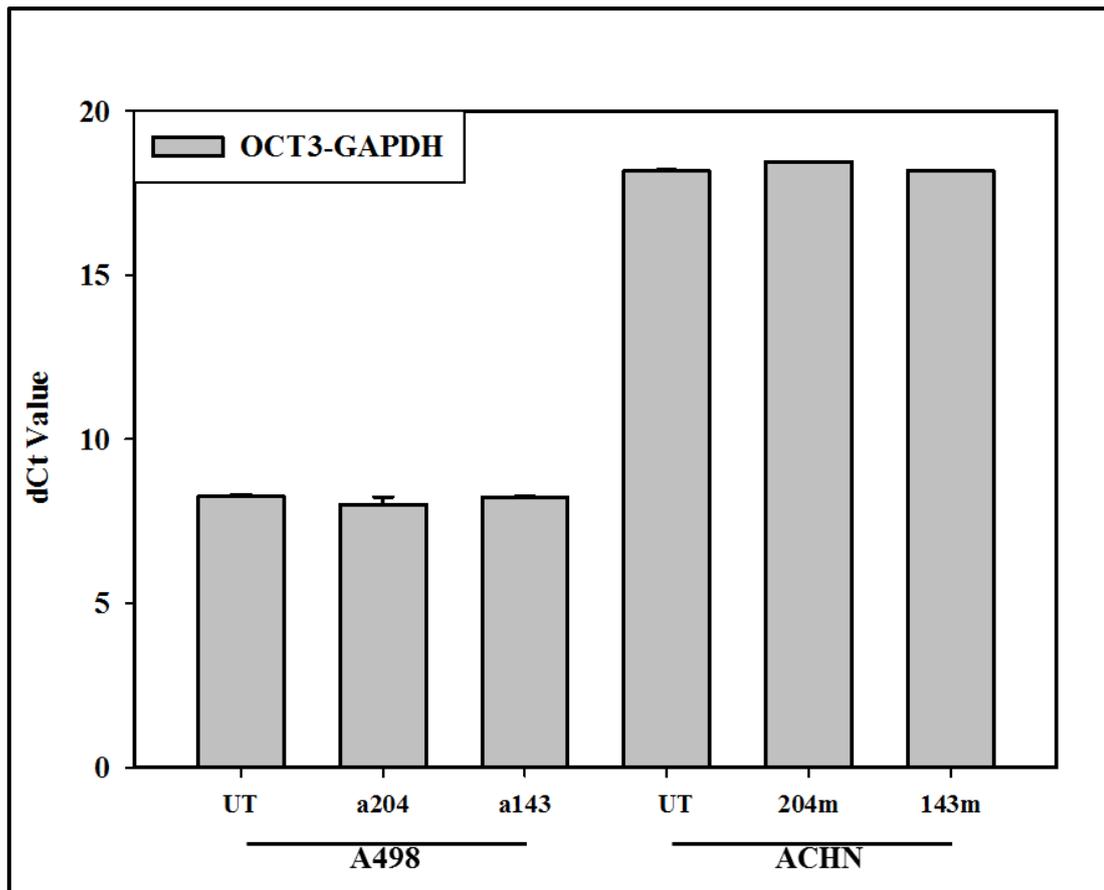

Figure 4.43 qRT-PCR of SLC22A3 in A498 and ACHN cells upon transfection with microRNA mimics and antimirs, respectively. Mimics (m) and antimirs (a) directed against microRNAs hsa-mir-204 and hsa-mir-143 were transiently transfected into A498 and ACHN cells. qRT-PCR was conducted with cDNA prepared from total RNA isolated from the cells. The Ct values of OCT3 and GAPDH were obtained and the Δ Ct values were obtained by subtracting the Ct (cycle of threshold) of GAPDH from the Ct value of OCT3. UT- untransfected.

4.11. Genome wide analysis of microRNA in A498, ACHN, 786-O and LN 78 cells

Since our earlier approach of using prediction algorithms of microRNA binding to 3' UTR of OCT3 to find out microRNAs potentially involved in regulating the expression of OCT3 did not yield a reliable result, we proceeded for the next generation sequencing of genome wide microRNA analysis. The run and analysis were performed by our

colleagues at the DNA microarray and deep sequencing facility in Goettingen, under the supervision of Dr. Gabriela Salinas-Riester. For this purpose, the total RNA was isolated from A498, ACHN, 786-O and LN78 cells and subjected to next generation sequencing for genome wide analysis of microRNAs in the cells. The sequencing was performed on a HiSeq 2000 platform and the results were obtained as microRNA expression in one cell line vs microRNA present in another cell line. Many parameters were obtained such as mean expression among the triplicates, their ratios, the fold change in logarithmic scale with standard error and the significance values of the observed differences in expression between two RCCs.

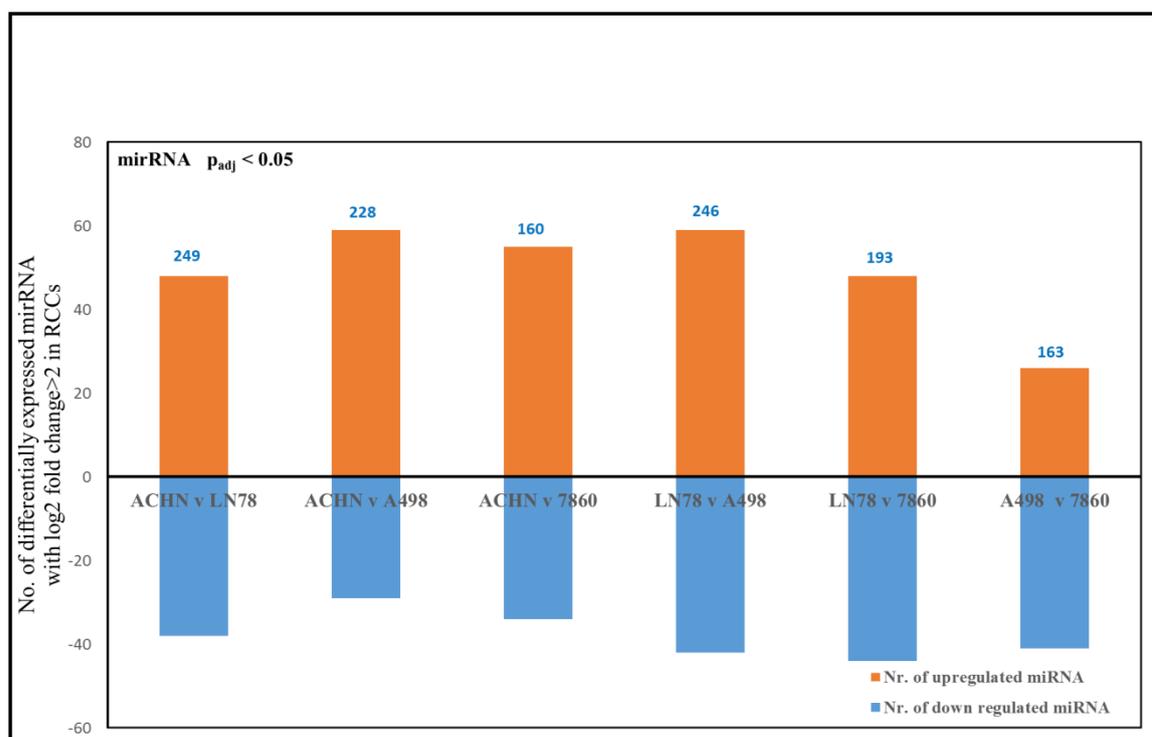

Figure 4.44. Expression patterns of various RNA species in the four cell lines.

