# Design, Synthesis and Applications of new cationic ligands of the $15^{\text {th }}$ main group elements 

Dissertation

# zur Erlangung des mathematisch-naturwissenschaftlichen Doktorgrades "Doctor rerum naturalium" der Georg-August-Universität Göttingen im Promotionsprogramm Chemie der Georg-August University School of Science (GAUSS) 

vorgelegt von
Hendrik Tinnermann
aus Ahlen

Göttingen, 2017

## Betreuungsausschuss:

Prof. Dr. Manuel Alcarazo (Institut für Organische und Biomolekulare Chemie, Tammannstr. 2, 37077 Göttingen)

Prof. Dr. Dietmar Stalke (Institut für Anorganische Chemie, Tammannstr. 4, 37077 Göttingen)

## Mitglieder der Prüfungskommission:

Referent: Prof. Dr. Manuel Alcarazo (Institut für Organische und Biomolekulare Chemie, Tammannstr. 2, 37077 Göttingen)

Korreferent: Prof. Dr. Dietmar Stalke (Institut für Anorganische Chemie, Tammannstr. 4, 37077 Göttingen)

## Weitere Mitglieder der Prüfungskommission:

Prof. Dr. Franc Meyer (Institut für Anorganische Chemie, Tammannstr. 4, 37077 Göttingen)

Prof. Dr. Sven Schneider (Institut für Anorganische Chemie, Tammannstr. 4, 37077 Göttingen)

Dr. Shoubhik Das (Institut für Organische und Biomolekulare Chemie, Tammannstr. 2, 37077 Göttingen)
Dr. Franziska Thomas (Institut für Organische und Biomolekulare Chemie, Tammannstr. 2, 37077 Göttingen)

Hiermit versichere ich, dass ich die eingereichte Dissertation selbständig erfasst und keine anderen als die angegebenen Quellen und Hilfsmittel benutzt, sowie Zitate kenntlich gemacht habe.

Die vorliegende Arbeit entstand unter Anleitung von Herrn. Prof. Dr. Manuel Alcarazo in der Zeit von November 2012 bis Dezember 2015 am Max-Planck-Institut für Kohlenforschung in Mülheim an der Ruhr und in der Zeit von Januar 2016 bis September 2016 an der Georg-August-Universität zu Göttingen. Diese Arbeit wurde in folgenden Beiträgen veröffentlicht:
H. Tinnermann, C. Wille, M. Alcarazo, Angew. Chem. Int. Ed. 2014, 33, 8732.
E. Haldón, Á. Kozma, H. Tinnermann, L. Gu, R. Goddard, M. Alcarazo, Dalton Trans. 2016, 45, 1872.
~ für meine Eltern ~ Danke für die Unterstützung und die Geduld in allen Lebenslagen

## Danksagung

Mein herzlichster Dank gilt Prof. Dr. Manuel Alcarazo für die Aufnahme in seinen Arbeitskreis und die Vergabe des interessanten Promotionsthemas. Des Weiteren danke ich Prof. Manuel Alcarazo für seine große Hilfe, die mir erlaubte mich sowohl auf fachlicher und persönlicher Ebene stark zu entwickeln. Ich bin zutiefst dankbar für all die Motivation zu der Prof. Dr. Manuel Alcarazo angeregt hat, sowie für seine kompetente Beratung. Herrn Prof. Dr. Manuel Alcarazo und Herrn Prof. Dr. Dietmar Stalke danke ich für die freundliche Übernahme des Referats und Koreferats.
Weiterhin möchte ich der Max-Planck-Gesellschaft und im Besonderen dem Max-PlanckInstitut für Kohlenforschung, sowie der Georg-August Universität zu Göttingen für die Bereitstellung meines Arbeitsplatzes und die finanzielle Unterstützung danken.
Allen Mitgliedern der Arbeitsgruppen Fürstner und Alcarazo danke ich für die gute Zusammenarbeit, das angenehme Arbeitsklima und die schönen Stunden innerhalb und außerhalb des Laboralltags. In den vielen gemeinsam verbrachten Laborstunden seid Ihr mir alle ans Herz gewachsen, vielen Dank dafür. Für die in Mülheim verbrachte Zeit möchte ich mich besonders bei Sigrid Holle, Gerlinde Mehler, Agnes Kozma, Elisa Gonzales, Christian Wille und Angus Rocha für die großartige Arbeitsatmosphäre sowie für Ihre Hilfsbereitschaft bedanken. Für die große Hilfe bei organisatorischen Angelegenheiten danke ich recht herzlich Frau Lickfeld. Für die in Göttingen verbrachte Zeit möchte ich mich besonders bei Kai Averesch und Katja Grube aus meinem Labor sowie allen weiteren Mitgliedern der Arbeitsgruppe bedanken. Mein Dank geht an die Mitarbeiter aller analytischen Abteilungen für die zuverlässige und schnelle Durchführung und Auswertung zahlreicher Analysen. Besonders bedanke ich mich bei Herrn Kochius, Herrn Dr. Farès aus der NMR-Abteilung, bei Herrn Kampen, Frau Blumenthal und Herrn Klein aus der MS-Abteilung. Prof. Dr. Christian W. Lehmann, Dr. Richard Goddard, Jörg Rust, Nils Nöthling, Herrn Dr. Mondal, Frau Dreier, Frau Schucht und Frau Dreher aus der Kristallographie-Abteilung möchte ich besonders für die herzliche und angenehme Atmosphäre während meines Aufenthalts danken. Mein Dank geht an die Mitarbeiter der theoretischen Abteilung für die gute Berechnung und hilfreichen Informationen zur Aufklärung der Mechanismen. Besonders bedanke ich mich bei Dr. Yiying Zheng und Prof. Walter Thiel. Für umfangreiche Cyclovoltammetrie- Messungen möchte ich mich des Weiteren bei Herrn Christian Wille und Herrn Leo Nicholls aus der Arbeitsgruppe Alcarazo bedanken.

Für das gründliche Korrekturlesen danke ich Prof. Manuel Alcarazo, Dr. Christophe Werlé und Kai Averesch. Ich möchte allen Freunde besonders für die gemeinsam verbrachte Zeit in Mülheim und in Göttingen danken. Auch möchte ich mich bei meiner Familie für die Unterstützung in allen Lebenslagen bedanken.

We are indeed a blind race, and the next generation, blind to its own blindness, will be amazed at ours.

## 1. The importance of ligand design in catalysis

Ligands significantly alter the properties of the metals they coordinate. Therefore, ligand design can have an enormous impact on the selectivity and reactivity of a given transformation and consequently, has found broad applications in the synthesis of new molecules and materials. The design of new ligand structures and their applications in metal catalysis can even enable completely new reactivities or selectivities. Amongst other prominent examples are the Grubbs catalysts for olefin metathesis, awarded with the Nobel Prize in 2005 (together with Schrock and Chauvin). ${ }^{1}$

The Grubbs catalysts are a great example of the importance of ligand design in catalysis. While the first well defined Grubbs catalyst was prepared 1992 from $R u \mathrm{Rl}_{2}\left(\mathrm{PPh}_{3}\right)_{4}$ and diphenylcyclopropene, its low accessibility limited its use. ${ }^{2}$ Therefore, the first generation Grubbs ${ }^{3}$ catalyst $\mathbf{1}$ has been developed that is accessible in an easy one pot synthesis starting from $\mathrm{RuCl}_{2}\left(\mathrm{PPh}_{3}\right)_{4}$, phenyldiazomethane and tricyclohexylphosphine. This catalyst is already highly stable towards air and compatible with a broad range of functional group. However, due to the low life time of the catalyst ring closing reaction for larger ring sizes only limited conversions were observed. ${ }^{4}$ Therefore Grubbs further exploited ligand design to accelerate the activation of the catalyst that proceeds via dissociation of one phosphine moiety. Substituting one phosphine with a cyclic bis-amino carbene ligand increased the dissociation rate of the remaining phosphine unit and therefore the metathesis activity, leading to the nowadays most used metathesis catalyst $\mathbf{2}^{5}$

1
1st generation catalyst Grubbs, 1995

2nd generation catalyst
Grubbs, 1999

Scheme 1: ligand designs by Grubbs.
This pronounced effect of ligand design - here shown with the development of Grubbs $2^{\text {nd }}$ generation catalyst - towards the reactivity and selectivity of any metal catalysed reaction fostered the development of a broad range of different ligand classes as well as many

[^0]variations within the ligand class. Nowadays a number of ligands have been developed, outstanding examples being the ligand design of carbenes and of phosphines.

### 1.1 Utility of phosphines in ligand design

The phosphines advanced as a ligand class of high importance, because they can easily be prepared and modulated. This modularity allows the ligands to control the steric and electronic properties of the metals they coordinate, therefore, enabling control over selectivities and yields of a vast number of different transformations. One of the most common examples of phosphines being the triphenylphosphine, which is applied in all fields of catalysis for example in $\pi$-acid catalysis as well as in cross coupling reactions. Another positive aspect that proved beneficial from a synthetic point of view was the possibility to examine the phosphines by simple ${ }^{31} \mathrm{P}$ NMR to ensure any modifications made. Phosphines obviously allow to be tuned in their electronic and steric parameters and this high modularity has been used to optimize the ligands in several processes, either to increase or to deplete the electron density of the metal or to modulate its steric environment.

Prominent examples are amongst others:

- Xantphos (2) ${ }^{6}$, ensuring a coordination mode between cis and trans,
- Buchwald's ligands,(e.g. SPhos 3), highly efficient in palladium catalysed aminations,
- BINAP (4) ${ }^{7}$, used by Noyori as catalyst for asymmetric hydrogenations, and
- TPPTS (5), ${ }^{8}$ used for hydroformylation in the Ruhrchemie/Rhône-Poulenc-process.

[^1]

4, BINAP

3, SPhos

5, TPPTS

Scheme 2: prominent phosphines.
The possibility to tune the stereo electronic properties of phosphines increases their importance and utility in a number of transformations: For example if ligands with high $\pi$ accepting properties are needed, instead of phosphines, phosphite or polyfluorinated phosphines can be used to improve yields and selectivities. For example Toste et al. ${ }^{9}$ reported the use of a phosphite ligands in a highly selective Au-catalysed [4+2] cycloaddition in excellent yields. The enhanced $\pi$-accepting properties of the phosphite decrease the stability of the carbocation intermediate $\mathbf{A}$ of the competing [4+3] cycloaddition, therefore improving the selectivity (100:0) and the yield (91\%) of the [4+2] process.

Scheme 3: competing pathways of the gold catalysed cycloaddition reported by Toste.

[^2]Obviously, the electronic structure of the employed phosphine can as well be tuned to be more $\sigma$-donating. Formal substitution of the phenyl groups of triphenylphosphine with tertbutyl groups leads to tris(tertbutyl)phosphine, a highly $\sigma$-donating ligand.

Miyaura et al. ${ }^{10}$ reported a large accelerating effect in the rhodium catalysed addition of aryl boronic acids to aldehydes using tris(tertbutyl)phosphine as ligand. Increasing the $\sigma$-donor properties of the used phosphine, - from triphenylphosphine over tricyclohexylphosphine to tris(tertbutyl)phosphine - improved the yields of the rhodium catalysed additions at $50^{\circ} \mathrm{C}$ from $33 \%$ over $50 \%$ to full conversion. Tris(tertbutyl)phosphine was even reactive enough to achieve full conversion at room temperature.

Scheme 4: rhodium catalysed addition of phenylboronic acid to 4-methoxybenzaldehyd.
Steric parameters also significantly modulate the reactivity of the catalyst. As mentioned before, tris(tertbutyl)phosphine is particular successful in reactions, in which high $\sigma$-donor capabilities are needed. One prominent example being palladium catalysed cross coupling reactions, in which the steric bulk of tris(tertbutyl)phosphine ensures a di-ligation of the palladium centre, avoiding, or at least slowing down, its deactivation. ${ }^{11}$

For bidentate ligands besides the steric and electronic parameters, the bite angle is of tremendous importance. Among others, Keim et al. ${ }^{12}$ showed an enormous effect for the hydrocyanation of styrene (8) after optimisation of the bite angle of the employed ligands. For this particular transformation an optimal bite angle around 104 to $105^{\circ}$ was found, ensuring high yields and selectivity of the desired hydrocyanated product, while only small changes in the bite angle significantly reduced the yield of the desired product. The authors conclude that the bite angle of $105^{\circ}$ forces the nickel catalyst to adopt a tetrahedral geometry, beneficial for the reductive elimination, underlining the importance of ligand design.

[^3]

| Ligand | Bite angle [ ${ }^{\circ}$ ] | Yield [\%] |
| :---: | :---: | :---: |
| $\left.\mathrm{Ph}_{2} \mathrm{P}\left(\mathrm{CH}_{2}\right)_{2}\right) \mathrm{PPh}_{2}$ | 78 | 1 |
| BINAP | 85 | 4 |
| $\left.\mathrm{Ph}_{2} \mathrm{P}\left(\mathrm{CH}_{2}\right)_{3}\right) \mathrm{PPh}_{2}$ | 87 | 7,5 |
| $\left.\mathrm{Ph}_{2} \mathrm{P}\left(\mathrm{CH}_{2}\right)_{4}\right) \mathrm{PPh}_{2}$ | 98 | 5,5 |
| DPEPhos | 101 | 38 |
| SiXantPhos | 105 | 94,5 |
| ThiXantphos | 106 | 80,5 |
| Xantphos | 109 | 51 |
| DBFPhos | 131 | 0,7 |

Scheme 5: effect of the bite angle of the employed ligand on the yield of the hydrocyanation of styrene.
The possibility to modulate the solubility was as well investigated, with the most famous example being the Ruhrchemie/Rhône-Poulenc-process mentioned before. Here the phosphine is modified by the introduction of three sulfonate groups to be highly soluble in an aqueous phase ( $>1 \mathrm{~kg} / \mathrm{l}$ ) and insoluble in the organic product phase. ${ }^{8}$ This allows easy recovery of the catalyst just by separation of two phases. TPPTS is applied since 1984 in the rhodium catalysed hydroformylation of propene (10) in the Ruhrchemie/Rhône-Poulenc process on a multi-ton scale.

Scheme 6: Ruhrchemie/Rhône-Poulenc process.
This concept then was first extended to systems based on fluorous biphasic hydroformylations. ${ }^{13}$ While at lower temperatures hydrocarbons and fluorocarbons form two phases, they mix at higher temperatures. This allows reactions to perform in one phase at high temperatures and at the same time allowing easy catalyst. While the fluorination alters the electronic and steric parameters of the employed phosphine as well, the main focus of this section lies within the changed solubility. Gladysz et al. ${ }^{14}$ reported the applications of an analogous fluorous phosphine in the Morita-Baylis-Hillman reaction. This catalyst due to its lowered solubility in hydrocarbons (not soluble at rt, soluble at $60^{\circ} \mathrm{C}$ ) could be recycled up to 5 times without significant loss of reactivity.

Scheme 7: Morita-Baylis-Hillman reaction employing fluorous phosphine.
Despite the high success of phosphines in catalysis alternative ligand systems have been developed as well, for example carbenes. These ligands classically possess a singlet state at the central carbon atom, which is stabilized through the p-orbitals of the neighbouring atoms usually being nitrogen. This results in a high net electron density on the central carbon atom. This atom donates electron density to the metal via $\sigma$ - and $\pi$-donation. While only little backdonation from the metal towards the carbenes occurs.

The steric parameters of carbenes and phosphines are largely different. While phosphines usually bend away from the metal, the carbene substituents form a pocket around it. ${ }^{15}$ This orientation enables NHCs to perform with remarkable selectivity in asymmetric catalysis as the stereo information is brought closer to the reactive centre (figure 1 ).

[^4]

Figure 1: shape of phosphines and NHCs. ${ }^{15}$
Early evidence of the existence of carbenes was proposed 1957 by Breslow ${ }^{16}$ for the catalytic cycle of vitamin B1 transforming furoin (21) from furfural (16) (scheme 8). He based his hypothesis on an experimental fact: when the reaction was performed in deuterated water, instead of a proton at the $\mathrm{C}_{2}$ position a statistical mixture of hydrogen and deuterium was found, indicating the presence of a deprotonated species - the carbene 15.

16
Scheme 8: generation of furoin proposed by Breslow based on the formation of a carbene.

[^5]The first isolated carbene phosphinocarbene 22 was prepared by Bertrand ${ }^{17}$ in 1988 and as no solid state structure was obtained the carbenic nature was initially doubted. The first structural proof has been achieved by Arduengo ${ }^{18}$ in 1991 preparing diaminocarbene 23.

Bertrand:

23, NHC

15, proposed intermediate

Scheme 9: proposed and synthesized carbenic structures.
Carbenes from their discovery on have been applied extensively as ligands in metal catalysis and several new processes based on carbenes have been developed. Important examples include NHC palladium complexes ${ }^{19}$ like 24 used in Suzuki-Miyaura ${ }^{20}$, Negishi ${ }^{21}$, Sonogashira ${ }^{22}$ or Heck-Mizoroki ${ }^{23}$ couplings and the Hoveyda-Grubbs catalyst 25 used in alkene metathesis, even incorporating a NHC and a phosphine.

24

25

Scheme 10: NHC palladium complex 24 and Hoveyda-Grubbs catalyst 25.
Realizing the advantages of carbene and phosphine ligand systems one can easily realise, that both systems are complementary. For instance, the already discussed Tolman electronic parameter (TEP) and the average CO stretching frequencies of NHCs and phosphines can be compared. Where extreme $\sigma$-donating ligands are needed only few electron rich phosphines

[^6]are available, but his lack of $\sigma$-donation can be achieved by carbenes. ${ }^{24}$ This fostered the coexistence of phosphines and NHCs as important ligand classes in all fields of catalysis.

Scheme 11: Tolman electronic parameter (TEP) versus the average CO stretching frequencies for NHCs and phosphines. ${ }^{24}$

## 2. Ligand design in $\pi$-acid catalysis

### 2.1 Generalities, mechanism and scope

$\pi$ - acid catalysis evolved in the last years to a highly active area of research in organometallic chemistry. $\pi$ - acids selectively bind to unsaturated C-C double and triple bonds allowing powerful and atom-economic transformations to obtain complex products form rather simple starting material.

In general $\pi$-acid catalysed reactions consist of an activation step, coordination of the substrate, nucleophilic attack and protodemetalation. ${ }^{25}$

After activation of a suitable metal precursor, the catalytically reactive species is generated (here: $[A u]^{+}$). The activated metal centre is then coordinated by a $\pi$-system, generally, an alkene or alkyne, which upon coordination following the Dewar-Chatt-Duncanson model (see next page) is activated towards the following nucleophilic attack leading to a metal alkyl/vinyl intermediate. Upon protodemetalation the product of the hydrofunctionalisation is realised and the reactive metal species regenerated. Besides productive pathways catalyst deactivation can occur generating metal ${ }^{0}$ and bisligated metal ${ }^{+}$, furthermore geminal digold formation for gold catalysis might as well lead to a resting state of the catalyst.