The microRNAs which have a \log_2 fold change value of more than 2 are presented against each comparison of cell lines. The numbers above the bars indicate the total number of microRNAs with adjusted p value of < 0.05 . The orange and blue bars depict the number of upregulated and down regulated microRNAs, respectively, in the cell line (A) in the representation of A vs B.

As can be seen in figure 4.44, there is a huge difference of expression of many of the small length RNAs among the cell lines. The microRNA species which have a log₂ fold change of more than 2 are being analyzed further.

Furthermore, with a focus on ACHN cell line, which has least expression of OCT3, we found that a number of microRNAs are highly expressed in this cell line as depicted in figure 4.45.

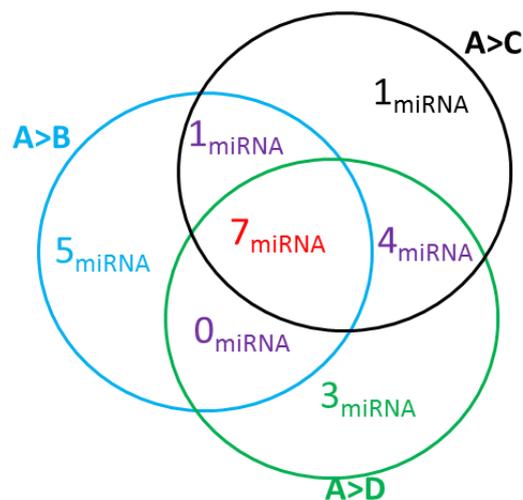

Figure 4.45 Number of microRNAs highly expressed in ACHN (A) and with zero expression in LN78 (B), A498 (C) and 7680 (D) cells.

In addition, there were some microRNAs that were found to be highly expressed in LN78, A498, and 786-O cells but not in ACHN cells as represented in figure 4.46

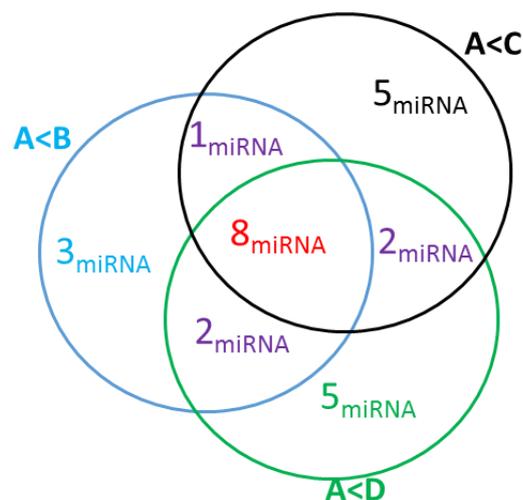

Figure 4.46 Number of microRNAs highly expressed in LN78 (B), A498 (C) and 7680 (D) cells but not in ACHN (A) cells

5. Discussion

An important step in the elimination of drugs and xenobiotics is the absorption of these molecules from blood into the hepatocytes. It is not yet known, how many of the antineoplastic agents gain entry into the cells and what are the factors that influence this process. The objectives of the study were 1) To find whether the liver specific transporter proteins of SLC superfamily are involved in the interaction and eventual uptake of these compounds and 2) To understand the mechanisms of regulation of one of the SLC protein, the organic cation transporter 3, in renal carcinoma cells.

5.1. Interaction of OAT2, NTCP, OATP1B1 and OATP1B3 with antineoplastic compounds

The present study is focused on four transporter proteins specifically expressed in the liver, organic anion transporter 2 (OAT2), sodium taurocholate cotransporting polypeptide (NTCP), and organic anion transporting polypeptides 1B1 (OATP1B1) and 1B3 (OATP1B3), and tested for their interaction with antineoplastic compounds. For studying these interactions, stably transfected human embryonic kidney cells expressing the corresponding transporter protein were used. The expression and function of the transporter proteins was characterized and used as a platform to study the interactions of transporter proteins with antineoplastic agents. The compounds that have been used as substrates for the transporter proteins have been described in literature and include cyclic guanosine monophosphate (cGMP) for OAT2, estrone-3-sulfate for NCTP and OATP1B1, while cholecystokinin octapeptide (CCK-8) was shown to be substrate of OATP1B3, respectively [11;152-155]. The Michaelis-Menten constant (K_m) values generated in our expression systems were in line with the previous observations. We used one tenth of the K_m values of the model substrate to perform the experiments under

standardized conditions for all transporters. Using the uptake of the model substrates in the absence of any antineoplastic agent as a reference, we measured the uptake in the presence of 100 μM of each one of the compounds. The high concentration of the compounds was used to find out any potential interactions. We considered, for kinetic analysis, only those interactions which led to an inhibition of the uptake (by 100 μM) to less than 40% of buffer control. We report, for the first time, a very high affinity of OAT2 for the antineoplastic drugs bendamustine and irinotecan, apart from a very strong interaction with paclitaxel as reported earlier [12]. Dixon plot analysis revealed the K_i values of OAT2 for bendamustine, irinotecan, and paclitaxel to be $43.3 \pm 4.33 \mu\text{M}$, $26.4 \pm 2.34 \mu\text{M}$ and $10.4 \pm 0.45 \mu\text{M}$, respectively. None of the antineoplastic compounds studied inhibited the uptake of NTCP mediated estrone-3-sulfate to less than 40 % of buffer control. Our observation of a strong interaction of OAT2 with paclitaxel is in line with a previous report [4] wherein the authors have measured the uptake of radiolabeled paclitaxel in OAT2 expressing oocytes. However, we did not see any interaction of OAT2 with 5-fluorouracil, as observed in the same report. It is not uncommon to see such differences in the substrate uptakes between those performed in oocytes and those performed in HEK cells or CHO cells. Besides OAT2, paclitaxel is also shown to be transported by OATP1B1 and OATP1B3 [156], and our experiments also show strong interaction between the two transport proteins and paclitaxel.