[^7]

Scheme 12: $\pi$-acid catalysis: simplified catalytic cycle of a gold catalysed hydrofunctionalisation.
The unique reactivity of these metals in catalysis can be explained considering the interaction between the metal centre and the associated $\pi$-system. This interaction consists of $\sigma$-donation of the $\pi$-systems (for example an alkyne) towards an empty d - or s -orbital of the metal and of $\pi$-backdonation from a full d- orbital of the metal towards the empty $\pi^{\star}$-orbital of the $\pi$-system. For example for alkynes this results in a neat reduction of electron density of the $\pi$-system enhancing its reactivity towards nucleophiles, while at the same time owed to the $\pi$ backbonding, the bond order of the $\pi$-system decreases.

Scheme 13: schematic representation of the Dewar-Chatt-Duncanson model.

The model to describe these interaction was first reported by Dewar et al. ${ }^{26}$ in 1951 and expanded by Chatt and Duncanson ${ }^{27}$ in 1953 on the basis of olefin coordination towards platinum and is therefore named the Dewar-Chatt-Duncanson model. Due to the high amount of backbonding and the resulting weakening of the bond order a bending of the idealized geometry of a $\pi$-complex can as well be understood as a metallacyclopropane. However Hoffmann et al..$^{28}$ showed in 1979 that the real bonding situation lies between these two forms.

Scheme 14: extreme resonance forms of alkene metal complexes.
The first alkene metal structure - the well-known Zeise's salt $\left[\mathrm{PtCl}_{3}\left(\mathrm{C}_{2} \mathrm{H}_{4}\right)\right]$ - which was already prepared in $1827^{29}$ (even though the solid state structure was only implied in $1954^{30}$ and verified in $1970^{31}$ ), evidences the presence of the before mentioned interactions. Although the alkene bond is only marginally elongated to $1.37 \AA \AA$ compared to $1.35 \AA \AA$ in free ethylene.

Scheme 15: solid state structure of the anion in Zeise's salt.
The first structural evidence of a gold alkyne interaction was reported by Dias et al. ${ }^{32}$ in 3hexyne gold chloride complexes. As mentioned before the $\sigma$-donation of the alkyne towards the metal and the $\pi$-backbonding result in a bending of the idealized linear geometry of an

[^8]uncoordinated alkyne $\left(180^{\circ}\right)$ towards a metallacyclopropene structure $\left(120^{\circ}\right)$, resulting in bond angles of $167^{\circ}$ and $163^{\circ}$.

Scheme 16: solid state structure of 3-hexyne gold chloride complex.
In the gold complex reported by Fürstner ${ }^{33}$ this concept was extended to catalytically applied NHC gold cyclododecyne complexes.

Scheme 17: solid state structures of free cyclododecyne and the NHC gold cyclododecyne complex 27.

The coordinated alkyne shows significant bending away from $175.9^{\circ}$ in free cyclododecyne to an average bond angle of $168^{\circ}$ in the NHC gold dodecyne complex 27 underlining the importance of the interactions between gold and $\pi$-systems for catalysis. This trend is also

[^9]observed in the carbon NMR shifts of the alkyne: While in free cyclododecyne the alkyne signal is at 81.7 ppm , in the coordinated complexes the alkyne carbon is shifted significantly down field in complexed cyclododecyne gold chloride $\mathbf{2 6}$ ( 86.4 ppm ) and in gold NHC complex 27 (88.0 ppm).

| Compound | 攵 $[\mathrm{ppm}]$ in $\mathrm{CD}_{2} \mathrm{Cl}_{2}$ |
| :---: | :---: |
| cyclododecyne | 81.7 |
| $\mathbf{2 6}$ | 86.4 |
| $\mathbf{2 7}$ | 88.0 |

Table 1: carbon NMR shifts of cyclododecyne and its corresponding gold complexes 26 and 27.

26

27

Scheme 18: alkyne complexes $x$ and $x$ prepared by Fürstner et al.
This interaction renders then the nucleophilic attack to occur easier, generating the aforementioned metal alkyl/vinyl intermediates. The nucleophilic attack itself is highly sensitive towards the nature of the counter anion. ${ }^{34}$ Two major catalyst deactivation pathways can occur depending on the nature of the anion. Strongly coordinating anions can decoordinate the alkyne and regenerate the precursors or eventually form a tricoordinated complex 30, while strongly basic counter anions can deprotonate the nucleophile (here methanol) and thereby form a catalytically inactive gold nucleophile adduct 29.

Scheme 19: catalyst deactivation steps during the nucleophilic attack.
Besides the later on discussed ligand effect in the protodemetalation step, the effect of substrate substituents should be considered as well. While in general the protodemetalation is considered fast, specific substitution pattern may slow down the rate of this elementary step. Theoretical studies by Ariafard et al. ${ }^{35}$ showed that for the protonolysis of alkenyl complexes

[^10]31. The reaction rate is mainly dependent of the substitution pattern and of the ligand within the same substitution pattern. The stronger the Au carbon bond is, the higher the activation barrier will be. Therefore protodemetalation is faster, when $\pi$-donating substituents (e.g. OMe ) are present, while protodemetalation is significantly slower, when $\pi$-accepting substituents (e.g. -CN) are present.

Scheme 20: theoretical investigation of the substitution effect for the protodeauration step in $\pi$-acid catalysis.
The counter anion plays a major role in the protodemetalation step as well, because it greatly lowers the activation barrier of this elementary reaction acting as a proton shuttle. Belanzoni et al. ${ }^{34}$ calculated the proton migration step in the alkoxylation of alkynes to be highly depended of the counter anion. Much lower activation energies were calculated for $\mathrm{BF}_{4}{ }^{-}$or OTf assisted protodemetalation ( $2.4 \mathrm{kcal} / \mathrm{mol}$ for $\mathrm{BF}_{4}^{-}$and $4.7 \mathrm{kcal} / \mathrm{mol}$ for $\mathrm{OTs}^{-}$) in comparison to the protodemetalation without an anion ( $11.0 \mathrm{kcal} / \mathrm{mol}$ ).
$\pi$-acid catalysis has found extensive applications in chemistry. A few noteworthy examples include for gold and platinum catalysis enine cyclisations, ${ }^{36,37}$ cycloadditions, ${ }^{38,39}$ hydroadditions, ${ }^{40,41}$ Meyer-Schuster-rearrangement ${ }^{42,43}$ and applications in natural product synthesis. ${ }^{44,45}$

[^11]
### 2.2 Influence of the ancillary ligand in $\pi$-acid catalysis

The ancillary ligand significantly controls the reactivity and selectivity as well as the rate of a chosen transformation. While the electronic properties possess a strong influence towards the reactivity and selectivity of the corresponding reaction, in many cases and especially for the Buchwald type ligands the rate of the reaction is as well modulated by the stability of the catalyst. Bulkier ligand can lead to a better steric shielding of the metal centre, therefore stabilizing the complexes and slowing down decomposition reactions.

The electronic properties of the ancillary ligands strongly influences the rate of the nucleophilic attack and of the protodemetalation. In $\pi$-acid catalysis weak $\sigma$-donor and good $\pi$-acceptor ligands reduce the electron density of the metal and therefore, a coordinated alkyne donates more electron density towards the metal resulting in a higher partial positive charge, promoting the nucleophilic attack. This, at the same time slows down the rate of the protodemetalation, as the metal with a good $\pi$-accepting ligand already is rather electron poor. On the other hand if a good $\sigma$-donor is used, the rate of the nucleophilic attack is reduced, as the metal backdonates more electron density towards the alkyne, at the same time accelerating the rate of the protodemetalation.

The electronic and steric effects of ligands in Au-catalysis have been studied by Xu et al. ${ }^{46}$ amongst others. They showed that proper ligand design can lead to increased reaction rates if the rate determining step and the rate of catalyst deactivation are considered.

If the activation of the alkyne, alkene or allene towards nucleophilic attack is the rate determining step, strong electrophilic activation of the metal should enhance the reaction rate. Employing a weak nucleophile, like electron poor hydrazides and utilizing less electrophilic $\pi$ systems like allenes, the rate determining step would become the nucleophilic attack. This low reaction rate then could be enhanced by the use of electron poor phosphine ligands, which would generate a more $\pi$-acidic metal, resulting in a stronger activation of the $\pi$-system and a higher overall reaction rate.

Toste et al. ${ }^{47}$ showed that for the intermolecular hydroamination of allene $\mathbf{3 4}$ the rate determining step is the activation of the allene towards nucleophilic attack and therefore the use of an electron poor ligand ( $p-\mathrm{CF}_{3}$ substituted $\mathrm{PPh}_{3}$ ) leads to a 10 -fold increase in reaction rate compared to classical triphenylphosphine.

[^12]
34
35

Scheme 21: Hammett plot of $k_{\text {obs }}$ for hydroamination of 34 in the presence of Ar $_{3} P A u N T f_{2}$ reported by Toste et al. ${ }^{47}$
On the other hand protodeauration can be rate determining as well and then the use of an electron poor ligand would slow down the reaction rate. This is the case for the intramolecular hydroamination of propargylamide $36 .{ }^{46}$ Therefore the use of electron rich phosphines proved to be beneficial and full conversion could be obtained with tricyclohexylphosphine within one hour.

Scheme 22: ligand effect on the transformation of propargylamide 36 to oxazole 37. Reagents and conditions: 36 (0.5 M), gold precatalyst (5 mol\%), $\mathrm{CD}_{2} \mathrm{Cl}_{2}, r t$.

If catalyst deactivation occurs during the desired transformation, then this is also an important factor to consider during the catalyst design process. For example to avoid catalyst deactivation the biphenyl systems first reported by Buchwald proved to be useful, as due to the additional arene gold interaction and the steric bulk of the phosphine ligand, the aforementioned catalyst deactivation pathways (formation of digeminal gold complexes or formation of $\mathrm{Au}^{0}$ and bisligated $\mathrm{Au}^{+}$) are less likely to occur. As shown by Xu et al. ${ }^{46}$ the decomposition of gold complexes 37 to elemental gold (38) and dicoordinated gold species 39 occurs for ortho substituted phenyl triarylphosphine at a much slower rate than the one of even electronically different triarylphosphines.

Scheme 23: ligand effect toward to catalyst decomposition.
The possibility to tune the stereo electronic properties of the phosphines, enabled the broad applicability of these ligand class.

### 2.3 Applications of phosphines in $\pi$-acid catalysis

Jiang et al. ${ }^{48}$ reported in 2016 a $\pi$-acid catalysis, in which depending on the applied ligand ortho or para selective cyclization can exclusively be obtained. While XPhosAuNTf $\mathrm{X}_{2}$ (45$\mathrm{AuNTf}_{2}$ ) leads to dihydroquinoline 43 (para selective cyclisation, $87 \%$ ), the use of phosphite ligand 44 results in selective ortho cyclization to dihydroquinoline 42 (61\%). This ligand controlled reactivity could be broadened to 50 substrates.

[^13]

Scheme 24: ligand controlled ortho or para selective cyclization of phenyl propargyl amine 115 to dihydroquinoline 42 or $43 .{ }^{48}$

Another impressive example was published by Zhang et al. ${ }^{49}$ in 2014 controlling the antinucleophilic attack of alkynes through ligand design. Zhang et al. as well used the additional stability of ortho phenyl substituted phosphines and combined their beneficial effect with an additional directing group to enable the anti-nucleophilic attack of alkynes through precoordination of the nucleophile. Zhang et al. reported the addition of benzoic acid (46) to 1dodecyne (47) with low catalyst loadings ( 40 ppm ) yielding the desired 2 -dodecenylbenzoate (48) in excellent yield ( $97 \%$ ) after only 12 h of reaction time, once more demonstrating the power and utility of ligand design.

Scheme 25: ligand controlled anti addition of benzoic acid to dodecyne reported by Zhang et al. ${ }^{49}$

[^14]
## 3. Ligand design in Cross Coupling Reactions

### 3.1 Generalities, mechanism and scope

A cross coupling reaction is a reaction, in which two substrates are coupled in the presence of a metal centre. It is one of the most important reaction for the creation of new carbon-carbon bonds. Homo- (e. g. Glaser coupling) as well as heterocoupling reactions (e. g. Sonogashira reaction) are known and both types are applied in modern chemistry.

In general a cross coupling reaction starts with the generation of the active metal ${ }^{0}$ source. This metal undergoes an oxidative addition with a suitable organic halide generating a metal" centre. Subsequently the second reaction partner is transferred to the metal via transmetalation reaction. Reductive elimination then releases the product and regenerates the catalyst.

Scheme 26: schematic catalytic cycle of a cross coupling reaction.
Besides the ligand effect the oxidative addition is highly dependent on the nature of the used aryl halide. Amongst other ${ }^{50,51}$ Maseras et al..$^{52}$ showed experimentally and by calculations, that more labile aryl halides undergo oxidative addition at a higher rate, decreasing from Phl over PhBr and PhCl to PhF . Experimentally, this was proven using mass spectroscopy. The mass spectra clearly showed higher amounts of addition products for more labile aryl halides

[^15](Arl: 100\%, ArBr: >99\%, ArCl: 97\%, ArF ~10\%). This general trend was then confirmed by DFT calculations.

Figure 2: experimental and theoretical investigation of the oxidative addition performed by Maseras et al. ${ }^{52}$
The relative rate of different aryl residue should as well be considered and is roughly proportional to the relative rate in $S_{N} A r$ transformations of these substrates. ${ }^{53}$ This trend can be easily rationalized considering the reactivity of for example 2,5-dibromopyridine in Pd catalysed reactions. These take place regioselectively at the C 2 position, ${ }^{54}$ whereas palladiumcatalysed reactions of 2,4- or 2,6-dichloropyrimidines take place at C4 and C6 more readily than at C2. ${ }^{55}$

The rate of the transmetalation step is strongly influenced by the concentration of the base that is used..$^{56}$ While higher concentrations in $\left[\mathrm{OH}^{-}\right]$promote the transmetalation step due to the formation of formation of $\left[\mathrm{ArPd}(\mathrm{OH})\left(\mathrm{PPh}_{3}\right)_{2}\right]$, which reacts faster with $\mathrm{Ar} \mathrm{B}(\mathrm{OH})_{2}$ (for example in the Suzuki reaction). At the same time to high concentrations of $\mathrm{OH}^{-}$lower the reaction rate due to the deactivation of the transmetalation reagent (here the boronic acid is deactivated to the boronate). Further the rate of the transmetalation step is decreasing in the order of $\mathrm{Cl}>\mathrm{Br}$ $>$ I, which is the reverse order of the oxidative addition. ${ }^{57}$ The electronics of the transmetalation reagent matter as well. More electron rich fragments are often faster transmetalated, while at

[^16]the same time the steric bulk of the coupling partners slows down the rate of the transmetalation step. ${ }^{58}$

The reductive elimination step is as well promoted by the presence of base through the generation of a pentacoordinated anionic palladium complex. ${ }^{56}$ This can be attributed to a general steric effect, which as well promotes the reductive elimination, if enough steric bulk is present on the two coupling partners and the ligands. The electronic structure of the coupling partners significantly increases the rate of the reductive elimination as shown by Hartwig et al. ${ }^{59}$ on the basis of platinum complexes. While this elementary step is considered facile for coupling partners with different electronic structures (e.g. one electron rich and electron poor one), the reductive elimination is more difficult for electronically similar coupling partner (e.g. two electron rich or two electron poor ones).

Figure 3: Qualitative energy diagram for the comparison of the rates of reductive elimination from (DPPF)Pt( $\left.\mathrm{C}_{6} \mathrm{H}_{4}-4-\mathrm{CF}_{3}\right)_{2}$ and (DPPF)Pt( $\left(\mathrm{C}_{6} \mathrm{H}_{4}-4-\mathrm{CF}_{3}\right)-\left(\mathrm{C}_{6} \mathrm{H}_{4}-4-\mathrm{NMe}_{2}\right)$ reported by Hartwig. ${ }^{59}$

In some cases the rates of all elementary steps in the catalytic cycle can be improved through ligand design. For example with bulky, electron rich ligands the oxidative addition is promoted electronically, while the reductive elimination is facilitated by the steric repulsion of the metals ligand and the substrate residues. ${ }^{60}$

A Nobel Prize was even attributed to Heck, Negishi and Suzuki for their development of palladium catalysed cross coupling reactions in 2010. ${ }^{61}$ While classically aryl halides and boronic acids had been used for the cross coupling reaction (for example Suzuki reactions) ${ }^{62}$,

[^17]the general reactivity could amongst other be expanded to organohalides with organozinc compounds (Negishi coupling) ${ }^{63}$, organotin compounds (Stille coupling) or organosilicon (Hiyama coupling) compounds, to alkenes with aryl halides (Heck coupling) or even to aryl halides with amines (Buchwald-Hartwig amination). Therefore nowadays cross coupling reactions allow access to a broad range of different products. Not surprisingly the ligand design plays as well a prominent role to tune the metal properties and reactivity to exclusively yield the desired compounds.

### 3.2 Influence of the ancillary ligand in cross coupling reactions

The ligand plays an important role in all elementary steps necessary for a given transformation and its influence to each step will be discussed later on. Besides the electronic influence the ligand also acts via its steric effects, which in general stabilize the metal centre, shielding it from other molecules (e.g. water) to avoid side reactions. This additional stabilisation achieved through ligand design can easily be realized, comparing the reactivity of palladium acetate, tetra triphenylphosphine palladium and SPhos palladium salts. While in palladium acetate the ligand shields the metal only minorly from undesired reactivity, in the triphenylphosphine palladium complex a better shielding can be obtained through the steric bulk of the ligand. The shielding can even be further improved as realized by Buchwald type ligand, which shield the metal centre through their steric bulk and a secondary arene metal interaction avoiding almost all side reaction. This results in a net improvement of the catalytic activity of the metal systems employed and impressive high turnover numbers can be obtained for those systems. However, if the steric bulk is increased even further at a certain point the substrate is not able to add to the metal centre and thereby the reactivity is completely blocked. Therefore, the steric bulk of the employed ligand system needs to be optimised with care.

Scheme 27: steric protection of palladium ${ }^{0}$.
Besides the steric bulk the electronic properties of the used ligands play a tremendous role as well, because for each elementary step the ligand can either be beneficial or detrimental. For example while the oxidative addition is promoted by electron rich ligands for example carbenes, those will be unfavourable for the reductive elimination, where electron poor ligands

[^18]are beneficial. For the transmetalation step studies from Farina ${ }^{64}$, Espinet ${ }^{65}$, Amatore and Jutand ${ }^{66}$ suggest, that for phosphine ligands an indirect electronic effect is observed due to the loss of one ligand before or during the transmetalation step and therefore it is more a steric, than an electronic effect. This trend was further underlined by Clarke et al. ${ }^{67}$ They tested the influence of bidentate ligands in the transmetalation of phenyl zinc bromide to platinum complexes. While changing the electronic nature of the ligands from more electron rich phosphine (depe) to more electron poor ligands (dppe) no significant influence (both 100\% yield after 18 mins ) was observed, increasing the steric bulk significantly inhibits the reactivity (dcype: 62\% yield and dtbpx: 0\% yield after 18 mins).

dtbpx, 0\%

dfppe, 100\%

Scheme 28: influence of the ligand to the transmetalation step in cross coupling reactions.
A steric influence to the reductive elimination was as well reported by Buchwald et al. ${ }^{68}$ They realized that by the extended steric bulk of the ligand the rate of the reductive elimination is increased as both residue at the metal centre are pushed away. Overall, to successfully tune the rate of a given transformation all elementary steps need to be considered. If this concept is applied successfully high reactivities and selectivities are achieved in cross coupling reactions. Therefore, we can find a broad range of highly developed ligands for different types of cross coupling reactions, once more demonstrating the power of ligand design.

### 3.3 Application of phosphines in cross coupling reactions.

Phosphines in general and for instance triphenylphosphine are applied in a broad range of coupling reaction amongst others in the Heck-, Stille-, Suzuki-Miyaura-, and Kumada coupling. Additional noteworthy ligands based on the dialkylbiaryl phosphines used in palladium

[^19]chemistry were reported by Buchwald et al. ${ }^{68}$ and applied in C-N bond formations. Buchwald et al. ${ }^{68}$ reported the preparation of SPhos (50), XPhos (51), BrettPhos (52) and DavePhos (53) as well as their application in palladium catalysed $\mathrm{C}-\mathrm{C}$ and $\mathrm{C}-\mathrm{N}$ bond formations.

Suzuki-Miyaura and Sonogashira coupling reactions in water were reported with the anionic Buchwald type ligands in excellent yields for a broad range of substrates (over 25 examples) and even at room temperature an impressive Suzuki-Miyaura coupling could be performed in water with low catalyst loading ( $2 \mathrm{~mol} \%$ ) converting chloroarene 57 to biphenyl 59 in excellent yield (97\%) within 2 hours.

Scheme 31: Suzuki-Miyaura coupling in water with anionic ligand.

## 4. A new strategy to modify the donor properties of phosphines

Our group reported a new strategy to modify phosphine ligands. Although charged phosphines are already reported in literature, these usually bear the cationic charge at a remote position having low influence on the donor and acceptor properties of the corresponding phosphines. Direct attachment of the positive charge $\alpha$ to the phosphine was first reported by Kuhn et al. ${ }^{70}$, but the systematic applications of their donor properties were largely overlooked. The strong inductive effect of the introduced positive charge, significantly reduced the $\sigma$-donor abilities of $\alpha$-cationic phosphines. At the same time, the energy of the $\sigma^{*}\left(\mathrm{P}-\mathrm{C}^{+}\right)$orbitals is further decreased, increasing their $\pi$-acceptor character, and as consequence, the global electron donation of these ligands to the metal is quite low. Only polyhalogenated phosphines such as $\mathrm{PF}_{3}, \mathrm{P}_{\left(\mathrm{CF}_{3}\right)_{3} \text {, or } \mathrm{PCl}_{3} \text { depict similar electronic properties, but are, because of the labile }}$ phosphorus-halogen bond, much more sensitive to moisture and water and therefore, more difficult to handle. Hence, $\alpha$-cationic phosphines are in this regard superior to the hereto known electron poor, but sensitive ligands. The effect, caused by the introduction of different $\alpha$ cationic residues, to the frontier orbital on phosphines was reported by our group (Figure 5: frontier orbital for cationic phosphines.) The introduction of a cationic charge significantly lower the energy of the corresponding HOMOs in comparison to triphenylphosphines. However, for the different cationic phosphines the energy of the corresponding HOMOs is relatively close to each other ( -9.05 eV to -9.85 eV ), indicating, that the $\sigma$-donation of the different cationic phosphine is similar. Conversely the LUMOs are diminished in a much wider range ( -4.1 eV to -6.34 eV ), confirming, that the neat reduction of global electron density is a result of the enhanced $\pi$-acceptor properties.

Figure 5: frontier orbital for cationic phosphines.

## $4.1 \alpha$-monocationic phosphines

As mentioned before our group and others developed $\alpha$-cationic phosphines.

61, Kuhn

62, Bertrand

63

64

65
Alcarazo

Scheme 32: developed $\alpha$-cationic phosphines.

The first $\alpha$-cationic phosphine 61, which was based on an imidazolium moiety, was reported by Kornilov ${ }^{69}$ and further developed by Kuhn, ${ }^{70}$ Wasserscheid ${ }^{71}$ and Tkatchenko. ${ }^{72}$ Through generation of the carbene by decarboxylation of imidazolium zwitterion 66 and attack towards different disubstituted phosphine chlorides the corresponding imidazolium phosphines 61a-c were obtained in moderate to good yields (58-90\%). This synthetic strategy however could not be extended towards the preparation of other cationic phosphines as the generation of the corresponding carbene is difficult or the attack towards the phosphine does not occur in the desired selectivity.

Scheme 33: generation of imidazolium phosphines 51a-c.
For this reason our group ${ }^{73}$ developed a more general synthetic strategy consisting of direct condensation of a secondary phosphine with a Vilsmeier-type salt and could extend the scope of cationic phosphines to cyclopropenium ${ }^{-74}$, imidazolinium- ${ }^{75}$ and formamidinium phosphines. Cyclopropenium phosphines 63a-f with different substitution patterns at the phosphorus atom were obtained in good to excellent yields (76-96\%) through direct condensation of chlorocyclopropenium salt $\mathbf{6 7}$ followed by anion exchange. This reaction allows the preparation of cyclopropenium phosphines on a multiple gram scale as white and air stable solids.

[^20]

Scheme 34: generation of cyclopropenium phosphines
Introducing the electron poor polyfluorinated phosphine 68 via the aforementioned condensation failed, due to the low nucleophilicity of the phosphine. Therefore, deprotonation is necessary to achieve the condensation reaction to the corresponding cyclopropenium salt $63 \mathrm{~g}^{76}$.

Scheme 35: condensation of phosphine 68 with cyclopropenium salt 67.
In addition to the modification of the phosphine moiety, an alteration of the cyclopropenium substituent is possible and formamidinium and imidazolinium residues can be introduced, yielding the corresponding cationic phosphines 64a-b and 65.

[^21]

Scheme 36: preparation of imidazolinium- and formamidinium phosphines.
A report by Roesky et al. ${ }^{77}$ mentions CAAC based cationic phosphine 73 obtained as byproduct instead of the desired formation of silaphosphine 74, however, applications of phosphine 73 are until now not reported.

Scheme 37: formation of CAAC phosphine 73.

## $4.2 \alpha$-polycationic phosphines

To increase the influence of the positive charge, not only monocationic, but di- and even tricationic phosphines have been prepared.

Cattey et al. ${ }^{78}$ reported the preparation of dicationic imidazolium substituted phosphine 75, which was prepared through addition of the corresponding carbene towards phenylphosphinedichloride. Unfortunately, purification of this compound proved to be difficult

[^22]and the product was still contaminated with $10 \%$ of starting material even after extensive washing.

Scheme 38: preparation of dicationic phosphine 75.
Alcarazo et al. ${ }^{79}$ reported the preparation of dicationic cyclopropenium phosphine 76a and its derivatives ${ }^{80}$ and could prepare several new dicationic cyclopropenium phosphines 76b-f in moderate to good yields. Their synthesis strategy either consisted of halogen/lithium exchange followed by addition towards the dichlorophosphine similar to Cattey et al. ${ }^{78}$ or through a stepwise condensation of primary phosphines with chlorocyclopropenium salts.

76b: 63\%

76c: $41 \%$
76d: 73\%

76c: $50 \%$
76d: 32\%
76e: 23\%
76f: 49\%

Scheme 39: preparation of dicationic phosphine 62a-f
In addition to the modification of the phosphine substituents this reliable synthesis plan tolerates modification of the amine substituents as well as allowing fine tuning of the solubility properties of the resulting phosphines. For example the preparation of butyl and hexyl substituted dicationic phosphines 76 g and 76 h is reported ${ }^{80}$ as well, employing the same preparation method.

[^23]

Scheme 40: preparation of dicationic phosphines $76 \boldsymbol{g}$ and $\boldsymbol{h}$.
Furthermore the synthetic strategy could be extended to bis-imidazolinium- and bisformamidinium phosphines 78 and 79a-b in moderate to good yields (24-73\%).

Scheme 41: synthesis of bis-imidazolinium and bis-formamidinium substituted phosphines 78 and $\mathbf{7 9 a - b}$.
The most extreme $\pi$-acceptor phosphines prepared so far were reported by Bertrand et al. ${ }^{81}$ (based on DBU - 82) and Alcarazo et al. ${ }^{82}$ (based on cyclopropenium -84), and are tricationic ones. The syntheses are based on the "onium" and reversed "onium" strategy ${ }^{83}$, a direct condensation of a cationic residue with the release of trimethylsilylchloride. Both structures could be verified by solid state analysis, however only Alcarazo reported further applications of the tricationic system.

### 4.3 Evaluation of the stereo electronic properties

To understand why the additional positive charge is beneficial in terms of reactivity and reaction rate, one needs to understand the nature of the interactions between the phosphine and the metal as well as the influence of the cationic charge towards the interactions. A model is introduced to explain the interactions between phosphine and metal. Furthermore, the phosphine's electronic and steric parameter are categorised using different models. This discussion then led to the interactions between metal and substrate depending on the employed phosphines, which explains the observed reaction rates and selectivities.

The ligands interact with the metal by $\sigma$-donation from the phosphorus lone pair to an empty $d$-orbital of the metal, while at the same time a metal's full d-orbital interacts by $\pi$-backdonation to the three $\sigma^{*}$-orbital of the phosphorus and the phosphorus substituents bonds.

Figure 6: interactions between metals and phosphine ligands, $\sigma$-donation and $\pi$-backdonation.
Depending on the electronic properties of the phosphine, the amount of $\sigma$-donation and $\pi$ backdonation differs. It has been shown by calculations, that the main interaction is usually the $\sigma$-donation. ${ }^{84}$ Only for the most electron poor phosphines for example tricationic phosphines or $\mathrm{PF}_{3}$ the $\pi$-backdonation is the main interaction between the phosphine and the metal, because of the more efficient orbital overlap between the $\sigma^{*}$ orbital (which lies lower in energy) and the metal d-orbitals. ${ }^{97}$

On the other hand, electron rich phosphines show stronger $\sigma$-donation, for example in $\mathrm{PtBu}{ }_{3}$ the phosphorus-metal interaction is strengthened by the inductive effect of the tert-butyl groups.

To classify the electronic structure of different phosphines, Tolman et al. ${ }^{85}$ introduced an electronic parameter in 1970 measuring the CO stretching frequencies of the corresponding nickel carbonyl complexes, which was later named Tolman electronic parameter (TEP). Despite the high toxicity of nickel tetra-carbonyl, these complexes were chosen as model for the TEP being easily prepared by mixing the ligand and $\mathrm{Ni}(\mathrm{CO})_{4}$ in a 1 to 1 ratio. Furthermore the $\mathrm{A}_{1}$ band of the carbonyl group is sharp and therefore can be measured with high accuracy. Depending on the aforementioned effect of $\sigma$-donation and $\pi$-backdonation of the employed phosphine the electron density of the metal changes, resulting in different interactions of the metal with the carbonyl group causing the C-O stretching frequencies to shift. The interaction between the metal and the carbonyl group consist of $\sigma$-donation and $\pi$-backbonding. As both fragments - the phosphine moiety as well as the carbonyl ligand - compete for the electron density of the metal, the electronic characterisation of the carbonyl unit through infrared analysis corresponds to the electronic nature of the phosphines as well. Therefore, the CO stretching frequency is relevant for the quantification of the ligands donor and acceptor properties. More $\pi$-backdonation from the metal towards the carbonyl group leads to a higher

[^25]population of the antibonding $\pi^{*}$ orbital of the carbonyl group and hence, the carbonyl bond order decreases, leading to higher CO stretching frequencies. This results in lower CO stretching frequencies for better $\sigma$-donor ligands, while higher CO stretching frequencies are observed for better $\pi$-acceptor ligands. Consistent with this trend a few examples of phosphine ligands reported by Tolman ${ }^{86}$ and their TEPs are shown in table 1.

Figure 7: interactions between nickel and carbonyl ligands, $o$-donation and $\pi$-backdonation.

Table 2: Tolman electronic parameter of a range of ligands. ${ }^{86}$
In addition to the TEPs of phosphines their steric environment needs to be considered as well. Thus, Tolman defined the steric parameter $\theta$, nowadays known as the Tolman angle. ${ }^{86}$ The Tolman angle is defined as the weighted apex angle to the outermost atom of each substituent of the phosphorus of a cone, centred $2.28 \AA$ from the centre of the phosphorus atom (see Equation 1 and Figure 8). Consistent with the expectations, a few examples of the Tolman angle for more established ligands are shown.

$$
\begin{equation*}
\theta=2 / 3 \sum_{i=1}^{3} \theta_{i} / 2 \tag{Eq.:1}
\end{equation*}
$$

[^26]

Figure 8: Tolman cone angle determination of unsymmetrical phosphines.

| Ligand | $\theta\left[{ }^{\circ}\right]$ | Ligand | $\theta\left[{ }^{\circ}\right]$ |
| :---: | :---: | :---: | :---: |
| $\mathrm{PH}_{3}$ | 83 | $\mathrm{PPh}_{3}$ | 145 |

| $\mathrm{P}\left(\mathrm{CF}_{3}\right)_{3}$ | 137 | $\mathrm{PMes}_{3}$ | 212 |

Combining the electronic and steric effect of all examined ligands then led to a stereo electronic map ${ }^{86}$ - nowadays known as Tolman stereo-electronic map. This map allows to design new ligands, with the necessary electronic or steric properties, or to choose among the already established ligands for a particular transformation for example to enhance reactivity or to improve selectivity.

Figure 9: Tolman stereo electronic map.
Due to the high toxicity of nickel tetra-carbonyl numerous alternatives besides the Tolman stereo electronic map have been developed to characterise the donor and acceptor properties of phosphine ligands. Analogously to the nickel carbonyl stretching frequencies rhodium or tungsten carbonyl stretching frequencies can be measured to characterise the ligands. The rhodium or tungsten carbonyl complexes are as easily prepared and do not stem the high toxicity of nickeltetracarbonyl. Unfortunately, the analysis of their corresponding CO stretching frequencies shows a strong dependency upon the applied method (e. g. dissolved or solid) ${ }^{87}$ and the used solvent. In case of the rhodium carbonyl frequencies measurements even nonlinear effects ${ }^{88}$ were observed. Therefore, the CO stretching frequencies of the corresponding complexes can be compared, but with care.

86

87

Scheme 44: carbonyl complexes of rhodium and tungsten used for the determination of the ligands donor and acceptor properties.

[^27]Another method to measure the donor/acceptor properties of ligands is the cyclic voltammetry ${ }^{89}$. In cyclic voltammetry the reduction and oxidation potential of the molecule under study, is measured and referenced against a standard potential (for example ferrocene). Comparing these potentials then allows to rank the donor and acceptor properties of the examined ligands. The advantage of this method is the independence of the steric bulk of the examined system, while the disadvantage is that additional functional group could easily get reduced or oxidized. These are not relevant for the coordination process, but still result in signals in the cyclic voltammogram, which might lead to misassignments. Furthermore, through cyclic voltammetry the reversibility of the reduction and oxidation processes is measured as well, yielding additional information about the radicals generated during the measurement. In Figure 10 a typical cyclic voltammogram is shown.

Figure 10: typical cyclic voltammogram of a reversible reduction.
In the literature apart from the Tolman angle the buried ligand volume $\% \mathrm{~V}_{\text {bur }}$ was introduced by Nolan et al. ${ }^{90}$ to access the steric parameter, which allows the characterisation of the steric bulk of all types of ligands including phosphine ligands. The buried ligand volume is defined as the volume of a sphere occupied by the ligand. The sphere has a radius of $3 \AA$ and is centred $2 \AA$ next to the ligand with a metal at its centre. $\% \mathrm{~V}_{\text {bur }}$ shows an excellent correlation with the Tolman angle for a broad range of phosphines ( $\mathrm{R}=0.981)^{91}$ and can further be extended to chelating phosphines or even carbene systems, which could not be characterised well with the Tolman angle. However it should be noted, that the Tolman angle and \% $\mathrm{V}_{\text {Bur }}$ are not correlating the phosphites as good as the phosphines.

[^28]

### 4.4 Applications of cationic phosphines

The new cationic phosphines showed great potential and therefore, the metal complexes of the cationic phosphines were applied in a vast amount of $\pi$-acid catalysis systems. The phosphines themselves after quaternisation as reported by Stephan et al. ${ }^{92}$ show reactivity in hydrodefluorinations of fluoroalkanes and in hydrosilylation of alkenes and alkynes. Further applications of cationic phosphines include Negishi coupling (Knochel et al. ${ }^{93}$ ), Sonogashira coupling, hydrogenations (both by Picquet et al. ${ }^{94}$ ) and hydroformylations (Wasserscheid et al. ${ }^{95}$ ).

97

99, >99\%

92

Scheme 45: applications of cationic phosphines.
Alcarazo et al. ${ }^{79}$ showed, that the application of cationic phosphines in $\pi$-acid catalysis after coordination to gold or platinum sources enhances the reaction rate of some transformations tremendously. A strong beneficial ligand effect was present in the hydroarylation of strained biphenylsystem 100 towards phenanthrene moiety 101. A broad range of different phenanthrenes (over 15 examples) could be prepared by this newly developed method, including some natural products (Coeloginin (102), Epimedoicarisoside A (103) and Calanquinone $C(104)) .{ }^{76}$

[^29]

Scheme 46: ligand effect in the cyclization of biphenyl 100 to phenanthrene 101. ${ }^{76}$

102, Coeloginin

103, Epimedoicarisoside A

104, Calanquinone C

Scheme 47: natural products synthesised employing cationic phosphines.
The aforementioned cationic phosphines proved to catalyse a broad range of different gold $(\mathrm{I})$ and platinum(II) catalysed reactions, for example the enine cyclisation of amine $\mathbf{1 0 5}$ to tricyclic
system $106^{96}$, the hydroarylation of $\mathbf{1 0 8}^{\mathbf{7 9}}$, the cyclopropanation of styrene (112) ${ }^{\mathbf{7 4}}$ and the hydroxyl abstraction of $\mathbf{1 1 5}^{\mathbf{7 4}}$.

105

106

107

109

114

Scheme 48: applications of cationic phosphines/arsines in gold and platinum catalysis.

Despite their high reactivity towards moisture the tricationic phosphines showed great rate enhancement in platinum catalysis ${ }^{97}$. An example is the cyclisation of 2-ethynyl-1,1'binaphthalene (118) into [5-carbo]helicene (119). While classical ligands still catalyse the cyclisation reaction, better $\pi$-acceptor ligands lead to a rate acceleration. While triphenylphosphine only converts $25 \%$ of the starting material, $\mathrm{P}\left(\mathrm{C}_{6} \mathrm{~F}_{5}\right)_{3}(\mathbf{1 2 0})$ already converts $50 \%$ of the starting material. The use of tricationic ligand platinum complexes 121 and 122 further enhances this beneficial effect and resulted in full conversion within 90 min . and proves

[^30]the positive influence of cationic charges in $\pi$-acid catalysis. The tricationic phosphine 84 was also applied in the synthesis of 21 additional phenanthrene derivatives.

Figure 12: ligand effect on the hydroarylation of biphenyl derivative 118 to pentahelicene 119. Reagents and conditions: biphenyl 118 ( 0.05 M ), platinum precatalyst ( $5 \mathrm{~mol} \%$ ), $\mathrm{AgSbF}_{6}(5 \mathrm{~mol} \%),\left(\mathrm{CH}_{2} \mathrm{Cl}\right)_{2}, 80^{\circ} \mathrm{C}$.