We observed a strong interaction of vinblastine and paclitaxel with OATP1B1. In addition, we observed a very strong stimulation of OATP1B1-mediated estrone 3-sulfate uptake by irinotecan. Similarly, OATP1B3 showed many significant interactions with the antineoplastic compounds tested. This might be an indication of its broad specificity for the substrates, and highlights its importance in drug mediated cytotoxicity and drug-drug interactions. The compounds chlorambucil, an alkylating agent; mitoxantrone, an

intercalating agent; both the vinca alkaloids vincristine and vinblastine and paclitaxel, the other mitotic inhibitor tested; and the topoisomerase inhibitor etoposide all strongly interacted with varying effectiveness.

Until recently, there was no study showing any interactions of these antineoplastic agents other than paclitaxel with OATP1B1 and OATP1B3. However, in a quest for pharmacophore prediction, a study was conducted with as many as 225 drug-like compounds in search of their ability to interact with these two proteins [157;158]. Although the study was conducted with stably transfected HEK cells as is the case with our experiments, there were a number of similarities as well as differences among the two. The authors used estradiol-17 β -glucuronide as a model substrate for OATP1B1 and OATP1B3 and 20 μ M as the concentration of compounds whose interaction was studied. Similar to their observation, we also found comparably strong interactions of OATP1B1 and OATP1B3 with vinblastine. In addition, we did not find any interaction between methotrexate and OATP1B1 as has been previously reported [159]. However, contrary to that study, we found a very strong inhibition of OATP1B3-mediated CCK-8 uptake by mitoxantrone and etoposide, with K_i values of 15.9 μ M and 3.25 μ M, respectively, suggesting a very high affinity of the transporters for these compounds, apart from paclitaxel which seems to be the antineoplastic agent with the highest affinity of all the compounds tested in this study. Differences like these have been observed in the past and they are shown to arise from the choice of the substrate used in the experiments [160]. This is further strengthened by another study wherein the authors used sodium fluorescein as a substrate and measured the interactions in Chinese Hamster Ovary cells and observed that 10 μ M paclitaxel inhibited the OATP1B1 and OATP1B3 mediated uptake of sodium fluorescein to 16.4 % and 52.9 % of buffer control, respectively [6]. As mentioned above, using estrone-3-sulfate and CCK-8 as substrates, we observed a very strong interaction of

paclitaxel with both the OATP transporters with K_i values of 0.84 μM and 1.8 μM , respectively.

Apart from the inhibition of transporter mediated uptake, we also observed stimulation of uptake of the corresponding substrates. The most pronounced stimulation was observed in the presence of irinotecan on the uptake of estrone 3-sulfate by OATP1B1. Stimulation of OATP mediated uptake by another compound has been observed earlier by Wang *et al* similar to our observation of increased estrone 3-sulfate uptake in the presence of irinotecan [161;162] and also in the study mentioned above [157;158]. The stimulation indicates a complex transport mechanism of OATPs in general and might be due to the presence of more than one binding site on OATPs [163]. Most of the interacting compounds are bulky and hydrophobic, a feature consistent with the notion that OATPs are involved in the transport of such compounds.

Now that the interactions are established between the antineoplastic compounds and OAT2, OATP1B1, and OATP1B3 transporters, more questions arise: firstly, whether these interactions lead to drug-drug interactions *in vivo* and secondly, whether these compounds are transported into the cell. To consider the obtained kinetic parameters for prediction of *in vivo* drug-drug interactions, it is necessary to know the unbound fractions of the antineoplastic compounds in circulation. The unbound fractions of these compounds in circulation were obtained from Goodman and Gilman's "The pharmacological basis of therapeutics" 10th edition and literature [164] and the peak plasma concentrations were calculated as per the standard dosages of administration of these compounds during the course of chemotherapy.

The possibility of a compound interacting with OAT proteins to contribute to drug-drug interactions *in vivo* was described previously [66]. Applying the same principle (unbound

$C_{\max}/IC_{50} \geq 0.1$) to the three inhibitors of OAT2 observed in our study, we found that irinotecan has the potential to contribute to drug-drug interactions *in vivo*, while the compounds bendamustine and paclitaxel do not. Similarly, in the case of OATPs, for a compound to be possibly involved in drug-drug interaction, it was suggested that the IC_{50} value shall be less than or equal to 10 times the unbound C_{\max} of the drug [66]. Applying the same principle with the IC_{50} values, the antineoplastic compound paclitaxel in the case of OATP1B1, and the compounds mitoxantrone, paclitaxel and etoposide for OATP1B3 are potential candidates to inhibit the corresponding transporter protein *in vivo* and contribute to drug-drug interactions. The following table summarizes the unbound fraction, and the peak plasma concentration of the antineoplastic compounds interacting with transporter proteins.

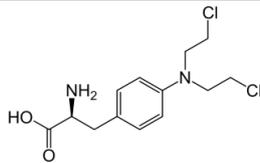

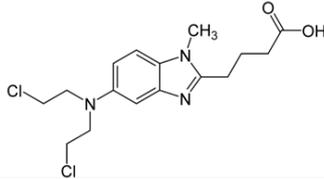

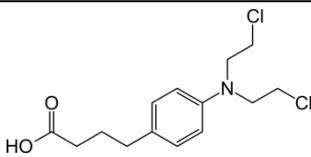

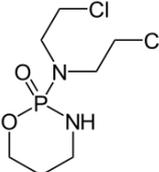

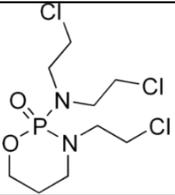

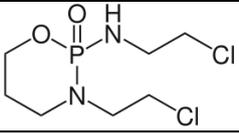

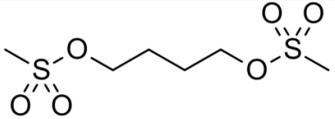

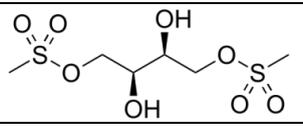

Transporter protein	Compounds	Fraction of unbound compound ^a	Peak plasma concentration ^b	IC_{50} values ^c	Possibility of drug-drug interaction ^d
OAT2	Bendamustine	0.05	14.8 μ M	16.88 μ M	No
OAT2	Irinotecan	0.51	2.89 μ M	7.55 μ M	Yes
OAT2	Paclitaxel	0.12	0.85 μ M	1.44 μ M	No
OATP1B1	Vinblastine	0.14	5.75 μ M	46.8 μ M	No
OATP1B1	Paclitaxel	0.12	0.85 μ M	0.28 μ M	Yes
OATP1B3	Chlorambucil	0.01	1.67 μ M	80.7 μ M	No
OATP1B3	Mitoxantrone	0.25	15.56 μ M	3.39 μ M	Yes
OATP1B3	Vinblastine	0.14	5.75 μ M	43.5 μ M	No
OATP1B3	Vincristine	0.4	0.56 μ M	36.78 μ M	No
OATP1B3	Paclitaxel	0.12	0.85 μ M	0.26 μ M	Yes
OATP1B3	Etoposide	0.12	45.8 μ M	4.18 μ M	Yes