Alcarazo et al..$^{98}$ reported the cyclization of diynes (e.g. 123) to [6]carbohelixenes (e.g. 124). While classically used phosphoramidites could not perform this transformation at $-20^{\circ} \mathrm{C}$ (no conversion), the newly developed cationic phosphonites (e.g. 125) allowed to achieve for multiple enyne substrates excellent yields (up to $98 \%$ ), selectivities (up to 99:1) and

[^31]enantioselectivities (up to $99 \%$ ee) for this hydroarylation reaction. Once more demonstrating the beneficial influence of an additional positive charge to established ligand frameworks.

Scheme 49: enantioselective cyclization promoted by $\alpha$-cationic gold phosphine complex.

## 5. Motivation

The previously described cationic phosphines, despite their impressive reactivity, carry several disadvantages as well. First, to achieve better reactivities than commercial phosphite or polyfluorinated phosphines the introduction of two cationic charges is necessary. This renders the phosphines very insoluble. Therefore, the corresponding complexes can be rarely used in common, less polar solvents. Due to the number of charges the phosphines and the corresponding complexes are not as stable as monocationic phosphines and undergo side reactions with nucleophiles, limiting the scope of reactions employing dicationic systems. Moreover, the high number of steps for the preparation of dicationic systems further renders modifications of the dicationic systems rather difficult and time consuming. While the alternative introduction of polyfluorinated phosphines avoids the disadvantages of dicationic systems at the same time and similar reactivities to dicationic systems can be achieved, the polyfluorinated systems themselves carry several disadvantageous as well. For example the difficult introduction and high price of these phosphines, limiting once again the scope and flexibility of the prepared cationic phosphines. Furthermore, polyfluorinated phosphines are not environmental benign and therefore should as well be avoided if possible. Therefore, the development of new, highly reactive phosphines is necessary.

## 6. Objective

This dissertation focuses on the development of new $\pi$-acceptor ligands, based on the pyridinium moiety, and their applications in gold, platinum and palladium chemistry.

The pyridinium system are not only easily accessible, but are as well easy to modify, allowing a broad range of modifications and fine tuning for a specific reaction or reaction class. For example the pyridinium phosphines can be modified at the nitrogen, the five position of the pyridinium ring and the phosphine moiety rather easily, while up to now reported systems are not as easily modifiable and would rely on a multistep synthesis for modifications as mentioned before. Although pyridinium phosphines only incorporate one charge, they are expected to be highly reactive in $\pi$-acid catalysis, as was shown by calculation of the lowest unoccupied molecular orbital discussed before. Therefore, even though the pyridinium phosphines will show as high reactivities as dicationic systems, they will not incorporate their disadvantages of lowered solubility. In addition, their easy modulation should further allow the fine tuning and improvement of the pyridinium phosphine complexes to outperform even dicationic systems in catalysis.

After the development of those phosphines we then aim to characterize their donor/acceptor properties through classical CO-stretching frequency analysis, solid state analysis and cyclic voltammetry.

Furthermore, we want to apply the newly developed pyridinium phosphines in gold, platinum and palladium catalysis and show their beneficial effect towards the reaction rate of a given transformation.

## 7. Results and Discussion

### 7.1 Synthesis of pyridinium phosphines

The cationic pyridine residue renders the phosphine a better $\pi$-acceptor even in comparison to the dicationic cyclopropenium substituted phosphines. Therefore, allowing the access to a more reactive catalyst without the disadvantages of dicationic systems (low solubility and a less stable phosphine metal bond).

The synthesis of pyridinium substituted phosphines was achieved in good to excellent yields in only two steps - direct methylation of 2-chloropyridine with Meerwein salt followed by phosphination with the corresponding phosphine.

Starting from the readily available chloropyridines 126a-d electron rich and electron poor pyridinium salts 127a-d (methoxy, fluoro and trifluoromethyl substituted) were obtained by N alkylation with trimethyl oxonium tetrafluoroborates in excellent yields (89-99\%).

Scheme 50: methylation of chloropyridins.
Besides N -methylation the strategy could be extended towards ethylation of 2-chloro-5(trifluoromethyl) pyridine, 2-chloro-5-nitro pyridine and 2-chlor pyridine in excellent yields (98$99 \%)$. The ethyl group increases the solubility of the obtained products 129a-c and that of the final phosphines.

Scheme 51: ethylation of 2-chloro-5-(trifluoromethyl) pyridine.
Even better solubility was obtained introducing butyl- and octyl chains. This was achieved through a copper catalysed coupling ${ }^{99}$ of pyridone with butyl- or octylbromide (both 63\%) followed by chlorination (78-81\%).

[^32]

Scheme 52: synthesis of butyl and octyl substituted pyridinium salts.
With all the chloropyridinium precursors in hand, the direct nucleophilic aromatic substitution was performed with different secondary phosphines yielding a broad range of cationic phosphines in moderate to excellent yields (30-89\%). Despite the different electronic structures of the chloropyridinium salts, good yields were obtained for electron poor and electron rich precursors upon direct phosphination (124a-h,k,l; 43-89\%), only in case of the nitro substituted pyridinium salt $\mathbf{1 2 4 k}$, no product could be isolated and a complex mixture was obtained. This undesired reactivity is most likely caused by the additional redox-active nitro group reacting with the employed phosphines. The synthesis of the cationic phosphine 124i showed to be more difficult - although the crude NMR showed high conversion (90\%) - removal of potassium salts as well as anion exchange proved to be difficult, leading to a rather low yield (30\%).

Scheme 53: synthesis of pyridinium phosphines.
The newly developed phosphines are in case of the diphenylphosphine derivatives crystalline, white and air stable solids, which were easy to handle. The new phosphines are in comparison to dicationic systems more soluble in common solvents and even stable towards water.

To confirm the structure, a few of the phosphines prepared were crystallized and examined by X-ray crystallography, confirming the desired connectivity. The bond lengths (1.852-1.865 Å) between the phosphorus atom and the carbon C 1 of the pyridinium moiety suggest, that significant charge density resides on the phosphorus atom and nicely illustrates, that the phosphorus lone pair still is available for coordination. This is further underlined through the significant pyramidal environment around the central phosphine atom (303.79$\left.{ }^{\circ}-304.87^{\circ}\right)$.

Table 4: chosen bond distances and pyramidal environment around the phosphorus atom of crystallised cationic phosphines.

Next we evaluated the stereo electronic properties of the prepared phosphines. As before mentioned this can be done comparing the Tolman angle and the Tolman stereo-electronic parameter of the corresponding phosphines. Despite the high toxicity of nickeltetracarbonyl we attempted the synthesis of the corresponding nickel carbonyl complexes. However these could not be prepared, as they probably decomposed upon removal of the solvent.

As the preparation of the nickel carbonyl complexes failed, we instead prepared the rhodium(I) Vaska type complexes 135a-f in good to excellent yields (57-99\%). A simple quadratic function (Eq. 1.0) then allows as described by Roodt et al. ${ }^{100}$ to correlate the carbonyl stretching frequencies to Tolman electronic parameter.

$$
y=a x^{2}+b x+c \text { (Eq.: 1.0) }
$$

Equation 1: correlation between $v(C O N i)$ and $v(C O R h)$ with $a=(2.77 \pm 0.44) \times 10^{4}, b=(-2.65 \pm 0.45) \times 10$ and $c=(6.8 \pm 1.1) \times 10^{-3}$

[^33]
## Hendrik Tinnermann

135g, 78\%
$v(C O)=1982 \mathrm{~cm}^{-1}$

135i, 60\%
$v(C O)=2001 \mathrm{~cm}^{-1}$ frequencies.

For the prepared complexes the CO stretching frequencies directly correlates with the $\pi$-acidity of the corresponding phosphines. As more $\pi$-acidic phosphines deplete more electron density from the metal, less backdonation from the metal to the carbonyl groups antibonding $\pi$-orbital can occur and therefore the CO bond is stronger, resulting in higher CO stretching values for more $\pi$-acidic phosphines.

The CO stretching frequencies of the new pyridinium phosphines (1994 to $2004 \mathrm{~cm}^{-1}$ ) clearly show their enhanced $\pi$-acidity in comparison to the previously reported cyclopropenium phosphines (1968 to $1976 \mathrm{~cm}^{-1}$ ). Furthermore, the pyridinium phosphines even reach CO
 However, within the pyridinium phosphines this general trend is not followed and for example the more electron deficient polyfluorinated pyridinium phosphine 135i shows a lower CO stretching $\left(v(C O)=2001 \mathrm{~cm}^{-1}\right)$ frequency than the trifluoromethyl substituted pyridinium phosphine 135b $\left(v(C O)=2003 \mathrm{~cm}^{-1}\right)$.

Scheme 56: comparison of the carbonyl stretching frequencies of commercial, known and newly prepared phosphine Vaska type complexes.

As suspected, that spatial restrictions cause the inconsistency between the CO stretching frequencies and the electronic structures of the pyridinium phosphines, we crystallized rhodium complex 135c.

Figure 13: molecular structure of $\mathbf{1 3 5 c}$ in the solid state. Hydrogen atoms and anions are omitted for clarity. Anisotropic displacement parameter are shown at 50\% probability level.

The analysis of the crystal structure directly reveals a distortion from the ideal square planar geometry at the rhodium atom ( $\angle \mathrm{ClRh}(\mathrm{CO})=163.3^{\circ}$ and $\angle \mathrm{P} 1 \mathrm{RhP} 2=172.8^{\circ}$ ), that strongly influences the back bonding of the phosphine ligand towards the metal and, in return, from the metal towards the carbonyl group, as the orbital overlap due to this distortion is less efficient. This is the origin of the misleading CO stretching values as observed ${ }^{101}$.

We therefore did not calculate the TEP based on the carbonyl values of the Vaska type complexes as described before, but instead calculated the carbonyl stretching frequencies of $\mathrm{L}-\mathrm{Ni}(\mathrm{CO})_{3}$ complexes by DFT (blue dots) and measured the carbonyl stretching frequencies of the stable cationic phosphine nickel carbonyl complexes (red dots). ${ }^{102}$ Combined with the measured cone angle of the phosphine metal complexes, we were able to add the newly prepared cationic phosphines to the Tolman stereo electronic map.

[^34]

Figure 14: Tolman stereo electronic map with additional $\alpha$-cationic phosphines.
The nickel carbonyl stretching frequencies both calculated and experimental ones are in good agreement with the expectation. This confirms a higher $\pi$-backdonation towards the newly prepared pyridinium phosphines in comparison to the previously published monocationic cyclopropenium phosphines. The pyridinium phosphines reach $\pi$-acceptor properties of dicationic cyclopropenium phosphines and are better $\pi$-acceptors than polyfluorinated phosphines or even phosphites.

Besides theoretical calculations we also used cyclic voltammetry to measure the electrochemical properties of the prepared pyridinium phosphines to get experimental proofs for the predicted high $\pi$-acidity.

In cyclic voltammetry the potential to remove one electron from the examined compound is measured (the so called oxidation potential). The oxidation potential directly correlates with the phosphines $\sigma$-donor properties. The more difficult it is to remove the electron from the phosphine (higher oxidation potential), the worst $\sigma$-donor this ligand is. Besides the oxidation potential, the reduction potential (adding one electron to the examined compound) is measured as well and this can be correlated with the $\pi$-acceptor properties. Furthermore the reversibility of the oxidation and reduction process at different scan rates can be examined, indicating the life times of the corresponding radicals.

Scheme 57: oxidation potentials of commercial, cyclopropenium and pyridinium substituted phosphines, [a] Values in $\mathrm{cm}^{-1}$. [b] Oxidation peak potentials reported in V. Calibrated versus ferrocene/ferrocenium ( $E_{1 / 2}=0.24 \mathrm{~V}$ ), Bu ${ }_{4} N P F_{6}(0.1 \mathrm{M})$ in $\mathrm{CH}_{2} \mathrm{Cl}_{2}$, [c] measured in $\mathrm{CH}_{3} \mathrm{CN}$.

By comparison of the obtained oxidations potentials the expected trend of reduced $\sigma$-donation from phosphine ( $E_{o x=} 0.697 \mathrm{~V}$ ) to phosphite ( $\mathrm{E} o x=1.287 \mathrm{~V}$ ) and cyclopropenium phosphine ( $E_{o x=1.207 ~ V) ~ t o ~ p y r i d i n i u m ~ p h o s p h i n e ~(~}^{\text {Kox }}=1.398-1.578 \mathrm{~V}$ ) could be validated. Furthermore, the effect of different substitution patterns ( $-\mathrm{OMe},-\mathrm{F}_{\mathrm{C}}-\mathrm{CF}_{3}$ ) and their electronic effects in cyclic voltammetry line up well, confirming, for example that the $\mathrm{CF}_{3}$ substituted phosphine 124c ( $E_{o x}=1.578 \mathrm{~V}$ ) is even more electron poor than the dicationic cyclopropenium phosphines ( $\mathrm{E}_{0 \mathrm{x}}=1.541 \mathrm{~V}$ ). Therefore, during the catalytic experiments the newly developed system should show a superior reaction rate compared to classical phosphine ligands, like triphenylphosphine and triphenylphosphite, or even dicationic cyclopropenium phosphines.

### 7.2 Synthesis of metal complex derivatives

### 7.2.1 Platinum complexes

The new zwitterionic platinum complexes were prepared by addition of the corresponding phosphine to $\mathrm{K}_{2} \mathrm{PtCl}_{4}$ in acetonitrile. The desired platinum complexes $\mathbf{1 3 6} \mathbf{a}, \mathbf{b}$ were obtained as white air stable solids in moderate to good yields (40 and 80\%).

Scheme 58: synthesis of platinum complexes.
Comparison of their structure to the one of the $\mathrm{PtCl}_{4}{ }^{2-}$ unit in $\mathrm{K}_{2} \mathrm{PtCl}_{4}$ allowed us to evaluate the strength of the trans-effect of our ligands compared to chloride. Although we would expect - as cationic phosphines are weak $\sigma$-donors - a weaker trans influence compared to chloride, we did observe the opposite as revealed by the elongated $\mathrm{Pt} 1-\mathrm{Cl} 2$ bond $(2.351 \AA$ ) for the cationic system 136a in comparison to $\mathrm{Pt}-\mathrm{Cl}(2.308 \AA)$ in $\mathrm{K}_{2} \mathrm{PtCl}_{4}$. Thus, the cationic phosphine possesses a stronger trans effect, which should enables easy abstraction of the $\mathrm{Cl}^{-}$anion during catalysis. This strong trans influence is caused by the short bond distance between Pt and P1 (2.219 Å), probably due to electrostatic interactions between the cationic phosphine and the anionic platinum atom. This short distance facilitates $\pi$-back donation due to the more efficient orbital overlap and therefore, it renders the metal more $\pi$-acidic and more reactive in catalysis.

Figure 15: molecular structure of $\mathrm{K}_{2} \mathrm{PtCl}_{4}$ and 136 in the solid state. Hydrogen atoms and cations are omitted for clarity. Anisotropic displacement parameter are shown at 50\% probability level.

### 7.2.2 Synthesis of gold complexes

Gold complexes were prepared by reaction of $\mathrm{Me}_{2} \mathrm{~S} \cdot \mathrm{AuCl}$ with the desired ligand in DCM for one to three hours. The desired gold complexes 137a-c,f-g were obtained in excellent yields ( $97-99 \%$ ) independently of their stereo electronic properties. Only the preparation of the gold complex 137e proved due to the high reactivity of the corresponding phosphine to be more challenging ( $40 \%$ yield).

137c, 99\%

137f, 40\%

Scheme 59: synthesis of gold complexes 137a-e.

### 7.3 Applications in catalysis

With all these complexes in hand, we next examined the possible application of platinum complexes 136a and $\mathbf{b}$ in catalysis. We chose the hydroarylation of propargyl ether 138 to chromene 139 published by Sames et al. ${ }^{103}$ As they showed, up to $32 \%$ conversion can be obtained with the more $\pi$-acidic $\mathrm{PtCl}_{4}$, while the less $\pi$-acidic $\mathrm{PtCl}_{2}$ only converts $3 \%$ of the starting material to the desired product. Because the nucleophile is an arene unit, which is a relatively bad nucleophile, the rate determining step should be the nucleophilic attack. Both arguments predict higher reactivity with electron poor phosphines like the newly prepared pyridinium phosphines.

While all tested ligand are stable within the examined timeframe (linear regression) only highly $\pi$-acidic phosphines are reactive enough to fully convert the starting material to the desired chromene 139. Classical ligands like $\mathrm{PPh}_{3}$ or $\mathrm{P}\left(\mathrm{C}_{6} \mathrm{~F}_{5}\right)_{3}$ only increase the conversion up to $10 \%$. Apart from the tuning of the $\pi$-acidity of the ligand, that coordinate the platinum metal, also the acidity of the metal itself can be enhanced to promote the reaction. Using platinum at a higher oxidation state $\mathrm{Pt}(\mathrm{IV}) \mathrm{Cl}_{4}$ lead to $30 \%$ within the examined timeframe. However, the highly $\pi$ acidic pyridinium ligands promote much faster reactions. Full conversions are obtained within minutes. The non-substituted pyridinium phosphine platinum complex 136a leads to full

[^35]conversion within 25 min., while the $\mathrm{CF}_{3}$-substituted pyridinium phosphine platinum complex 136b accelerates the reaction rate even more, resulting in 100\% conversion after 2 mins.

Figure 16: ligand effect on the Pt-catalysed hydroarylation of propargyl aryl ether 138 to chromene 139. Reagents and conditions: a) 138 ( 0.05 m ), Pt precatalysts ( $2 \mathrm{~mol} \%$ ), $\mathrm{AgSbF}_{6}(2 \mathrm{~mol} \%),\left(\mathrm{CH}_{2}\right)_{2} \mathrm{Cl}_{2}, 80^{\circ} \mathrm{C}$. Conversions determined by gas chromatography.

To further prove the generality of this effect, we performed an additional platinum catalysis. In this case enine 140 was converted to cyclobutene $141 .{ }^{104}$ We chose this transformation from Fürstner et al. ${ }^{104}$ as it is known to respond to the strong $\pi$-acceptor properties of the ligands. In comparison to classical ligands $\mathrm{PPh}_{3}\left(2 \%\right.$ conversion), $\mathrm{P}(\mathrm{OPh})_{3}(15 \%$ conversion) or even the archetypical $\pi$-acceptor ligand CO ( $20 \%$ conversion), our cationic ligands vastly outperformed the known reaction rates and could achieve full conversion within 5 min . (with catalyst 136a) or even within 2 min . (with the $\mathrm{CF}_{3}$-substituted analogue 136b). This proves the superiority of our newly designed ligand class.

[^36]

Figure 17: ligand effect on the Pt-catalysed cycloisomerisation of enyne 140 to cyclobutene 141. Reagents and conditions: 140 (0.05 M), Pt precatalysts ( $2 \mathrm{~mol} \%$ ), $\mathrm{AgSbF}_{6}(2 \mathrm{~mol} \%),\left(\mathrm{CH}_{2} \mathrm{Cl}\right)_{2}, 80^{\circ} \mathrm{C}$. Conversions determined by gas chromatography.

Apart from platinum catalysis phosphine ligands find a lot of applications in gold catalysis as well. Therefore, we next tested the effect of our ligands in gold catalysis, performing an intermolecular hydroarylation of phenyl acetylene at $60^{\circ} \mathrm{C}$ in 1,2-dichloroethane.

Figure 18: ligand effect on the Au-catalysed hydroarylation of alkyne 143 with arene 142. Reagents and conditions: 143 $(0.05 \mathrm{~m}), 142\left(4\right.$ equiv; 0.2 m ), Au' precatalysts ( $5 \mathrm{~mol} \%$ ), $\mathrm{AgBF}_{4}$ or $\mathrm{AgSbF}_{6}(5 \mathrm{~mol} \%),\left(\mathrm{CHCl}_{2}\right)_{2}, 60^{\circ} \mathrm{C}$. Conversions determined by gas chromatography.

This reaction was reported by Reetz et al. ${ }^{105}$ with a catalytic mixture of $\mathrm{AuCl}_{3}$ and 3 equiv. $\mathrm{AgSbF}_{6}$ to generate highly electrophilic gold(III) cations. Our newly developed cationic phosphines should enable gold(I) to be tuned as highly electrophilic as the reported gold(III) catalysts. Therefore, we tested the effect of our pyridinium phosphines in the mentioned transformation.

As expected, with the classical gold phosphine systems $\left(\mathrm{PPh}_{3} \mathrm{AuCl}\right.$ and $\left.\mathrm{P}(\mathrm{OPh})_{3} \mathrm{AuCl}\right)$ very low conversions were obtained, because the electrophilicity of the gold atom is not high enough to promote the intermolecular attack of mesitylene towards phenylacetylene. Using the pyridinium substituted phosphine gold complex 137a, moderate yields (up to $25 \%$ ) were

[^37]achieved within 60 mins; already reaching the high turnovers of gold(III) chloride (up to $27 \%$ ). Enhancing the $\pi$-acidity of the phosphine further (using the $\mathrm{CF}_{3}$ substituted phosphine 137c) $45 \%$ conversion to the desired product 144 could be obtained. This high reactivity was surpassed by the dicationic cyclopropenium system 62a, which lead to a conversion of $60 \%$ within 60 mins. The best conversion (70\%) observed, was achieved with the highly electrophilic polyfluorinated pyridinium phosphine gold complex 137e. However, in all the cases - even with the commercial systems - a major drawback is the deactivation of the catalytic mixtures when prolonged reaction times are necessary. Probably this is caused by decomposition of the gold complexes towards gold nanoparticles and free phosphines.

Next we examined the effect of the counter ions used during catalysis employing the trifluoromethyl substituted pyridinium phosphine 137c. While the tetrafluoroborate anion is accounted as non-coordinating, the hexafluoroantimonate anion is even less coordinating, thus, it should lead to slightly increased reaction rates. As expected the reaction rate is significantly lower with two $\mathrm{BF}_{4}{ }^{-}$anions ( $15 \%$ ), while the substitution of one $\mathrm{BF}_{4}{ }^{-}$unit towards a $\mathrm{SbF}_{6}{ }^{-}$anion increases the conversion: $\mathrm{A} 1: 1$ mixture of $\mathrm{BF}_{4}{ }^{-}$and $\mathrm{SbF}_{6}$ yields $45 \%$ conversion, while two $\mathrm{SbF}_{6}-$ units convert up to $65 \%$ of the starting material to the product, confirming a strong effect of the used counter anions. Another rational to understand the effect of the employed counter anions consist on considering the enhanced solubilities achieved with larger, less coordinating anions in polar solvents.

Figure 19: counter anion effect on the Au-catalysed hydroarylation of alkyne 143 with arene 142. Reagents and conditions:
142 ( 0.05 m ), 143 (4 equiv; 0.2 m ), Au' precatalysts ( $5 \mathrm{~mol} \%$ ), $\mathrm{AgBF}_{4}$ or $\mathrm{AgSbF}_{6}(5 \mathrm{~mol} \%),\left(\mathrm{CH}_{2} \mathrm{Cl}\right)_{2}, 60^{\circ} \mathrm{C}$. Conversions determined by gas chromatography.

Comparison of the kinetic data for the three examined reactions shows good agreement of the measured oxidation potentials by cyclic voltammetry and the reactivity during catalysis. In all cases, a higher oxidation potential led to an increased reactivity independent of the examined reaction, allowing predictions of the reactivity of new compounds by simple measurement of their oxidation potentials.

Besides the pyridinium phosphine and the aforementioned mono-, di- or tricationic cyclopropenium phosphines, we previously reported the synthesis of bis-piperidinium-, imidazolinium- and amidinium phosphines. ${ }^{75}$ While the formamidinium system 65 and the dihydroimidazolium phosphine 64a show lower oxidation potential and therefore should possess a lower reactivity during catalysis, the amidinium phosphine 145 shows an even higher oxidation potential, indicating that improved reactivity might be obtained.

Scheme 60: oxidation potential of cationic phosphines 64a, 65, 137c and 145.
To prove the predicted reactivities, we then applied the aforementioned phosphines in the hydroarylation of propargyl ether 138 to chromene 139 as well.

Figure 20: ligand effect on the Pt-catalysed hydroarylation of propargyl aryl ether 138 to chromene 139. Reagents and conditions: a) 138 ( 0.05 m ), Pt precatalysts ( $2 \mathrm{~mol} \%$ ), $\mathrm{AgSbF}_{6}$ ( $2 \mathrm{~mol} \%$ ), $\left(\mathrm{CH}_{2} \mathrm{Cl}\right), 80{ }^{\circ} \mathrm{C}$. Conversions determined by gas chromatography.

The observed kinetic is in excellent agreement with the corresponding oxidation potentials as well as their calculated respective frontier orbital, which increase from formamidinium- over dihydroimidazolium- to amidinium-phosphine. ${ }^{73}$

Figure 21: frontier orbitals of commercial and cationic phosphines.
Apart from the applications in gold and platinum catalysis further coordination chemistry to other metals sources was tested. As described before, we could successfully coordinate rhodium sources and use the corresponding complexes for the evaluation of the electronic properties of the corresponding phosphines. Applying this knowledge we also examined the coordination of cationic pyridinium phosphine $\mathbf{1 2 4 a}$ and $\mathbf{1 2 4 b}$ to $\left[\mathrm{Rh}(\mathrm{COD}) \mathrm{Cl}_{2}\right.$ and were pleased to see, that the corresponding complexes 150a and 150b were obtained in excellent yields.

Scheme 61: synthesis of the rhodium complexes 150a-b.

We also tested the coordination chemistry of pyridinium ligands to $\mathrm{Pd}(\mathrm{II})$ sources. The corresponding complexes 151a-c were obtained in excellent yields.

Scheme 62: synthesis of palladium complexes 151a-c
Crystallisation of palladium complex 151c confirmed the square planar geometry around the palladium centre ( $\angle \mathrm{Cl} 1 \mathrm{PdCl} 1^{*}=180^{\circ}$ and $\angle \mathrm{P} 1 \mathrm{PdP1}^{*}=180^{\circ}$ ) as well as the trans-assembly of the two phosphine residues.

Figure 22: Molecular structure of 151c in the solid state. Hydrogen atoms and cations are omitted for clarity. Anisotropic displacement parameter are shown at 50\% probability level.

Next we tested the newly prepared palladium complexes in direct arylation reported by Itami et al. ${ }^{106}$ selectively phenylating thiophene 152 at the $\beta$-position.

This reaction is reported to be faster by employment of electron poor phosphine ligands and therefore cationic ligands should be beneficial for this transformation. To minimize the lower $\alpha / \beta$ selectivity caused by cationic ligands we changed the silver salt from $\mathrm{Ag}_{2} \mathrm{CO}_{3}$ to $\mathrm{AgBF}_{4}{ }^{107}$ obtaining good $\beta$ selectivity with our cationic phosphines as well.

As shown by kinetic experiments in the presence of weak $\pi$-accepting ligands like $\mathrm{PPh}_{3}$ only traces of the starting material are converted to the desired product, while stronger $\pi$-acidic ligands like $\mathrm{P}(\mathrm{OPh})_{3}$ or $\mathrm{P}\left(\mathrm{OPrF}_{6}\right)_{3}$ already convert up to $30 \%$ of the starting material within six hours. Using the cationic palladium complexes, we could further accelerate the reaction to gain conversion of up to $55 \%$ within 6 hours. Unfortunately the catalytic mixture lost its reactivity with prolonged reaction times., probably caused by degradation of the catalyst.

[^38]

Reagents and conditions: 152 ( 0.5 M ), $\mathbf{1 5 3}$ ( 0.75 M ), palladium precatalyst ( $5 \mathrm{~mol} \%$ ), $\mathrm{AgBF}_{4}(1.5 \mathrm{eq}), \mathrm{Phl}(1.5 \mathrm{eq}), \mathrm{m}-X y l e n e, 130^{\circ} \mathrm{C}$. Conversions determined by gas chromatography.

### 7.4 Applications of other cationic ligands in catalysis

We next examined, if the reaction conditions of the hydroarylation of 138 to chromene 139 could be tuned to allow lower reaction temperatures - possibly enhancing the functional group tolerance - and a lower catalyst loading. Decreasing the temperature from $80^{\circ} \mathrm{C}$ to rt and reducing the catalyst loading to $1 \mathrm{~mol} \%$ still allowed the reaction to be finished within 60 mins for the more reactive catalytic systems (64a, 65, 126a, 145). Whilst the amidinium system only achieved $5 \%$ conversion, the dihydroimidazolium and the pyridinium substituted catalytic mixtures converted up to $90 \%$ within 60 min . The amidinium system turned out to be the most reactive system (full conversion within 10 mins ). For the imidazolinium and the pyridinium systems a sigmoid correlation (S- shape) ${ }^{108}$ is observed, indicating low solubility of the precatalyst (lower reaction rate at the beginning), high reactivity once all catalyst is activated and diffusion controlled lowered reactivity at the end of the reaction.

We tried to further improve the reaction conditions for the most reactive catalyst system 145 lowering the catalyst loading to $0.5 \mathrm{~mol} \%$, however under these reaction conditions only $93 \%$ conversion was obtained.

Figure 24: ligand effect on the Pt-catalysed hydroarylation of propargyl aryl ether 35 to chromene 36. Reagents and conditions: a) 35 ( 0.05 m ), Pt precatalysts ( $1 \mathrm{~mol} \%$ ), $\mathrm{AgSbF}_{6}$ ( $1 \mathrm{~mol} \%$ ), $\mathrm{CH}_{2} \mathrm{Cl}_{2}$, rt. Conversions determined by gas chromatography.

[^39]

Scheme 64: platinum catalysed hydroarylation at 0.5 mol\% catalyst loading
Hydroaminations ${ }^{109}$ and hydroalkoxylations ${ }^{110}$ reported by Wiedenhofer et al. were also investigated. However, in the hydroalkoxylation of alcohol 146 to ether 147 instead of the expected trend of reactivity all catalyst systems performed equally well, indicating a case of hidden acid catalysis is faced. We therefore tested triflic acid as catalyst, which converted the examined systems as good as the $\pi$ - acids into the product. Further we noted, that the addition of a sterically hindered none coordinating bases stops the reaction, which also corroborates the hypothesis of hidden acid catalysis. Instead of activating the alkene function of molecule 146 as a $\pi$ acid the gold complexes are coordinated by the hydroxyl group and act as a $\sigma$ acid. The released proton then catalyses the hydroalkoxylation, resulting in nearly the same reactivity for all gold complexes.

[^40]
## Hendrik Tinnermann

Figure 25: ligand effect on the hydroalkoxylation of alcohol 146 to tetrahydrofurane 147. Reagents and conditions: 146 ( 0.05 M ), Au precatalysts (1 mol\%), $\mathrm{AgSbF}_{6}(1 \mathrm{~mol} \%),\left(\mathrm{CHCl}_{2}\right)_{2}, 70^{\circ} \mathrm{C}$. Conversions determined by gas chromatography.

In the exo cyclisation of alkynyl biphenyl system 148 to fluorene 149 the tested gold complexes $\mathrm{PPh}_{3} \mathrm{AuCl}, 48-\mathrm{AuCl}$ and $49-\mathrm{AuCl}$ performed equally well. The additional ester function reduces the electron density of the alkyne function and therefore instead of $\pi$ activation of the alkyne $\sigma$ activation is again observed. The gold complex coordinates the ester function and generates a partial positive charge at the alkyne, this results in the exo cyclisation of 148.

Figure 26: ligand effect on the hydroalkoxylation of biphenyl system 148 to fluorene 149. Reagents and conditions: 148 ( 0.05 M ), Au precatalysts (1 mol\%), $\mathrm{AgSbF}_{6}(1 \mathrm{~mol} \%),\left(\mathrm{CHCl}_{2}\right)_{2}, 70^{\circ} \mathrm{C}$. Conversions determined by gas chromatography.

## 8 Synthesis, structure and applications of arene substituted pyridinium phosphines

After the successful application of N -alkyl phosphine in catalysis, we tried to further improve this system. As mentioned before the catalytic mixtures of gold $(\mathrm{I})$ precursors and the pyridinium phosphines undergo slow decompositions. Therefore we aimed to develop more stable pyridinium substituted phosphines.

One way to enhance the stability of the reactive gold(I)-catalyst is as shown by Echavarren ${ }^{111}$, $\mathrm{Xu}^{46}$ and others to introduce a biphenyl unit to the phosphorus atom, allowing a secondary stabilizing interaction between the gold atom and the additional arene ring. For example biphenyldiphenylphosphine gold triflate does not decompose to $\mathrm{Au}^{0}$ and bisligated gold triflate within 200 h , while triphenylphosphine gold triflate decomposes up to $80 \%{ }^{46}$ Furthermore the beneficial effect of biphenyl gold catalyst was shown along a vast amount of transformation in gold chemistry. For example as reported by Echavarren in the methoxycyclisation of enyne the use of XPhos as ligand allowed long reaction times and high yields ( $18 \mathrm{~h}, 94 \%$ ), while more reactive ligands like $\mathrm{AsPh}_{3}$ (48\%) or the classically used $\mathrm{PPh}_{3}$ (70\%) only gave lower yields of the desired product within the same time. ${ }^{112}$

The mentioned biphenyl unit is as well advantageous in palladium chemistry: Buchwald et al. showed, that the presence of the biphenyl unit facilitates the oxidative addition, as only one ligand can coordinate the $\operatorname{Pd}(0)$ generated, and at the same time facilitates the reductive elimination process through the steric bulk employed. Furthermore, the additional aryl unit retards oxidation by $\mathrm{O}_{2}$ and stabilises the Pd centre through secondary interactions. The large substituents at the additional arene unit themself avoid the cyclometalation of the palladium centre.

All this beneficial effects and the broad applications of the structural related and commercial phosphine ligand SPhos (22) and XPhos (23) encouraged us to attempt to synthesize a related class of pyridinium phosphines 168. This should be achieved through the introduction of an aryl unit to the nitrogen of the pyridinium generation N -aryl substituted pyridinium phosphines.

[^41]

Figure 27: Development of arene substituted pyridinium phosphines.

### 8.1 Strategies for the synthesis of N -aryl substituted pyridinium phosphines

### 8.1.1 Direct N -arylation

The synthesis of 1-aryl substituted pyridinium phosphines was accomplished in three steps. Ullmann coupling of pyridone 130 with phenyl iodide gave the corresponding 1-phenylpyridone (133) in excellent yield ( $95 \%$ ). ${ }^{113}$ After chlorination with oxalyl chloride to obtain the 2-chloro-1-phenyl-pyridinium salt 134 in good yield (71\%) N -aryl pyridinium phosphine 124j was prepared by nucleophilic aromatic substitution with diphenylphosphine in good yield (71\%).

Scheme 65: preparation of 134 by Ullmann coupling and chlorination with oxalyl chloride.

Similarly to the N-phenylation of the pyridinium ring, we tried to introduce the mesityl or the dimethoxy arene unit by Ullmann coupling with pyridone and the corresponding aryl iodide. However, due to the increased steric demand no product formation was observed. Direct coupling of chloropyridine 126a and the corresponding iodide at reaction temperature of up to $140^{\circ} \mathrm{C}$, either heating in an oil bath or by $\mu$ wave irradiation, failed. The same occurs when the coupling is attempted with dimesityl iodonium salt 172. These limitations most likely are caused

[^42]by the vastly increased steric bulk of the employed iodide in comparison to phenyl iodide. Therefore we decided to attempt another approach.

Scheme 66: attempts for the direct preparation of arene substituted pyridinium phosphines.

### 8.1.2 Pyridinium salt functionalization

Due to the limitations, an alternative synthetic strategy was considered. After preparation of the corresponding precursor $\mathbf{1 7 5}$ in $73 \%$ yield, using the well-established Zincke reaction, ${ }^{114}$ we could prepare the arene substituted pyridinium salts 176a-c in moderate to good yields (34$81 \%$ ). This reaction works with highly sterically encumbered amines like 2,6 -diisopropylaniline or even $2,4,6$-triisopropylaniline. However, further increasing the steric bulk at the pyridinium core (employing 3,5 -lutidiniumsalt 178) precludes the Zincke reaction to take place; the nucleophilic substitution of the chloride with the corresponding amine was observed. This side reaction can easily be understood considering the high steric bulk at the $\alpha$-position of the pyridinium ring. Hence, the nucleophilic attack occurs at the $\alpha$-position of the pyridinium ring (at the ipso position of the lower ring).

[^43]

Scheme 67: preparation of pyridiniumsalts 176a-c.

Scheme 68: attempts of the Zincke reaction of lutidiniumsalt 178.
After the preparation of the pyridinium salts 176a-c, we next functionalized the compounds to be able to introduce the phosphine at the $\alpha$-position. Thus, we first performed an ortho functionalization to the corresponding thiopyridone 188a-c by deprotonation of 176a-c with LiHMDS and in situ trapping of the formed carbene with $\mathrm{S}_{8}$ (64-70\%). Afterwards, we converted the thiopyridone into the chloro pyridinium salt that should easily undergo nucleophilic aromatic substitution reaction with different phosphines. Consecutive chlorination with oxalylchloride in the presence of dimethylformamide led to the formation of chloro pyridinium salts 189a-c in excellent yields (93-97\%). Scale up of the just mentioned sequence to gram scale (up to 5 g ) was possible for all substitution patterns up to the chloro pyridinium salt stage.

$176 a, R^{1}=R^{2}=\mathrm{Me}: 81 \%$
$176 \mathrm{~b}, \mathrm{R}^{1}=\mathrm{OMe}, \mathrm{R}^{2}=\mathrm{H}: 43 \%$
$176 \mathrm{c}, \mathrm{R}_{1}=i \mathrm{Pr}, \mathrm{R}_{2}=\mathrm{H} ; 34 \%$

188a, $R^{1}=R^{2}=\mathrm{Me}: 64 \%$

188c, $\mathrm{R}_{1}=i \mathrm{Pr}, \mathrm{R}_{2}=\mathrm{H} ; 74 \%$

189a, $R^{1}=R^{2}=\mathrm{Me}: 93 \%$
189b, $R^{1}=O M e, R^{2}=H: 97 \%$
189c, $\mathrm{R}_{1}=i \mathrm{Pr}, \mathrm{R}_{2}=\mathrm{H} ; 94 \%$

Scheme 69: Synthesis of the chloropyridinium salts.

With the chloro pyridinium salts in hand, we then commenced introducing different phosphines by direct phosphination with either diphenylphosphine (50-69\%) or dicyclohexylphosphine (47-
$69 \%$ ) under microwave irradiation for 12 h at $140^{\circ} \mathrm{C}$ in THF, or by deprotonation of the polyfluorinated phosphine and followed by direct condensation (190a-h, 45-70\%). Unfortunately, the introduction of $\mathrm{tBu}_{2} \mathrm{PH}$ could not be achieved under the chosen reaction conditions.