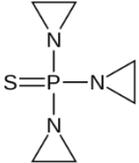

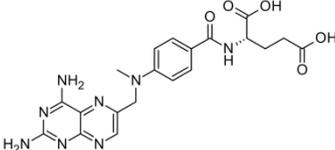

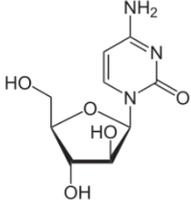

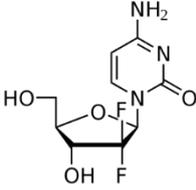

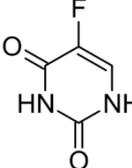

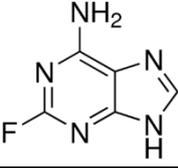

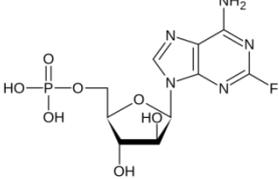

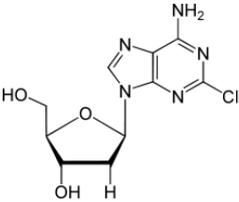

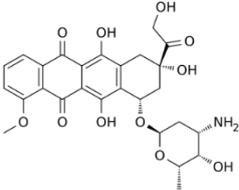

Table 5.1. Possibility of compounds to contribute to the transporter mediated drug-

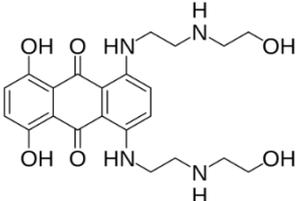

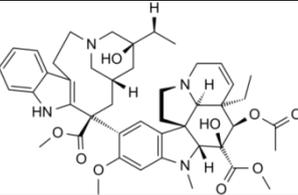

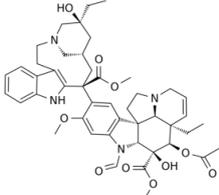

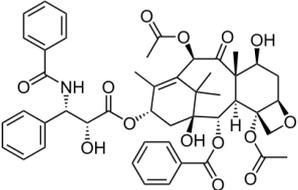

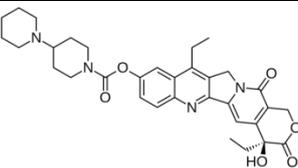

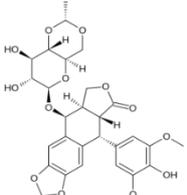

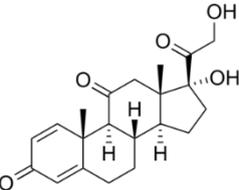

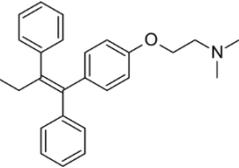

drug interactions. ^aThe fraction of compound unbound to protein was obtained from literature [164] and from BC cancer agency drug manual. ^bThe peak plasma concentrations were obtained from Goodman and Gilman's "The pharmacological basis of therapeutics" 10th edition and literature [165]. ^cIC₅₀ values were calculated from uptake values measured at 1 μ M cGMP substrate or 0.25 μ M ES or 1 μ M CCK-8 as substrate, respectively, in the presence of increasing concentration of the corresponding antineoplastic compound. ^dPossibility of contribution of drug-drug interactions *in vivo* is calculated from literature[166].

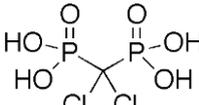

To understand the selectivity of transporter proteins for some of the antineoplastic drugs, we analyzed the molecular parameters of the compounds using the MarvinSketch software (Tab. 5.2). The obtained parameters logP, logD, polar surface area (psa) and net charge at pH 7.4, did not markedly vary among the compounds which interacted with OAT2 and the compounds which did not interact. Moreover, the net charge at pH 7.4 of bendamustine, irinotecan and paclitaxel was -1, +1 and 0, respectively. In addition, we obtained that 87.4 % of vinblastine at pH 7.4 exists in a "+2" ionization state (Table 5.2). Likewise, 99.5 % of paclitaxel exists in an uncharged state at the same pH. This is at odds with the fact that OATP1B1 interacts with and transports negatively charged species. It has also been proposed that high molecular weight (> 300 g/mol) is one of the various criteria that are responsible for distinction of a compound to be a substrate of OATPs [6]. The fact that both these compounds are bulky high molecular weight molecules (810.9 g/mol and 853.9 g/mol, respectively) seems to support their candidature. However, the selectivity of the protein for vinblastine, but not for vincristine (also a "+2" charged compound, with comparable molecular weight of 824.9 g/mol) suggests that there is some other specificity factor that drives these interactions.