Overall this reaction sequence allowed fast, scalable and direct access to the arene substituted pyridinium phosphines in a five step sequence with overall yields between $8.1 \%$ (190a) and 24.6\% (190b).

Scheme 70: Synthesis of pyridinium phosphines.
After the successful preparation of the new pyridinium phosphines, we were able to crystallize a few examples to confirm the expected connectivity. This enabled us to check if the phosphorus lone pair, even in the sterically demanding environment, is available for coordination.

## Hendrik Tinnermann

190d

Figure 28: schematic representation and numbering of cationic arene substituted phosphine gold complexes. Solid state structures of phosphines 190 b, $c, d, f$ and $\boldsymbol{h}$. Hydrogen atoms and anions are omitted for clarity. Anisotropic displacement parameter are shown at 50\% probability level.

| Compound | Phosphine | $\mathrm{d}(\mathrm{P}-\mathrm{C} 1)[\AA]$ | $\mathrm{d}(\mathrm{P}-\mathrm{C} 12)[\mathrm{A}]$ | $\mathrm{d}(\mathrm{P}-\mathrm{C} 18)[A \cap]$ | pyramidalization [ ${ }^{\circ}$ ] |
| :---: | :---: | :---: | :---: | :---: | :---: |
| 190b | MesPolyCF3 | 1.849 | 1.831 | 1.829 | 308.02 |
| 190c | $\mathrm{DiOMePyPPh}_{2}$ | 1.850 | 1.836 | 1.821 | 305.71 |

| 190f | MesPyCy2 | 1.863 | 1.867 | 1.865 | 303.57 |
| 190h | $\mathrm{Pr}_{2} \mathrm{PyPCy} y_{2}$ | 1.860 | 1.877 | 1.855 | 303.96 |
| 124a | MePyPPh2 | 1.855 | 1.826 | 1.824 | 304.87 |
| 124e | MePyCy2 | 1.858 | 1.873 | 1.849 | 303.79 |
| 46a | CyclopropPPh2 | 1.814 | 1.834 | 1.831 | 303.67 |

Table 5: important distances and angles in the solid state structure of phosphines.
Despite the vastly increased steric bulk comparing for example the methyl substituted pyridinium phosphine 124a and the mesityl substituted phosphine 190d, only minor differences in bond angles and bond distances are observed ( $1.855 \AA$ Å 124a vs. $1.850 \AA$ for 190d and $304.91^{\circ}$ vs. $304.87^{\circ}$ ). Furthermore, the high degree of pyramidalization (303.57-308.02 $)$ present in all phosphines indicates its availability to coordination.

### 8.2 Synthesis of gold complexes

Next the coordination chemistry of phosphines 124j and 190a-f was examined. Hence, we prepared the corresponding gold complexes by simple ligand exchange reaction with $\mathrm{Me}_{2} \mathrm{~S} \cdot \mathrm{AuCl}$. In all cases the gold complexes were obtained in moderate (137d, 68\%) to excellent yields (191a-f, 89-99\%).

191b, 98\%

191d, $98 \%$

191f, $96 \%$

Scheme 71: synthesis of gold complexes 137d and 191a-f.
Compound 137d was crystallized and its structure was in agreement with our expectations. The solid state structure shows a secondary interaction between the gold atom and the C11 atom of the arene ring ( $3.14 \AA$ ), which is different to the neutral equivalent $\mathrm{Cy}_{2} \mathrm{JohnPhos}$, which also shows a secondary gold interaction, but to the carbon in ipso position of the arene ring $(3.136 \AA)^{115}$. The differences arise from the presence of the cationic charge next to carbon C 7 , which lowers the electron density of this carbon and therefore is less prone to coordination.

[^44]

Figure 29: molecular structure of $\mathrm{Cy}_{2} b i \mathrm{PhAuBr}$ and $137 d$ in the solid state. Hydrogen atoms and anions are omitted for clarity. Anisotropic displacement parameter are shown at 50\% probability level.

To be able to compare the electronic and steric influence and the secondary interaction with the gold atom of the additional arene ring, we crystallised and analysed the five gold complexes (191a, b, d and 191f) by x-ray diffraction techniques. This allowed us to compare the influence of the additional cationic charge in comparison to their neutral congeners and, furthermore, to assess the effect of the additional steric bulk on the structure of the Au-precatalyst.

Figure 30: solid state structures of $\mathrm{Cy}_{2} X P h o s{ }^{115}$ and pyridinium phosphine gold complexes 191a, $\boldsymbol{b}$, $\boldsymbol{d}$ and 191f. Hydrogen atoms, disorder and cations are omitted for clarity. Anisotropic displacement parameter are shown at 50\% probability level.

In all crystallised complexes a secondary interaction between the pyridinium arene unit and the gold atom is present. Although the bond distances in these complexes are slightly different (3.092-3.193 Å), they all are shorter than the corresponding sum of the van-der-Waals radii ( $3.360 \AA$ Å). The nature of the interaction differs depending on the substitution pattern. While usually the main interaction occurs towards the ortho carbon of the pyridinium arene substituent, in gold complex 191a and 191f the nature of the interaction differs. In complex 191a the interaction occurs between the oxygen and the gold atom and in gold complex 191 f the closest arene gold contact aligns at the ipso carbon of the pyridinium arene ( 3.149 A ). All bond distances are comparable to literature known interactions between gold atoms and biphenyl units (XPhos: $3.126 \AA$, CyJohnPhos: $3.136 \AA$ A ; compare Gray et al. ${ }^{115}$ ) and therefore, during catalysis the pyridinium complexes might show improved catalyst stabilities as well.

### 8.3 Applications in gold catalysis

We next examined the effect of the newly prepared ligand system in a gold catalysed reaction. We chose a gold catalysed [2+2] cycloaddition reported by Mukai ${ }^{166}$ in 2015. This transformation is accelerated by the use of very bulky catalytic systems like XPhos and as well by the use of the Z-type, electron poor gold complex as described by Mukai (199). However none of the reported ligand could reach full conversion even in a timeframe of 24 hours. Therefore, we decided to test our ligand system, which combines the bulk and reactivity needed in this cycloaddition.

Scheme 72: effect of the catalytic mixtures toward to the [2+2] cycloaddition reported by Mukai et al.

First we performed studies under the same reaction conditions as Mukai reported and checked them by NMR (Figure 31). However, in all the performed NMR experiments no proper of the reaction mixtures could be ensured during the measurement. Despite these problems already by NMR studies a clear trend can be observed. The commercial ligand gold complexes of SPhos, $\mathrm{PPh}_{3}$ and XPhos already reached low conversions ( $2 \%, 7 \%$ and $15 \%$ ) within 80 minutes, while our pyridinium system converted already $40 \%$ within the same timeframe, illustrating the enhanced reactivity introduced by the additional positive charge already at this stage.

Figure 31: ligand effect in the gold catalysed cycloaddition of enine 192 to cyclobutene 193, conversion determined by ${ }^{1} \mathrm{H}$ $\mathrm{NMR}, 2 \mathrm{~mol} \%$ [ Au ], $2 \mathrm{~mol} \% \mathrm{AgSbF}_{6}, 0.1 \mathrm{M}$ in $\mathrm{CD}_{2} \mathrm{Cl}_{2}$ at rt.

Not only the $\pi$-acceptor properties of the applied ligand are important, the bond strength between the used ligand and the gold atom and the before mentioned steric protection of the gold atom needs to be considered as well.

Figure 32 shows performing the reaction in a classical laboratory setup, that increasing the steric bulk from a methyl to a mesityl group heads to an improved reactivity ( $10 \%$ higher conversion, 137a vs. 191d). This additional reactivity stems from the increased stability of gold complex 191d, caused by the aforementioned arene gold interaction. The stability of the gold phosphine complex can be further increased employing more $\sigma$-donating phosphines. Cyclohexyl substituted phosphines 191 f led to full conversion, while phenyl substituted phosphine 191d and polyfluorinated phosphine 191b led to $25 \%$ and $50 \%$ conversion.

Figure 32: ligand effect in the gold catalysed cycloaddition of enine 192 to cyclobutene 193, 2 mol\% [Au], 2 mol\% AgSbF ${ }_{6}$, 0.1 M in $\mathrm{CH}_{2} \mathrm{Cl}_{2}$ at rt; conversion determined by gas chromatography versus an internal standard

While the silver salt alone did not convert enine 192 to cyclobutene 193, well established ligands for gold catalysis like $\mathrm{PPh}_{3}$, SPhos and XPhos performed poorly within the examined timeframe (up to $25 \%$ within 90 min.), compare Figure 33. However, the different steric and electronic interacting effects can easily explain the observed behaviour. While more $\pi$-acidic ligand like triphenylphosphite perform at a significantly higher rate in the first 20 min of the transformation their reactivity ceases due to their lower stability with prolonged reaction times. Therefore on the other hand also good result can be obtained employing more stable gold complexes SPhosAuCl and XPhosAuCl with arene gold interactions, which show an almost linear correlation of the observed reactivity with time only offset by a low reaction rate. Combining the enhanced reactivity of good $\pi$-acceptor ligands and at the same time enhancing the steric protection of the gold atom and therefore the stability of the catalytically active species, the reaction rate could greatly be improved - pyridinium phosphine complexes 191e and 191 f led to full conversion towards the cyclobutene 193 within 90 min .

It should be noted, that further prolonged reaction times lead to decomposition of the product and starting material in all examined cases and after 24 h of reaction time, only traces of the desired product could be found.

Figure 33: ligand effect in the gold catalysed cycloaddition of enine 192 to cyclobutene 193, 2 mol\% [Au], 2 mol\% AgSbF6, 0.1 M in $\mathrm{CH}_{2} \mathrm{Cl}_{2}$ at rt; conversion determined by gas chromatography versus an internal standard

After this promising results, we then lowered the catalyst loading to $0.2 \mathrm{~mol} \%$ and still achieved full conversion within 16 hours ( $95 \%$ isolated yield), once again demonstrating the high reactivity, as well as stability of the newly developed cationic arene substituted pyridinium phosphine 191e.

Scheme 73: Cycloaddition of enine 192 to cyclobutene 193 under optimized conditions using 0.2mol\% X, 0.2mol\% AgSbF $_{6}$ in DCM for 16 hours at $r t$.

### 8.4 Applications in palladium chemistry

After these highly encouraging results we aimed to find other catalytic applications in areas different to $\pi$-acid catalysis. Hence, we decided to examine the use of our developed ligand in palladium chemistry.

In general in palladium chemistry highly $\pi$-accepting ligands are rarely used, however they should be able to facilitate a number of steps of a general catalytic cycle. For example palladium catalysed $\mathrm{C}-\mathrm{H}$ activations might be an interesting area to test our ligands. The catalytic cycle for a C-H activation can consist of oxidative addition, precoordination, electrophilic reaction, base promoted deprotonation and reductive elimination. The oxidative addition to palladium systems bearing one of our cationic ligands is going to be more difficult, because a palladium(II) state has to be generated starting from an already cationic palladium( 0 ) centre. On the other hand the electrophilic substitution occurs at a faster rate, because for the described $\mathrm{C}-\mathrm{H}$ activation sequence the generated palladium(II) centre is stabilized by two organic residues, instead of like in case of cross coupling reactions by one and a halogen atom. Our ligand influence the base assisted deprotonation also to our benefit. The deprotonation from a highly cationic intermediate is faster and easier, therefore less basic bases can most likely be employed. Last the reductive elimination (for a number of palladium catalysed reaction rate determining) occurs at a higher rate, regenerating the palladium(0) centre and minimizing partial charges.

Scheme 74: mechanism of a C-H activation based on an electrophilic substitution.
To compensate the more difficult oxidative addition, when cationic ligands are employed, we decided to use aryl iodides instead of the classically employed aryl bromides and chlorides. Due to the weaker aryl halide bond these undergo oxidative addition with relative ease.

This promising assessment of cationic phosphines promoted our group to test our ligands in palladium chemistry. However, for the cyclopropenium substituted phosphines instead of the coordination product the insertion of palladium between the phosphorus atom and the cyclopropenium moiety was observed. ${ }^{76}$

Scheme 75: synthesis of palladium complexes 301 and 302.
Nevertheless, we tried to prepare the corresponding palladium complexes of the newly prepared pyridinium phosphines 190a, b and c. Unfortunately no coordination product was obtained for pyridinium phosphines 190a, band $\mathbf{c}$ and different palladium sources. Luckily no
insertion product was obtained, showing that in general pyridinium phosphines might find applications in palladium catalysed reactions.

Scheme 76: coordination attempts of different $\operatorname{Pd}(0)$ sources.
Therefore, we decided to deliver the palladium(0) species in situ during catalysis, starting from a palladium(II) source as described by Buchwald et al. ${ }^{117}$ Beginning from the corresponding palladium(II) amino biphenyl system 194, the palladium(0) phosphine complexes 195 is formed under catalytic conditions either by thermal or base promoted reductive elimination of the ammonium biphenyl mesylate.

Scheme 77: reductive elimination leading to catalytic active palladium(0) species as reported by Buchwald.
Analogously to Buchwald's report, we prepared the corresponding palladium(II) complexes in THF, however, due to fast thermal reductive elimination of the amino biphenyl unit we had to perform this reaction at $-20^{\circ} \mathrm{C}$ yielding the corresponding pyridinium phosphine palladium complex 196 after an anion exchange with $\mathrm{NaSbF}_{6}$ in only moderate yield ( $54 \%$ over two steps). The same system was prepared for the SPhos ligand ( $51 \%$ over two steps).

[^45]

191e

196, $54 \%$

22

THF, rt, 1 h

197, 51\%

Scheme 78: preparation of palladium(II) complexes 196 and 197.
To be able to compare the reactivity of SPhos and the pyridinium phosphine with classical mono coordinating ligands we prepared the triphenylphosphine and triphenylphosphite palladium complexes 198 and 199 in good yields (88 and 85\%) analogously to literature reports. ${ }^{117}$

198, 88\%

Scheme 79: preparation of palladium complexes 198 and 199.

With this complexes in hand, after several attempts, we were able to crystallize complex 196 from THF and $n$-pentane by diffusion at $-20^{\circ} \mathrm{C}$. The solid state structure shows two independent units both possessing a strong interaction between the arene ( $C 1-\mathrm{Pd}_{\text {(averaged) }}$ : $2.357 \AA$ ) and the palladium centre, resulting in a distorting of the aryl pyridinium plane ( $\varphi(N$-Ary $)$ averaged $=151^{\circ}$ ). Because the analogue complexes derived from SPhos were not crystallised and no direct comparison was possible, we compared the solid state structure of our complex 196 with the closest relative, complex 200. ${ }^{68}$ In our newly prepared palladium complex 196 the bond distance ( $2.357 \AA$ A) is already shorter than in complex 200 (C1-Pd: $2.447 \AA$ ), while in our palladium complex a stronger bending away from the ideal $180^{\circ}$ is present $\left(\varphi_{(N-A r y)}=151^{\circ}\right.$ to Buchwald's $\varphi(C-$-ary $\left.)=163^{\circ}\right)$. This interaction should stabilise the palladium intermediates of a catalytic cycle for our cationic phosphines even more than for the SPhos derivatives. Therefore our catalytic system should outperform in catalysis, in which catalyst decomposition is an issue.

Figure 34: solid state structure of palladium complex 196 (one molecule of the two units in the unit cell shown) and the by Buchwald reported palladium complex 200. Hydrogen atoms and anions are omitted for clarity. Anisotropic displacement parameter are shown at 50\% probability level.

With these palladium complexes we then tested their applications in catalysis. We first performed the already mentioned direct arylation of thiophene reported by Itami et al. ${ }^{106}$

Figure 35: ligand effect in the phenylation of chloro thiophene 152 ( 1.5 eq ) with phenyl iodide ( 1 eq ) in m-xylene ( 0.5 M ) at $120^{\circ} \mathrm{C}$ with $1.5 \mathrm{eq} \mathrm{AgBF}_{4}$ and $5 \mathrm{~mol} \%$ of the corresponding palladium complexes. Conversion to phenyl chloro thiophene shown. Conversion were determined by GC versus an internal standard (eicosane).

While more electron poor ligand slightly promoted the reaction - triphenylphosphite instead of triphenylphosphine led to $3 \%$ conversion instead of $1 \%$ - sterically hindered and therefore kinetically more stable phosphines like SPhos 22 enhanced the reaction rate even further (7\%). Combining both effects in the pyridinium phosphines 126c led to a high conversion of $33 \%$ after 30 min . to the desired product. However, under the reaction conditions this product further reacted with prolonged reaction times to deliver the diphenylated thiophene. This wanes the reaction of limited use.

To avoid the additional phenylation we decided to design intermolecular systems, which should possess similar reactivity.

203
and

204

Scheme 80: designed intermolecular system for C-H activation with palladium.

After several optimizations we were able to prepare both system in a short and reliable synthesis. Compound 203 was obtained by Mitsunobu etherification of 2(5H)-thiophenone (205) with bromo benzyl alcohol (206) in the presence of DTAD and $\mathrm{PPh}_{3}(46 \%),{ }^{18}$ while compound 204a was prepared through Wittig reaction of 2-thiophenecarboxaldehyde (207) and the corresponding phosphonium salt (208; 88\%) followed by reduction with iodine and phosphinic acid (76\%) ${ }^{119}$.

Scheme 81: synthesis of substrates for the intermolecular C-H activation.
With these substrates in hand, we tested them in the palladium catalysis. However, none of the desired products was formed.

The first substrate 203a reacted in a Friedel-Crafts type reaction, resulting in nucleophilic substitution of the thienone fragment and formation of 2-benzyl-1,4-dimethylbenzene (210). This reaction is believed to be promoted by the high Lewis acidity of the monoligated palladium sources or the silver salt, which activates the oxygen atom of the ether bridge, to promote its nucleophilic substitution by mesitylene.

Scheme 82: reaction of substrate 203a to benzyldimethylbenzene 210.

[^46]

Scheme 83: proposed reaction mechanism for the transformation of ether 203a to arene 210.
Due to the absence of the ether bridge the second substrate should not undergo a FriedelCrafts type reaction, we hoped to transform the substrate to the desired tricyclic system 213. However, with all the different catalytic systems employed, only starting material was reisolated. This might be caused by the inefficient orbital overlap between the $\pi$-System and the bromo arene during the oxidative addition step as this occurs from within the plane, while the aromatic system points above or below the plane of the molecule.

Scheme 84: attempted C-H activation and oxidative, intermolecular coupling of thiophene 204a to tricyclic system 213.
To be able to assess whether or not the lack of reactivity of the before mentioned transformation is caused by inefficient orbital overlap or due to the slow rate of the oxidative addition step, we decided to test an palladium catalysed amination described by Buchwald et $a l$. in which the substrate is known to easily undergo the oxidative insertion elemental step.

Buchwald et al. ${ }^{120}$ reported that the SPhosPd complex 214 undergoes - after activation with a strong base generating the reactive $\mathrm{Pd}^{0}$ metal - oxidative addition even at $-40^{\circ} \mathrm{C}$ in THF with aryl chlorides generating aryl chloro palladium complex 215.

(a)
(b)

Figure 36: ${ }^{31} \mathrm{P}\{1 \mathrm{H}\}$ NMR spectra of (a) 214 in toluene $/ \mathrm{PhCl}$ at $-40^{\circ} \mathrm{C}$ and
(b) 214 in toluene/PhCl w/LHMDS (1 equiv) after 110 min at $-40^{\circ} \mathrm{C} .{ }^{120}$

We then employed our ligand system 191e as well as different phenyl halides and tested, whether or not higher conversion than the catalyst loading ( $1 \mathrm{~mol} \%$ ) could be achieved to confirm a full catalytic cycle undergoing. First, we tested phenyl chloride and morpholine at room temperature; however, no conversion was obtained even employing different bases (LiHMDS, $\mathrm{K}_{2} \mathrm{CO}_{3}$ and NaOtBu ) to achieve activation of the catalyst. Luckily, employing phenyl bromide or phenyl iodide, conversions to some extend could be achieved ( $18 \%$ for bromide and $40 \%$ for iodide within 2 h ), confirming the reactivity of the developed catalytic system, however it should be noted, that the reactivity drastically depletes, probable due to catalyst degradation processes. With these results we could confirm, that the catalytic mixture undergoes all elemental reaction steps for the palladium catalysed direct arylation including the difficult oxidative addition. Even at $-20^{\circ} \mathrm{C}$ for aryl iodides higher conversions than the catalyst loading could be achieved (up to $10 \%$ ), confirming once again several catalytic cycle undergoing.

[^47]

Scheme 85: Buchwald-Hartwig-coupling of morpholine with aryl halides
In the before mentioned reaction we applied LiHMDS as a base, which seems to be compatible to some extend with the newly developed palladium complex 196. To test whether or not the catalytic mixture is compatible with other bases or if higher conversion could be obtained with different bases employed, we then tested other sterically hindered bases for the activation process and the deprotonation of morpholine. We found, that neither $\mathrm{K}_{2} \mathrm{CO}_{3}$ nor NaOtBu are compatible with the catalytic system 196 yielding no conversion at all.

Despite the low reactivity of the applied palladium catalyst, at least to some extend the reactivity of cationic phosphines in palladium catalysed reactions could be confirmed. The newly developed palladium complexes undergo every elemental step necessary for a Pd catalysed reaction. However, due to the low stability of the developed system or the degradation processes observed further development is necessary. Furthermore, it could be shown, that these cationic palladium complexes tolerate to some extend the employment of strong, hindered bases such as LiHMDS. Further development of the employed catalytic systems is necessary to avoid catalyst decomposition and reach full conversions.

## 9. Summary and Outlook

In summary we were able to develop new cationic phosphines and successfully apply them in transitions metal catalyses. In $\pi$-acid catalysis they proved their superiority in comparison with state of the art ligand systems described in literature. The pyridinium phosphines were prepared through a concise two step sequence (methylation and phosphination) from commercially available starting materials in excellent yields. We evaluated their electronic structure by CO-stretching frequency analysis of the corresponding Vaska-type complexes and by cyclic voltammetry. Furthermore, we have examined the solid state structure of the phosphine themselves and the corresponding metal complexes through x-ray analysis.

The coordination behaviour to $\mathrm{Au}(\mathrm{I}), \mathrm{Pt}(\mathrm{II}), \mathrm{Rh}(\mathrm{I})$ and $\mathrm{Pd}(\mathrm{II})$ sources was also evaluated and the obtained complexes were applied in catalyses.

The newly developed pyridinium phosphines show tremendous effects in the described reactions. For example in hydroarylations reaction times as short as a few minutes can be achieved, while classical ligands like triphenylphosphine need several hours to achieve similar conversions. This beneficial effect was shown in two platinum, one gold and one palladium catalysed reaction.

After this promising results we then further improved the pyridinium phosphines through introduction of an aryl unit towards the nitrogen of the pyridinium moiety allowing secondary stabilizing interactions to the coordinated metal centre.

The benefits of this additional stabilisation was shown along a [2+2] cycloaddition. In comparison to the previously described methyl substituted pyridinium phosphines the aryl substituted pyridinium phosphine gave even better results. For example, the catalyst loading could be vastly reduced performing complex reaction at only $0.2 \mathrm{~mol} \%$ catalyst loading.

Overall, we could prepare new pyridinium substituted phosphines, confirm their solid state structure, assess their electronic nature, exploit their coordination chemistry and apply the corresponding complexes in catalysis with excellent results.

## 10. Experimental part

### 10.1 General procedures

All manipulations were carried out under argon atmosphere either in flame-dried glassware on a Schlenk line or in an MBraun Labmaster 130 Glove box, unless stated otherwise. The solvents employed for the reactions were purified by distillation over the drying agents indicated and were stored and handled under argon atmosphere: THF, $\mathrm{Et}_{2} \mathrm{O}$ ( $\mathrm{Mg} /$ anthracene ), $\mathrm{CH}_{2} \mathrm{Cl}_{2}, \mathrm{CHCl}_{3}$, fluorobenzene, chlorobenzene, 1,2-dichlorobenzene, pyridine, $\mathrm{NEt}_{3}\left(\mathrm{CaH}_{2}\right.$, stored over $4^{\circ} \mathrm{A}$ molecular sieves), n-pentane, toluene $(\mathrm{Na} / \mathrm{K})$, MeOH ( Mg , stored over $3 \AA$ molecular sieves). DMF, 1,4-dioxane and $\mathrm{CH}_{3} \mathrm{CN}$ were dried by an adsorption solvent purification system based on molecular sieves. Benzene was dried by treatment of a freshly opened bottle with activated $4^{\circ} \mathrm{A}$ molecular sieves and then stored under inert atmosphere. Flash chromatography separations were performed using Merck 60 silica gel ( $40-63 \mu \mathrm{~m}$ ), whereas preparative thin-layer chromatography (TLC) was performed on Merck 25-DC-Plastic sheets ( $20 \times 20 \mathrm{~cm}$ ) coated with 60 silica gel. Reactions were controlled by TLC analysis, performed using Merck silica gel 60 F254 TLC plates and visualised by UV irradiation and/or ceric ammonium molybdate or potassium permanganate dip. When it was possible, the reactions were additionally followed by GC/MS measurements performed on Agilent Technology GC 6890 Series and MSD 5973 (carrier gas: helium) with HP6890 Series Injector, employing a MN 121 III. 1.
All commercially available compounds (Acros, Fluka, Lancaster, Alfa Aesar and Aldrich) were used as received unless stated otherwise. Compounds $\mathbf{1 3 4}{ }^{113}, \mathbf{1 3 8}^{121}, \mathbf{1 4 0}{ }^{104}$ and $\mathbf{2 2 0}{ }^{117}$ were prepared accordingly to the procedure described in the literature

### 10.2 Experimental procedures and characterizations

NMR spectra were recorded on a Bruker AV500, AV400 or DPX300 as stated for each case, using dry deuterated solvents. ${ }^{1} \mathrm{H}$ and ${ }^{13} \mathrm{C}$ chemical shifts are given in ppm relative to TMS, using the solvent signals as references and converting the chemical shifts to the TMS scale. ${ }^{31} \mathrm{P}$ and ${ }^{19} \mathrm{~F}$ chemical shifts are given in ppm relative to $\mathrm{H}_{3} \mathrm{PO}_{4}$ and $\mathrm{CFCl}_{3}$ respectively (external standard). Mass spectrometry analysis was performed by the department for mass spectrometry at the Max-Planck-Institut für Kohlenforschung, using the following equipment: Finnigan MAT 8200 ( 70 eV , EI), Finnigan MAT 95 (ESI) and Bruker APEX III FT-MS (7 T magnet, HRMS). Infrared spectra were recorded on Nicolet FT-7199 or Bruker ALPHA FT-IR Platinum ATR spectrometers at room temperature. X-Ray diffraction analysis was performed by the department of chemical at the Max-Planck-Institut für Kohlenforschung. The X-ray

[^48]intensity data were measured on a Bruker AXS Proteum X8, Bruker AXS KappaCCD and Bruker AXS Apex II diffractometers. The crystal structures were solved by direct methods using SHELXS-97 and refined with SHELXL-2014. The crystals suitable for X-ray analysis were grown by slow diffusion of different solvent mixtures of the metal complexes or by slow solvent evaporation/cooling of saturated solutions of the corresponding compounds.

## General procedure for the Alkylation of 2-Chloropyridines.

A solution of the corresponding 2-chloropyridine (1 equiv.) in DCM ( 0.05 M ) was added to solid $\mathrm{Me}_{3} \mathrm{OBF}_{4}$ or $\mathrm{Et}_{3} \mathrm{OBF}_{4}$ (1 equiv.) and the suspension stirred overnight. Then, the solvent was filtered off and the remaining white solid washed twice with dichloromethane and dried in vacuum.

Compound 127a: Prepared from 2-chloropyridine ( $2.0 \mathrm{~g}, 17.6 \mathrm{mmol}$ ) and

$\mathrm{Me}_{3} \mathrm{OBF}_{4}(2.6 \mathrm{~g}, 17.6 \mathrm{mmol})$ following the general procedure. After washing with DCM ( $2 \times 20 \mathrm{ml}$ ), 127a was obtained as a white solid ( $3.47 \mathrm{~g}, 91 \%$ ).
${ }^{1} \mathrm{H}$ NMR $\left(300 \mathrm{MHz}, \mathrm{CD}_{3} \mathrm{CN}\right) \delta=8.75(\mathrm{~d}, J=6.2 \mathrm{~Hz}, 1 \mathrm{H}), 8.47(\mathrm{td}, J=8.2,1.5 \mathrm{~Hz}$, $1 \mathrm{H}), 8.12(\mathrm{~d}, \mathrm{~J}=8.3 \mathrm{~Hz}, 1 \mathrm{H}), 7.94\left(\mathrm{t},{ }^{3} \mathrm{~J}=6.8 \mathrm{~Hz}, 1 \mathrm{H}\right), 4.30(\mathrm{~s}, 3 \mathrm{H}) ;{ }^{13} \mathrm{C}$ NMR ( $75 \mathrm{MHz}, \mathrm{CD}_{3} \mathrm{CN}$ ) $\delta=149.0,148.9,148.4,131.0,127.4,48.6$; IR (neat) $\bar{v}=712,735,778,805,1024,1123$, 1177, 1274, 1286, 1314, 1446, 1499, 1574, 1623, 3059, 3094, 3115, $3138 \mathrm{~cm}^{-1}$ HRMS calcd. for $\mathrm{C}_{12} \mathrm{H}_{14} \mathrm{BCl}_{2} \mathrm{~F}_{4} \mathrm{~N}_{2}$ : 343.056684; found: 343.056646 .

Compound 127b: Prepared from 2-chloro-5-fluoropyridine ( $1.0 \mathrm{~g}, 7.6 \mathrm{mmol}$ ) and $\mathrm{Me}_{3} \mathrm{OBF}_{4}(1.12 \mathrm{~g}, 7.6 \mathrm{mmol})$ following the general procedure. After washing with DCM ( $2 \times 20 \mathrm{ml}$ ), 127b was obtained as a white solid ( $1.75 \mathrm{~g}, 99 \%$ ).
${ }^{1} \mathrm{H}$ NMR $\left(300 \mathrm{MHz}, \mathrm{CD}_{3} \mathrm{CN}\right) \delta=8.88(\mathrm{t}, J=3.1 \mathrm{~Hz}, 1 \mathrm{H}), 8.36$ (ddd, $J=9.4,6.7$, $2.9 \mathrm{~Hz}, 1 \mathrm{H}), 8.16$ (dd, $J=9.3,4.9 \mathrm{~Hz}, 1 \mathrm{H}), 4.31(\mathrm{~s}, 3 \mathrm{H}) ;{ }^{13} \mathrm{C}$ NMR ( $75 \mathrm{MHz}, \mathrm{CD}_{3} \mathrm{CN}$ ) $\delta=159.9$ ( $\mathrm{d}, J_{C-F}=255.1 \mathrm{~Hz}$ ), 145.6, $138.7\left(\mathrm{~d}, J_{C-F}=40.0 \mathrm{~Hz}\right), 136.2\left(\mathrm{~d}, J_{C-F}=19.8 \mathrm{~Hz}\right), 132.2\left(\mathrm{~d}, J_{C-F}=\right.$ 7.9 Hz ), 49.5; ${ }^{19} \mathrm{~F}$ NMR ( $282 \mathrm{MHz}, \mathrm{CD}_{3} \mathrm{CN}$ ) $\delta=-120.22,-151.77,-151.82$; IR (neat) $\bar{v}=655$, 698, 743, 767, 854, 901, 1022, 1126, 1165, 1282, 1392, 1439, 1509, 1593, 1641, 3084, 3104 $\mathrm{cm}^{-1}$; HRMS calcd. for $\mathrm{C}_{12} \mathrm{H}_{12} \mathrm{~N}_{2} \mathrm{BCl}_{2} \mathrm{~F}_{6}$ : 379.036928; found: 379.037035.

Compound 127c: Prepared from 2-chloro-5-(trifluoromethyl)pyridine (400 $\mathrm{mg}, 2.2 \mathrm{mmol}$ ) and $\mathrm{Me}_{3} \mathrm{OBF}_{4}$ ( $325 \mathrm{mg}, 2.2 \mathrm{mmol}$ ) following the general procedure. After washing with DCM ( $2 \times 2 \mathrm{ml}$ ), 127c was obtained as a white solid ( $620 \mathrm{mg}, 99 \%$ ).
${ }^{1} \mathrm{H}$ NMR ( $300 \mathrm{MHz}, \mathrm{CD}_{3} \mathrm{CN}$ ) $\delta=9.23(\mathrm{~s}, 1 \mathrm{H}), 8.75(\mathrm{dd}, J=8.7,2.0 \mathrm{~Hz}, 1 \mathrm{H}), 8.34(\mathrm{~d}, J=8.7$ $\mathrm{Hz}, 1 \mathrm{H}), 4.39(\mathrm{~s}, 3 \mathrm{H}) ;{ }^{13} \mathrm{C}$ NMR ( $75 \mathrm{MHz}, \mathrm{CD}_{3} \mathrm{CN}$ ) $\delta=153.3,147.4(\mathrm{~m}), 145.0\left(\mathrm{q}, \mathrm{J}_{\mathrm{C}-\mathrm{F}}=3.0\right.$ $\mathrm{Hz}), 132.1,129.4\left(\mathrm{q}, J_{C-F}=37.0 \mathrm{~Hz}\right), 122.3\left(\mathrm{q}, J_{C-F}=272.7 \mathrm{~Hz}\right), 49.5 ;{ }^{19} \mathrm{~F}$ NMR ( 282 MHz , $\mathrm{CD}_{3} \mathrm{CN}$ ) $\delta=-63.45,-151.99,-152.04$; $\operatorname{IR}$ (neat) $\bar{v}=663,690,722,804,861,888,916,944$, $998,1025,1125,1192,1268,1331,1435,1479,1590,1639,2296,2342,2383,3055 \mathrm{~cm}^{-1}$; HRMS calcd. for $\mathrm{C}_{7} \mathrm{H}_{6} \mathrm{NCIF}_{3}$ : 196.013540; found: 196.013563.

Compound 127d: Prepared from 2-chloro-5-methoxypyridine ( 965 mg , 6.72 mmol ) and $\mathrm{Me}_{3} \mathrm{OBF}_{4}(994 \mathrm{mg}, 6.72 \mathrm{mmol})$ in DCM ( 20 ml ) following the general procedure. After washing with DCM ( $2 \times 20 \mathrm{ml}$ ), 127d was obtained as a white solid ( $1.47 \mathrm{~g}, 89 \%$ ).
${ }^{1} \mathrm{H}$ NMR ( $300 \mathrm{MHz}, \mathrm{CD}_{3} \mathrm{CN}$ ) $\delta=8.47(\mathrm{~d}, ~ J=2.7 \mathrm{~Hz}, 1 \mathrm{H}), 8.10-7.93(\mathrm{~m}, 2 \mathrm{H}), 4.27(\mathrm{~s}, 3 \mathrm{H})$, 4.00 (s, 3H); ${ }^{13} \mathrm{C}$ NMR ( $75 \mathrm{MHz}, \mathrm{CD}_{3} \mathrm{CN}$ ) $\delta=158.3,140.0,136.0,134.1,130.9,58.8,49.0 ;{ }^{19} \mathrm{~F}$ NMR (282 MHz, CD ${ }_{3} \mathrm{CN}$ ) $\delta=-151.67,-151.72$; IR (neat) $\bar{v}=697,739,847,875,936,1013$, 1037, 1099, 1159, 1177, 1197, 1271, 1308, 1391, 1425, 1445, 1469, 1513, 1590, 1622, 3101, $3156 \mathrm{~cm}^{-1}$; HRMS calcd. for $\mathrm{C}_{14} \mathrm{H}_{18} \mathrm{~N}_{2} \mathrm{BCl}_{2} \mathrm{~F}_{4} \mathrm{O}_{2}$ : 403.077864; found: 403.078070.

Compound 129a: Prepared from 2-chloro-5-(trifluoromethyl)pyridine ( 1 g , $5.5 \mathrm{mmol})$ and $\mathrm{Et}_{3} \mathrm{OBF}_{4}(1.05 \mathrm{~g}, 5.5 \mathrm{mmol})$ in DCM ( 20 ml ) following the general procedure and purified by filtration and washing with DCM ( 2 x 10 ml ) to afford 129a as a white solid ( $1.6 \mathrm{~g}, 5.4 \mathrm{mmol}, 99 \%$ ).
${ }^{1} \mathrm{H}$ NMR ( $300 \mathrm{MHz}, \mathrm{CD}_{3} \mathrm{CN}$ ) $\delta=9.24(\mathrm{~d}, J=0.7 \mathrm{~Hz}, 1 \mathrm{H}), 8.74$ (dd, $\left.J=8.7,2.1 \mathrm{~Hz}, 1 \mathrm{H}\right), 8.34$ (d, $J=8.7 \mathrm{~Hz}, 1 \mathrm{H}$ ), $4.82(\mathrm{q}, ~ J=7.3 \mathrm{~Hz}, 2 \mathrm{H}), 1.62(\mathrm{t}, J=7.3 \mathrm{~Hz}, 3 \mathrm{H}) ;{ }^{13} \mathrm{C}$ NMR ( $75 \mathrm{MHz}, \mathrm{CD}_{3} \mathrm{CN}$ ) $=152.3,146.3,144.9\left(q, J_{C-F}=3.0 \mathrm{~Hz}\right), 132.8,129.9\left(\mathrm{q}, J_{C-F}=36.9 \mathrm{~Hz}\right), 122.2\left(\mathrm{q}, J_{C-F}=273.7\right.$ Hz ); ${ }^{19} \mathrm{~F}$ NMR ( $282 \mathrm{MHz}, \mathrm{CD}_{3} \mathrm{CN}$ ) $\delta=-63.46,-151.88,-151.94$; IR (neat) $\bar{v}=727,740,767$, 809, 858, 939, 1023, 1056, 1095, 1110, 1146, 1183, 1193, 1233, 1299, 1328, 1395, 1413, 1453, 1473, 1509, 1586, 1639, $3089 \mathrm{~cm}^{-1}$; HRMS calcd. for $\mathrm{C}_{8} \mathrm{H}_{8} \mathrm{NCIF}_{3}$ : 210.029185; found: 210.028857.