Table 5.2 Molecular parameters of the compounds used in the study

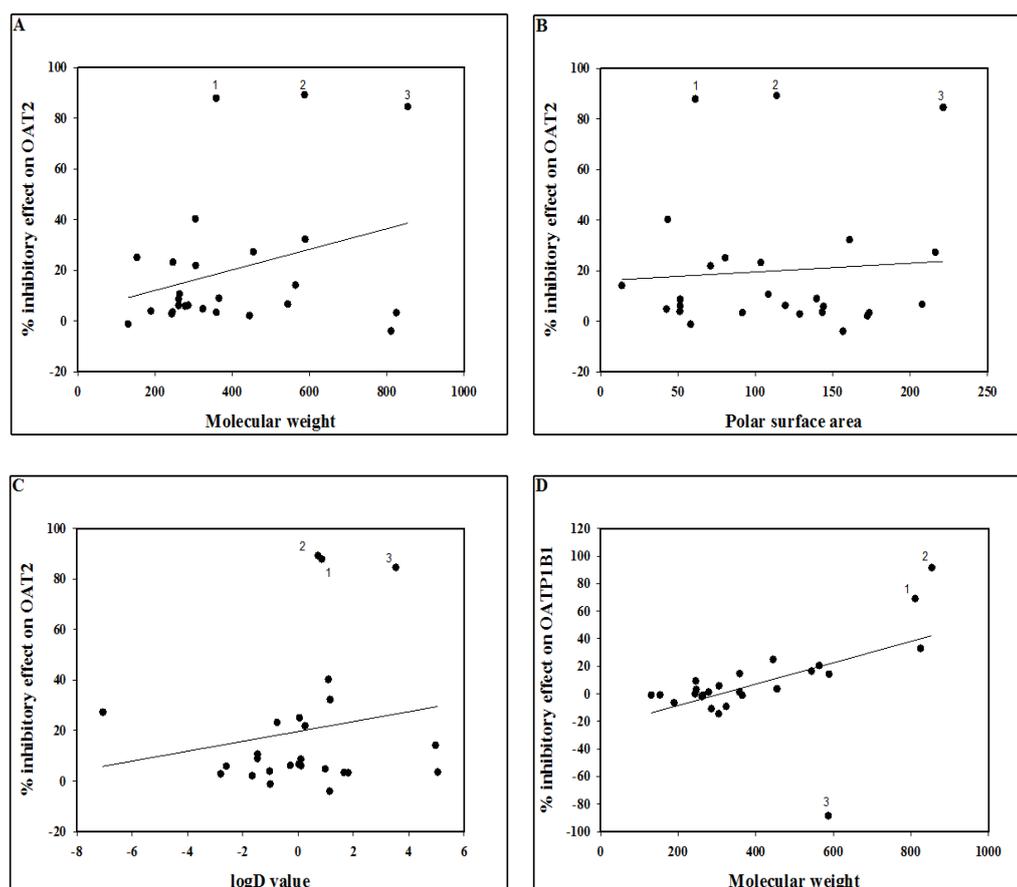

Compound	Chemical structure	Mol. Wt. (g/mol)	logP	logD at pH 7.4	Polar surface area at pH 7.4	Net charge at pH 7.4
Alkylating agents

----------------	---	--------	-------	-------	--------	--

The polar surface area was not markedly different either among the compounds which inhibited the transporter activity of OAT2, OATP1B1 or OATP1B3 and those which did not (Figure 5.1). Similarly the other parameters like logP value or logD value were not considerably different between inhibitors and non-inhibitors and no correlation was observed between the parameters obtained from the software and the interactions observed.

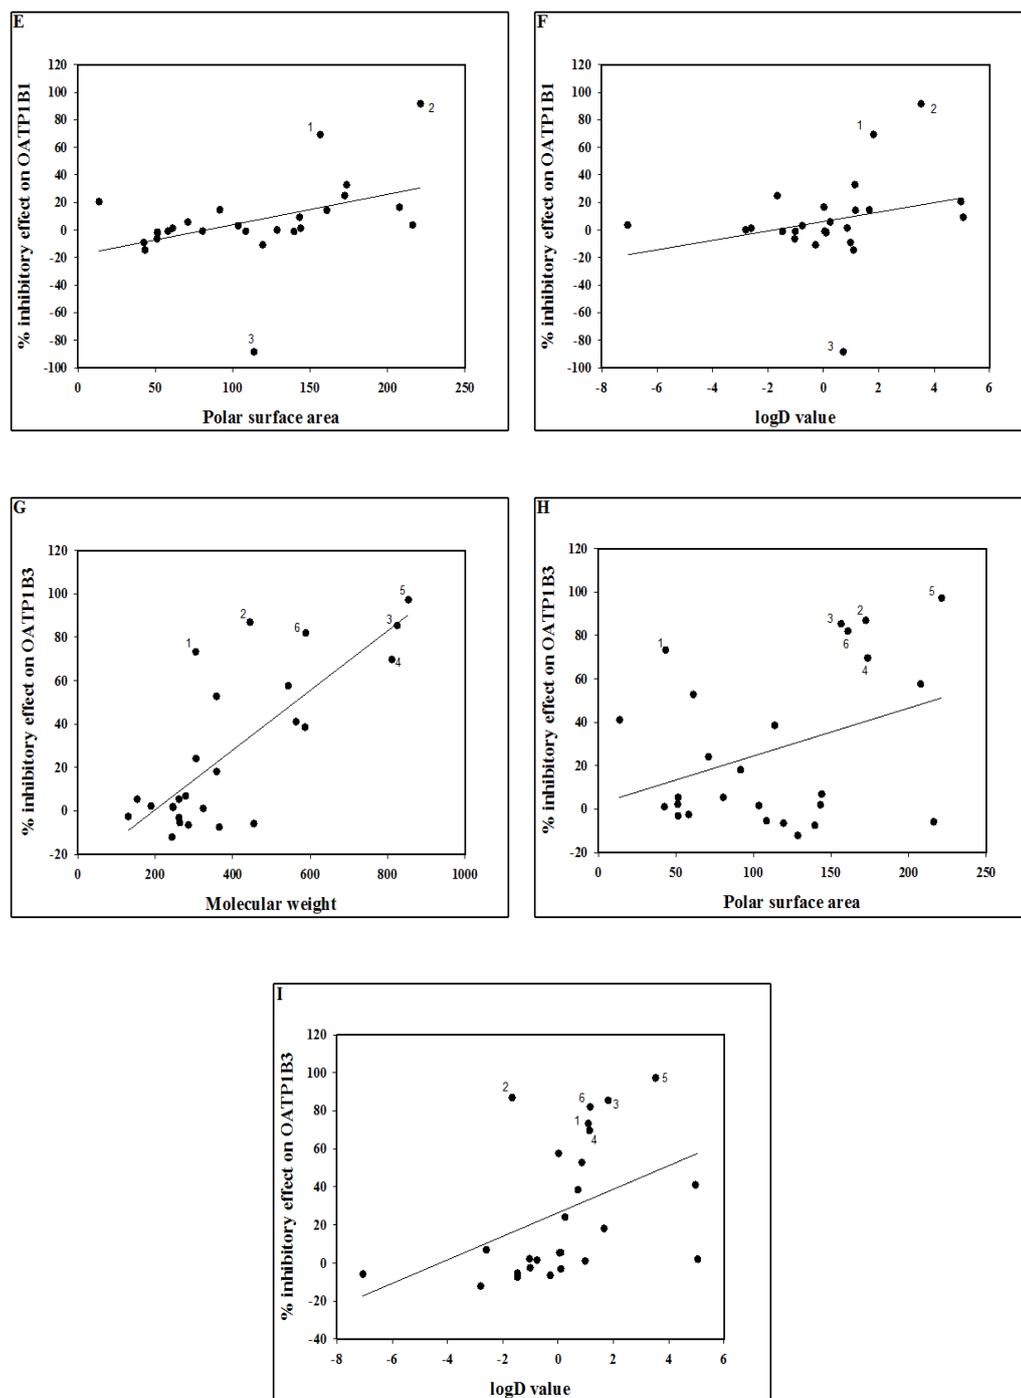

Figure 5.1 Correlation plots of inhibitory effect of antineoplastic compounds and their molecular parameters

Correlation plots of % inhibitory effect of OAT2 mediated cGMP uptake with molecular weights (A), polar surface area (at pH 7.4) (B), and logD value (at pH 7.4) of the antineoplastic compounds (C); 1, 2 and 3 represent bendamustine, irinotecan and paclitaxel, respectively;

OATP1B1 mediated ES uptake with molecular weights (D), polar surface area (at pH 7.4) (E), and logD value (at pH 7.4) of the antineoplastic compounds (F); 1, 2, and 3 represent vinblastine, paclitaxel and irinotecan, respectively; OATP1B3 mediated CCK-8 uptake with molecular weights (G), polar surface area (at pH 7.4) (H), and logD value (at pH 7.4) of the antineoplastic compounds; 1-chlorambucil, 2-mitoxantrone, 3-vinblastine, 4-vincristine, 5-paclitaxel, and 6-etoposide.

The other point to understand was whether the interactions observed lead to the uptake of these transporters, with a focus on OAT2. As paclitaxel has already been shown to be a substrate of OAT2 [12], we concentrated on the other two compounds, bendamustine and irinotecan.

5.1.1 Bendamustine is a substrate of organic anion transporter 2

As we saw an interaction between the OAT2 and the compounds, bendamustine, irinotecan and paclitaxel, we set out to find whether they are inhibitors alone or they can be transported by OAT2. Bendamustine is increasingly being recognized as the frontline therapy for chronic lymphocytic leukemia (CLL) [167-169] and also in the treatment of other lymphomas [170;171]. Structurally bendamustine contains alkylating and antimetabolite (purine analog) groups. It belongs to the nitrogen mustard group of molecules but its mode of action is predominantly as an alkylating agent, and the antimetabolite effect of this compound is not evident yet [172]. As far as we know, there is nothing known as to how bendamustine gains entry into the liver cells. Since we did not observe any interaction of OAT2 with chlorambucil which is very similar in structure to bendamustine or with any of the purine analogs tested, it is not possible with this data to conclude which functional group of bendamustine might be responsible for its interaction with OAT2. To find whether they are transported by OAT2, we focused on an

event that would occur if the antineoplastic drugs use the transporter protein to get into the cells, i.e. apoptosis. For measuring OAT2 mediated, bendamustine uptake induced apoptosis; we performed the caspase-3 assay wherein the OAT2 expressing cells treated with bendamustine showed an increase in the caspase-3 activity compared to the untreated OAT2 expressing cells and the control cells with or without treatment. The fact that the bendamustine induced increase in caspase-3 activity was diminished almost completely in the presence of probenecid demonstrates the specificity of this OAT2 mediated process. Similar experiments with irinotecan showed a high increase in apoptosis in pcDNA as well as OAT2 expressing cells with or without inhibitor, suggesting strong OAT2 independent accumulation of the compound in the conditions we used. This led us to believe that a protocol needs to be employed which allows the study with shorter incubation time.

5.1.2 Irinotecan is a substrate of organic anion transporter 2

Irinotecan, also referred to as CPT 11, is a water soluble derivative of camptothecin and a well-known topoisomerase inhibitor. It inhibits the topoisomerase I, an enzyme which relaxes DNA supercoils formed during the processes of DNA replication and transcription, leading to breaks in DNA that result in DNA fragmentation [32]. It is a common component of combination chemotherapeutic regimens that are in clinical trials for its efficacy in certain cancers like small cell lung cancer, colorectal cancer and pancreatic cancer [58;59;173]. There is little information as to how irinotecan is taken up into the cell. The active metabolite of irinotecan, SN-38, but not irinotecan as such, was shown to be a substrate for the transporter protein OATP1B1 [174]. In our experiments we found that it interacted strongly with OAT2, but not with NTCP. We employed HPLC analysis as it is highly sensitive and hence can detect irinotecan uptake even at lower

incubation periods, as described earlier [175]. A standard curve was developed for irinotecan as well as for the internal standard camptothecin and the observed amounts of irinotecan in the cell lysates were in the linear range of the curve. An interesting point to be noted is that, in our experiments, we did not find any peak for SN38, a hydrolysis product of irinotecan, which is the active metabolite of the compound mostly responsible for its *in vivo* activity. Accumulation of irinotecan was observed in both control cells and OAT2 expressing cells by HPLC analysis with fluorescence specific detection of irinotecan, suggesting a nonspecific accumulation in addition to the transporter mediated uptake. However, transporter mediated uptake exceeded the nonspecific accumulation of irinotecan in OAT2 expressing cells. This enabled us to determine the affinity (K_m) of OAT2 for irinotecan, which was determined to be 42.37 μM . In addition, co-incubation of irinotecan with 100 μM probenecid did not cause any inhibition on the OAT2 specific uptake of irinotecan. In parallel experiments, conducted by a colleague in the department, the K_i value of OAT2 for probenecid was determined to be 778.9 μM . This led us to believe that as we were working with shorter time periods, we needed a stronger inhibitor of OAT2 than probenecid to see a profound effect, and for this reason, we chose unlabeled cGMP, the model substrate of OAT2. Inhibition of the accumulation of irinotecan in the presence of cGMP in OAT2 expressing cells alone confirmed that this increase was transporter specific. This strongly suggests that irinotecan is a substrate of OAT2.

To conclude, the transporters OAT2, OATP1B1 and OATP1B3 interact with many of the antineoplastic compounds tested, and there exists a possibility of these transporters to contribute to the transporter mediated drug-drug interactions *in vivo*. As mentioned earlier, uptake transporters contribute at the initial stages of absorption, distribution, metabolism and excretion (ADME) of an exogenous compound. The uptake transporters

expressed in hepatocytes are especially important because liver is the center of xenobiotic metabolism. Although there is literature about many of the mechanisms involved in the activation of xenobiotic compounds, their interaction with efflux transporters, pathways of their excretion, it is not yet known how many of these compounds enter into the cells. The current study throws light on the possible roles played by the hepatic uptake transporters in the uptake of compounds found to interact with them. The contribution of these transporters to such interactions has to be verified in patients, wherein a complex network of transporter proteins works in tandem. However, such drug-drug interactions exert an influence on the combination chemotherapy of various cancers. Apart from the interactions with antineoplastic compounds, the regulation of expression of transporters also plays an essential role in the effectiveness of its interacting partner. This fact was evident from one of the earlier studies in the department, wherein the uptake of MPP was dependent on the level of expression of OCT3 in renal carcinoma cell lines [141].

5.2. Regulation of organic cation transporter 3 in renal carcinoma cells

In the above mentioned study focused on the expression of transporters in the renal carcinoma cell lines A498, ACHN, 786-O, RCCNG-1, and LN78, it was found that the organic cation transporter 3 (OCT3) was expressed at varying levels. While A498 had highest expression of OCT3 among the cell lines, ACHN had the least with 12 cycle difference in ΔC_t values. The difference between the uptake of the model substrate MPP between A498 and ACHN cells was comparable to that observed between OCT3 transfected Chinese Hamster Ovary (CHO) cells and mock CHO cells. The current study is aimed to decipher the possible reasons for this variable expression pattern of OCT3 in the renal carcinoma cells. As mentioned in section 1.10, some studies have been performed on the expression of OCT3 in other cell systems at the genetic, epigenetic,

transcriptional and post-translational levels in various model systems. In the current study, we looked at regulation of OCT3 at epigenetic and post-transcriptional levels.

5.2.1 Epigenetic regulation of OCT3 in renal carcinoma cells

A decrease in the expression of OCT3 in hepatocellular carcinoma compared to the tumor surrounding tissue was reported earlier [145]. Of the epigenetic mechanisms described in section 1.9.1, we looked at the impact of histone modification and DNA methylation on the expression of OCT3 in renal carcinoma cells. These two modifications play a major role in the regulation of gene expression as observed earlier [176]. While histone acetylation increases the transcriptional activity of a gene, histone deacetylation and DNA methylation reduce its expression. Inhibition of histone deacetylation has been shown to promote transcription of a gene. Treatment of cells with inhibitors of histone deacetylation was shown to increase the expression of transporters such as excitatory amino acid transporter 3 (EAAT3 or EAAC1) encoded by SLC1A1 [177].

In order to find out whether the high level of deacetylation of histones is the reason for the low expression of OCT3 in ACHN cells, we used valproic acid, an inhibitor of histone deacetylases. Treatment of ACHN cells with valproic acid did not change the expression level of OCT3 in them, suggesting that histone deacetylation is not the reason for the excessively low expression of OCT3 in ACHN cells. Similarly, hypermethylation of DNA hinders the transcription of DNA. 5-Aza-2'-deoxycytidine, also known as decitabine, is an inhibitor of DNA methyltransferase and treatment of cells with this compound was shown to restore the expression of monocarboxylate transporter 3 (MCT3) encoded by SLC16A8 [178]. To find out whether hypermethylation of DNA was the cause of low expression of OCT3 in ACHN cells, we treated the cells with 5-Aza-2'-deoxycytidine. Treatment of ACHN cells with 5-Aza-2'-deoxycytidine decreased the ΔCt

value by ca. two suggesting an increase of the expression of OCT3; however, this increase was not responsive to increasing concentrations of the compound. The increase observed does not explain the 12 cycle ΔC_t difference observed between A498 and ACHN cells. Apart from exerting external perturbations on the possible regulation mechanism, we also wanted to know whether the methylation levels of CpG residues in the promoter are responsible for this variable expression. To achieve this, we performed a next generation sequencing based on bisulfite conversion of unmethylated cytosines to uracil, referred to as Ion Torrent Sequencing.

5.2.2 Impact of methylation of promoter region on the expression of organic cation transporter 3.

Promoter methylation was previously shown to be responsible for the epigenetic down-regulation of the expression of the uptake transporter organic anion/carnitine transporter 2 (OCTN2) encoded by SLC22A5, in some cancer cell lines [87]. The down-regulation of OCT3 observed in hepatocellular carcinoma compared to the tumor surrounding tissue [145] was not due to any difference in the methylation status of the promoter region of OCT3 [179]. Methylation status of the promoter regions 1 and 2 of SLC22A3 gene in the four cell lines was determined using Ion Torrent sequencing technique. It was clear from the results that there was no substantial difference in the methylation patterns in the regions 1 and 2 of promoter of OCT3 gene in the CpG residues in the promoter among the four cell lines. However the methylation pattern of the positive control, human cortical renal epithelial cell pellet was markedly different and showed extensive hypomethylation in many of the CpG residues. This observation is in line with the observations of a previous study conducted on the promoter of OCT3 in hepatocellular carcinomas [179]. In addition, the expression of OCT3 in hepatocellular carcinoma was

not markedly different between the normal and tumor tissue, unlike what we observed comparing the RCCs with normal kidney cells. From the above results, it must be concluded that the epigenetic modifications tested, or the methylation status of promoter do not explain for the huge difference of expression of OCT3 between A498 and ACHN cells.

5.2.3 Investigation of microRNA dependent post-transcriptional regulation of organic cation transporter 3

MicroRNAs are being increasingly recognized as regulators of expression of a variety of genes and often engage in crosstalk between adjacent pathways. They were shown to regulate the expression of transporter proteins as well such as the SLC16A1 gene product, monocarboxylate transporter 1 (MCT1) [180]. MicroRNAs have been shown to alter the chemotherapeutic potential of antineoplastic compounds [181]. MicroRNAs are a group of non-coding RNAs that have been implicated in the regulation of many genes including transporters. As the binding of microRNA to its target messenger RNA was found to be with incomplete complementarity, programs were developed which use computational algorithms to predict possible targets of microRNA *in silico*. Using strong prediction algorithms, supported by correlation studies [117], a data set was generated from predicted species using various algorithms which predict microRNAs binding to 3' untranslated region of OCT3 mRNA, and consensus predictions were picked up for further analysis. The expression of 11 such microRNA species was obtained by qRT-PCR. While two of the microRNAs were not expressed quantifiably, there was a differential expression of the rest among the cell lines A498 and ACHN. Of these, the microRNAs hsa-mir-204 and hsa-mir-143 showed high expression in A498 cell line which had high OCT3 expression. This was against to what was expected as the expression of

microRNAs was supposed to be in inverse correlation with the expression of their targets. Interestingly, hsa-mir-204 was shown to increase the chemosensitivity of neuroblastoma cells to cisplatin [181]. However, it has been shown that cisplatin is transported by OCT1 and OCT2, but not by OCT3 [182]. On the other hand, it was shown to be at least partially responsible for cisplatin uptake in human cervical cancer cells [183]. In addition, microRNA 204 was implicated as a tumor suppressor [184;185] and maintenance of epithelial physiology [186]. Similarly, microRNA 143 was also reported to be a tumor suppressor [187;188]. MicroRNA 143 was implicated in conferring chemosensitivity on colorectal cancers to oxaliplatin. Although the target was established, the mechanism of increase of chemosensitivity has not been explained [189]. It is worthwhile to mention here that oxaliplatin was shown to be transported by OCT3 [182].

The impact of these two microRNAs on the expression of OCT3 was tested by experiments which involved altering the levels of microRNA. This was achieved by transient transfection of miRNA mimics and antimirs into the cells and any change in the expression of OCT3 was monitored by qRT-PCR. However, this approach did not work as there was no correlation found between the expression levels of microRNAs and OCT3. This prompted us to look to other strategies for finding out potential microRNAs that could regulate the expression of OCT3, one of which was genome wide analysis of microRNA expression. Novel techniques which make the study of genome wide expression of microRNAs possible have been recently developed. One such technique, the next generation sequencing analysis of genome wide expressed microRNAs was performed in the DNA microarray and deep sequencing facility in the university. The results were quite encouraging as a lot of microRNA species were found distributed among the four cell lines with highly variable expression (ca. 10 cycles). Although there are a lot of studies conducted on expression profiling of microRNAs in renal cell

carcinoma and the impact of microRNAs on expression of transporters such as the glucose transporter 1 (GLUT1) [190], none of them so far were correlated to OCT3 expression. The genome wide expression analysis we conducted revealed different levels of expression of mir-204 and mir-143 compared to our initial observations. This led us to believe that a correlation study between the microRNA expression and mRNA expression from the same samples would give us more accurate details about the interactions in these cells as performed earlier [191]. This is an emerging trend in microRNA research with the development of databases such as MIMA (microRNA and mRNA integrated analysis). Accordingly, genome wide mRNA analysis is also being performed. Correlation of transcriptome analysis with the microRNA data obtained from the samples is the way forward to look at candidate genes and microRNAs involved in the regulation of expression of OCT3. The entire data shall be correlated with data obtained from healthy kidney cells; this approach would help us to look at factors that might regulate the expression of OCT3 at the transcriptional as well as post-transcriptional levels.

6. Summary and conclusions

To summarize, we report novel interactions of the SLC transporter proteins expressed in liver. Organic anion transporter 2 interacted with the antineoplastic compounds bendamustine, irinotecan and paclitaxel. Furthermore, we proved that OAT2 can act as transporter for bendamustine and irinotecan. This is a very important observation as this is the first report which shows an uptake transporter for bendamustine and irinotecan. Irinotecan is metabolized into SN38, which was shown to be a substrate of OATP1B1; however, how irinotecan enters the cells is still a question, and our observation of OAT2 being able to transport irinotecan might provide an answer to this puzzle. We report that OATP1B1 interacts strongly with vinblastine and paclitaxel. In addition, OATP1B3 interacted with the compounds chlorambucil, mitoxantrone, vinblastine, vincristine, paclitaxel and etoposide. Other than paclitaxel, it remains to be seen whether these compounds are transported by OATP1B1 and OATP1B3. We attempted to understand the basis of the differentiation of compounds that interact with those which do not interact with the transporter proteins. However, we did not find any correlation between the molecular parameters such as molecular weight, polar surface area, logP and logD values and the fact whether they interact with a protein or not. From the IC₅₀ values generated, we predict whether these interactions might lead to potential drug-drug interactions and as per the calculations, the interactions of irinotecan with OAT2, paclitaxel with OATP1B1, and the compounds mitoxantrone, paclitaxel and etoposide with OATP1B3 have the potential to cause drug-drug interactions and this needs to be looked into in *in vivo* situations. Considering the fact that cancerous tissues exhibit a differential expression of transporter proteins, as reported in many cases, the expression of these transporters in various cancers also needs to be evaluated. This has the potential to increase the chances of a successful chemotherapy many fold. In addition, we also looked at the causes of a

variable pattern of expression of OCT3 in the renal carcinoma cell lines A498, ACHN, 786-O, and LN78, a study reported earlier by our group. We used compounds which essentially perturbed the DNA methylation and histone deacetylation mechanisms independently, and analyzed their effects on changes of expression of OCT3. We observed that these mechanisms could not account for the huge difference of expression of OCT3 in A498 (a high OCT3 expressing cell line) and ACHN (a low OCT3 expressing cell line). Methylation status of the promoter region of OCT3 was also analyzed and no differences were observed among the four RCCs. Using prediction algorithms that predict microRNAs able to bind to 3' UTR of OCT3, we selected those microRNAs which were predicted by at least a couple of accurate prediction programs, as reported in the literature. The expression of these microRNAs was evaluated in the cell lines A498 and ACHN and two microRNAs hsa-mir-204 and hsa-mir-143 were found to be expressed more in A498, a cell line with high OCT3 expression. Altering the levels of these microRNAs did not affect the expression of OCT3 suggesting that they are not involved in the regulation of OCT3. We broadened our search by performing a genome wide microRNA analysis in the four RCCs. Many microRNAs are found to be differentially expressed in these cell lines and a correlation between the microRNA expression data with the transcriptome data is to be done. In this direction, the transcriptome analysis is being performed. This strategy shall also shed light on those microRNAs which are targeting OCT3 indirectly, along with transcriptional regulators of OCT3.

To conclude, this study demonstrates for the first time, OAT2 as an uptake transporter for bendamustine and irinotecan, antineoplastic compounds widely used in cancer chemotherapy. In addition, novel interactions of the antineoplastic compounds with OATP1B1 and OATP1B3 are reported. Furthermore, the epigenetic mechanisms of histone deacetylation, DNA methylation, and differences in methylation status of CpG

residues in the promoter region of OCT3 were not responsible for the differential expression of OCT3 in A498 and ACHN cells. A comprehensive approach of next generation sequencing of mRNAs of the cell lines is being performed, which in addition to the expression data obtained for microRNAs, would be crucial to decipher the regulators of OCT3 in renal carcinoma cells.

8. Curriculum Vitae

Venkata Vishnu Vardhan Reddy Marada

Born 28th October, 1982 in Visakhapatnam, India

Email: venkata.marada@med.uni-goettingen.de

Education and research

2011-present.....PhD student at the institute of systemic physiology and pathophysiology, University medical Centre (PhD program Molecular Medicine)

PhD thesis: "Regulation of expression of SLC transporter family of proteins and their interaction with antineoplastic compounds"

2010.....Research assistant in the department of gastroenterology, hepatology and endocrinology, Hannover medical school, Hannover.

2006-2010.....Researcher in the department of biochemistry, Indian institute of science.

2004-2006.....Masters in biochemistry at the University of Hyderabad, India.

Presentations

May 2012 Poster presentation at the Bad Herrenalber Transporter- und Barriere- Tage, Bad Herrenalb, Germany

October 2012,

November 2013 Oral presentations in Göttinger transporttage, Göttingen