Compound 129b: Prepared from 2-chloro-5-nitropyridine ( 500 mg , 3.15 mmol ) and $\mathrm{Me}_{3} \mathrm{OBF}_{4}(466 \mathrm{mg}, 3.15 \mathrm{mmol})$ in DCM ( 20 ml ) following the general procedure. After washing with DCM ( $2 \times 20 \mathrm{ml}$ ), 129b was obtained as a white solid ( $855 \mathrm{mg}, 99 \%$ ).

## General procedure for the Chlorination of 2-Pyridones 131

To a solution of 131 ( 1 eq ) in dichloroethane ( $10 \mathrm{ml} / \mathrm{mmol}$ ) was added oxalylchlorid (3 eq) and dimethylformamid ( 0.1 ml ). The resulting mixture was heated overnight to $80^{\circ} \mathrm{C}$. After cooling to rt the reaction mixture was quenched with $\mathrm{H}_{2} \mathrm{O}$ and diluted with ethylacetate. After addition of sat. aq. $\mathrm{NaBF}_{4}$ solution, the aqueous phase was extracted with dichloromethane ( $3 \times 50 \mathrm{ml}$ ). The combined organic phases were dried over MgSO4, filtered and concentrated. The solid obtained was washed with a small amount of THF ( $1 \mathrm{ml} / \mathrm{mmol}$ ) or crystallized from DCM/nPentane if necessary and dried in vacuum.

$\mathrm{BF}_{4}$
Compound 132a: Prepared from 131a ( $500 \mathrm{mg}, 3.3 \mathrm{mmol}$ ), oxalylchlorid ( 0.85 $\mathrm{ml}, 10 \mathrm{mmol}$ ) and dimethylformamid ( 0.1 ml ) in dichloroethane following the general procedure. Brownish solid ( $660 \mathrm{mg}, 78 \%$ ).

## General procedure for the Preparation of Pyridiniophosphines.

To a solution of the corresponding 1-alkyl/aryl-2-chloropyridinium tetrafluoroborate (1 equiv.) in THF ( 2 ml ) was added the desired secondary phosphine (2.5-3.0 equiv.) and the resulting suspension heated for 1 to 3 days. After cooling to rt, the solvents were evaporated and the crude reaction mixture washed with $n$-Pentan $(2 \times 2 \mathrm{ml})$, solved in DCM and washed with sat. $\mathrm{NaBF}_{4}$ aqueous solution. The organic phase was dried over $\mathrm{NaSO}_{4}$ and the solvent evaporated. If necessary, the resulting solid could be further purified by an additional wash with THF (1-2 mI).

Compound 124a: Prepared by heating a THF suspension of 127 ( 400 mg , $1.8 \mathrm{mmol})$ and diphenylphosphine ( $1.1 \mathrm{ml}, 5.6 \mathrm{mmol}$ ) at $65^{\circ} \mathrm{C}$ for 3 days. White solid ( $477 \mathrm{mg}, 70 \%$ ).

## General procedure for the preparation of pyridiniophosphine rhodium complexes.

$\left[\mathrm{Rh}(\mathrm{CO})_{2} \mathrm{Cl}\right]_{2}$ ( 0.25 equiv.) was added to a solution of the corresponding pyridiniophosphine ligand (1 equiv.) in DCM ( 2 ml ). The resulting suspension was stirred for 1 hour at rt and after evaporation of the solvent, the solid was washed with $n$-pentan ( $2 \times 2 \mathrm{ml}$ ) and dried in vacuum. These compounds can be crystalized from acetonitrile/ether mixtures.

Compound 135a: Prepared from 127a ( $100 \mathrm{mg}, 0.274 \mathrm{mmol}$ ) and $\left[\mathrm{Rh}(\mathrm{CO}) \mathrm{Cl}_{2}\right]_{2}(26.6 \mathrm{mg}, 0.063 \mathrm{mmol})$ following the general procedure. Yellow solid ( $121 \mathrm{mg}, 99 \%$ ).
${ }^{1} \mathrm{H}$ NMR ( $300 \mathrm{MHz}, \mathrm{CDCN}$ ) $\delta=8.84(\mathrm{~d}, J=5.9 \mathrm{~Hz}, 2 \mathrm{H}), 8.38(\mathrm{t}, J=7.7$ $\mathrm{Hz}, 2 \mathrm{H}$ ), $8.11-8.02$ (m, 2H), 7.84 (s, 8H), $7.79-7.72$ (m, 4H), $7.72-$ $7.58(\mathrm{~m}, 10 \mathrm{H}), 4.50(\mathrm{~s}, 6 \mathrm{H}) ;{ }^{13} \mathrm{C}$ NMR ( $75 \mathrm{MHz}, \mathrm{CDCN}$ ) $\delta=186.1$ (dt, $J_{C-R h}=31.9 \mathrm{~Hz}, J_{C-P}=$ $15.6 \mathrm{~Hz}), 153.6$ ( $\mathrm{t}, \mathrm{J}_{\mathrm{C}-\mathrm{P}}=18.1 \mathrm{~Hz}$ ), 151.1, 145.6, 136.2, 135.0, 134.2, 131.1, 130.1, 126.6 ( t , $\left.J_{C-P}=24.3 \mathrm{~Hz}\right), 50.8 ;{ }^{31} \mathrm{P}$ NMR ( $121 \mathrm{MHz}, \mathrm{CDCN}$ ) $\delta=37.82\left(\mathrm{~d}, J_{P-R h}=130.7 \mathrm{~Hz}\right.$ ); IR (neat) $\bar{v}$ $=692,707,752,773,799,900,931,998,1056,1165,1182,1274,1314,1411,1438,1481$, 1499, 1576, 1610, 1996, 3093, $3138 \mathrm{~cm}^{-1}$; HRMS calcd. for $\mathrm{C}_{37} \mathrm{H}_{34} \mathrm{BCIF}_{4} \mathrm{~N}_{2} \mathrm{OP}_{2} \mathrm{Rh}^{2}$ 809.092884; found: 809.093025.

## General procedure for the preparation of the phosphine platinum complexes.

Finely grounded $\mathrm{K}_{2} \mathrm{PtCl}_{4}$ (1 equiv) was added to a solution of the pyridiniophosphine salt ( 1 equiv.) in MeCN ( 2 ml ) and the resulting suspension stirred overnight at rt . After evaporation of the solvent, the solid was washed with $n$-Pentan ( $2 \times 2 \mathrm{ml}$ ), crystallized from DMSO/DCM and dried in vacuum to yield the desired platinum complexes.

Compound 136a: Prepared from 124a ( $100 \mathrm{mg}, 0.274 \mathrm{mmol}$ ) and $\mathrm{K}_{2} \mathrm{PtCl}_{4}$ ( $114 \mathrm{mg}, 0.274 \mathrm{mmol}$ ) following the general procedure. White solid ( 127 mg , 80\%).
${ }^{1} \mathrm{H}$ NMR ( $\left.300 \mathrm{MHz}, \mathrm{DMSO}\right) \delta=9.18(\mathrm{~d}, J=5.7 \mathrm{~Hz}, 1 \mathrm{H}), 8.53(\mathrm{t}, J=7.9 \mathrm{~Hz}, 1 \mathrm{H}), 8.20(\mathrm{t}, J=$ $6.9 \mathrm{~Hz}, 1 \mathrm{H}), 8.02(\mathrm{dd}, J=12.3 \mathrm{~Hz}, J=7.2 \mathrm{~Hz}, 4 \mathrm{H}), 7.79-7.57(\mathrm{~m}, 6 \mathrm{H}), 7.39(\mathrm{t}, J=7.0 \mathrm{~Hz}$, $1 \mathrm{H}), 4.35(\mathrm{~s}, 3 \mathrm{H}) ;{ }^{13} \mathrm{C}$ NMR $\left(75 \mathrm{MHz}, \mathrm{CD}_{3} \mathrm{CN}\right) \delta=150.1,144.5\left(\mathrm{~d}, J_{C-P}=5.7 \mathrm{~Hz}\right), 135.3\left(\mathrm{~d}, J_{C-}\right.$ $p=11.6 \mathrm{~Hz}), 132.8\left(\mathrm{~d}, J_{C-p}=7.5 \mathrm{~Hz}\right), 132.6\left(\mathrm{~d}, J_{C-P}=2.5 \mathrm{~Hz}\right), 129.3\left(\mathrm{~d}, J_{C-p}=11.6 \mathrm{~Hz}\right), 128.8$, 124.6, 123.7, $48.3\left(\mathrm{~d}, J_{C-P}=7.3 \mathrm{~Hz}\right) ;{ }^{31} \mathrm{P}$ NMR ( $\left.121 \mathrm{MHz}, \mathrm{DMSO}\right) \delta=8.49(J=3908 \mathrm{~Hz})$; IR (neat) $\bar{v}=673,822,1003,1023,1051,1659,2126,2253,2342,2383 \mathrm{~cm}^{-1} ;$ HRMS for DMSO adduct calcd. for $\mathrm{C}_{20} \mathrm{H}_{23} \mathrm{Cl}_{2} \mathrm{NOPPtS}$ : 621.024487; found: 621.024734.

#### Abstract

Compound 136b: Prepared from 124c ( $100 \mathrm{mg}, 0.231 \mathrm{mmol}$ ) and $\mathrm{K}_{2} \mathrm{PtCl}_{4}(96 \mathrm{mg}, 0.231 \mathrm{mmol})$ following the general procedure. ## General procedure for the synthesis of $\mathbf{R h}(\mathrm{cod})$ complexes.

$[\mathrm{RhCl}(\operatorname{cod})]_{2}(0.5$ equiv.) was added to a solution of the corresponding pyridiniophosphine ligand (1 equiv.) in DCM ( 2 ml ). The resulting suspension was stirred for 1 hour at rt and after evaporation of the solvent, the solid was washed with $n$-pentane ( $2 \times 2 \mathrm{ml}$ ) and dried in vacuum.

## General procedure for the synthesis of palladium complexes.

$(\mathrm{MeCN}){ }_{2} \mathrm{PdCl}_{2}$ ( 0.5 equiv.) was added to a solution of the corresponding pyridiniophosphine ligand (1 equiv.) in DCM ( 2 ml ). The resulting suspension was stirred for 1 hour at rt and after evaporation of the solvent, the solid was washed with $n$-pentane ( $2 \times 2 \mathrm{ml}$ ) and dried in vacuum. These compounds can be crystalized from acetonitrile/ether mixtures.

Compound 151a: Prepared from 124a ( $100 \mathrm{mg}, 0.27 \mathrm{mmol}$ ) and $(\mathrm{MeCN})_{2} \mathrm{PdCl}_{2}(35.5 \mathrm{mg}, 0.14 \mathrm{mmol})$ following the general procedure. Yellow solid ( $123 \mathrm{mg}, 74 \%$ ).

General scheme for the synthesis of pyridinium phosphines 190

## General procedure for the synthesis pyridinium tetrafluoroborates 176

To a solution of 175 ( 1 eq ) in $n$-Butanol ( $3 \mathrm{ml} / \mathrm{mmol}$ ) was added the corresponding amine ( 1 eq). The resulting mixture was stirred for 3 days at $125^{\circ} \mathrm{C}$. After cooling to rt the solvent was evaporated and $\mathrm{H}_{2} \mathrm{O}$ ( 100 ml ) was added to the crude reaction mixture. After filtration the aqueous solution was washed with dichloromethane ( $3 \times 50 \mathrm{ml}$ ), then $\mathrm{NaBF}_{4}$ was added to the aqueous phase and the solution extracted with dichloromethane ( $3 \times 100 \mathrm{ml}$ ). The combined
organic phases were dried over $\mathrm{MgSO}_{4}$, filtered and concentrated. The solid thus obtained was dried in vacuum.

Compound 176a: Prepared from 175 ( $900 \mathrm{mg}, 3.2 \mathrm{mmol}$ ) and mesitylamine ( $0.45 \mathrm{ml}, 3.2 \mathrm{mmol}$ ) following the general procedure. White solid ( $545 \mathrm{mg}, 73 \%$ ).
${ }^{1} \mathrm{H}$ NMR $\left(400 \mathrm{MHz}, \mathrm{CDCl}_{3}\right) \delta=8.76(\mathrm{tt}, J=8.0,1.3 \mathrm{~Hz}, 1 \mathrm{H}), 8.66$ (dd, $J=$ $6.7,1.3 \mathrm{~Hz}, 2 \mathrm{H}$ ), 8.40 (dd, $J=7.8,6.7 \mathrm{~Hz}, 2 \mathrm{H}$ ), 7.06 (s, 2H), 2.36 (s, 3H), 1.95 (s, 6H); ${ }^{13} \mathrm{C}$ NMR ( $100 \mathrm{MHz}, \mathrm{CDCl}_{3}$ ) $\delta=147.4,145.9,142.0,139.3,132.4,130.3,130.0$, 21.2, 17.1; IR (neat) $\bar{v}=434,458,520,554,576,690,713,733,784,852,955,1026,1046$, 1208, 1237, 1268, 1286, 1392, 1471, 1627, $3075,3129 \mathrm{~cm}^{-1}$; HRMS calcd. for $\mathrm{C}_{14} \mathrm{H}_{16} \mathrm{~N}$ : 198.127724; found: 198.127690.

## General procedure for the synthesis of chloropyridinium tetrafluoroborates 189:

To a solution of $188(1 \mathrm{eq})$ in dichloroethane ( $10 \mathrm{ml} / \mathrm{mmol}$ ) was added oxalylchlorid (3 eq) and dimethylformamid ( 0.1 ml ). The resulting mixture was heated overnight to $80^{\circ} \mathrm{C}$. After cooling to it the reaction mixture was quenched with $\mathrm{H}_{2} \mathrm{O}$ and diluted with ethylacetate. After addition of sat. aq. $\mathrm{NaBF}_{4}$ solution, the aqueous phase was extracted with dichloromethane ( $3 \times 50 \mathrm{ml}$ ). The combined organic phases were dried over $\mathrm{MgSO}_{4}$, filtered and concentrated. The solid obtained was washed with a small amount of THF ( $1 \mathrm{ml} / \mathrm{mmol}$ ) or crystallized from DCM/n-pentane and dried in vacuum.

Compound 189a: Prepared from 188a ( $229 \mathrm{mg}, 1.0 \mathrm{mmol}$ ), oxalylchlorid ( $0.26 \mathrm{ml}, 3.0 \mathrm{mmol}$ ) and dimethylformamid ( 0.1 ml ) in dichloroethane following the general procedure. Brownish solid ( $181 \mathrm{mg}, 57 \%$ ).
${ }^{1} \mathrm{H}$ NMR $\left(400 \mathrm{MHz}, \mathrm{CDCl}_{3}\right) \delta=8.90(\mathrm{td}, J=7.9,1.3 \mathrm{~Hz}, 1 \mathrm{H}), 8.79(\mathrm{dd}, J=$ $6.1,1.7 \mathrm{~Hz}, 1 \mathrm{H}), 8.49-8.42(\mathrm{~m}, 1 \mathrm{H}), 8.41-8.34(\mathrm{~m}, 1 \mathrm{H}), 7.11(\mathrm{~s}, 2 \mathrm{H})$, 2.39 (s, 3H), $1.96(\mathrm{~s}, 6 \mathrm{H}) ;{ }^{13} \mathrm{C} \operatorname{NMR}\left(101 \mathrm{MHz}, \mathrm{CDCl}_{3}\right) \delta=150.3,148.8,147.4,142.8,137.4$, 132.6, 130.7, 130.6, 129.2, 21.3, 17.3; IR (neat) $\bar{v}=427,451,479,517,550,572,587,636$, 691, 726, 749, 763, 783, 822, 860, 914, 1029, 1056, 1100, 1134, 1224, 1258, 1348, 1378, 1439, 1472, 1565, 1612, 1672, 1897, 2927, 2979, 3058, $3119 \mathrm{~cm}^{-1}$; HRMS calcd. for $\mathrm{C}_{14} \mathrm{H}_{15} \mathrm{NCl}$ : 232.088752 ; found: 232.088680 .

## General Procedure for the synthesis of pyridiniumphosphine salts 190:

## Method A:

The corresponding phosphine (3 equiv.) was added to a solution of 189 (1 equiv.) in THF (3 $\mathrm{ml} / \mathrm{mmol}$ ) inside a microwave. The resulting mixture was heated to $120-140^{\circ} \mathrm{C}$ for 12 h . After evaporation of the solvent the residue was washed with $n$-pentane ( $2 \times 5 \mathrm{ml}$ ), redissolved in acetonitrile and then $\mathrm{NaSbF}_{6}$ (3 equiv) was added. After evaporation of the solvents dichloromethane was added and filtered. Evaporation of the solvents and recrystallization from dichlormethane/ $n$-pentan gave the desired compounds.

Method B:
A suspension of potassium hydride ( 8 equiv.) in THF ( $3 \mathrm{ml} / \mathrm{mmol}$ ) was cooled to $-78^{\circ} \mathrm{C}$ and then the desired phosphine (1 equiv) was added. The resulting mixture was stirring for 1 h , letting it warm up to $-50^{\circ} \mathrm{C}$. The excess of potassium hydrid was filtered off and the resulting solution was transferred at $-78^{\circ} \mathrm{C}$ to a precooled solution $\left(-78^{\circ} \mathrm{C}\right)$ of the chloropyridinium salt 189 in THF ( $3 \mathrm{ml} / \mathrm{mmol}$ ). The resulting mixture was stirred overnight, while it was allowed to warm up to rt. After evaporation of the solvent the residue was washed with $n$-pentane ( 2 x 5 ml ), redissolved in acetonitrile and $\mathrm{NaSbF}_{6}$ ( 3 eq ) was added. The obtained mixture was stirred for 3 h and after evaporation of solvents, DCM was added and the resulting salts filtered off. Evaporation of the filtrate and recrystallization from dichlormethane/n-pentane gave the desired compound.

Compound 190a: Prepared from potassium hydride ( $474 \mathrm{mg}, 11.8 \mathrm{mmol}$ ), bis(3,5-
 bis(trifluoromethyl)phenyl)phosphine ( $678 \mathrm{mg}, 1.48 \mathrm{mmol}$ ), 189b ( $500 \mathrm{mg}, 1.48 \mathrm{mmol}$ ), and $\mathrm{NaSbF}_{6}(1150 \mathrm{mg}, 4.45 \mathrm{mmol})$ following the general procedure. ## General Procedure for the synthesis of pyridiniumphosphin gold complexes 191:

$\mathrm{Me}_{2} \mathrm{~S} \cdot \mathrm{AuCl}$ (1 equiv.) was added to the phosphine 190 (1 equiv.) in $\mathrm{DCM}(1 \mathrm{ml} / \mathrm{mmol}$ ) at rt . After stirring for 1 h the solvent was evaporated and the resulting solid washed with $\mathrm{Et}_{2} \mathrm{O}(2 \mathrm{x}$ $2 \mathrm{ml} / \mathrm{mmol}$ ) and $n$-pentane ( $2 \times 2 \mathrm{ml} / \mathrm{mmol}$ ).

Compound 191a: Prepared from phosphine 190a ( $100 \mathrm{mg}, 0.11$ mmol ) and $\mathrm{Me}_{2} \mathrm{~S} \cdot \mathrm{AuCl}(32.4 \mathrm{mg}, 0.11 \mathrm{mmol})$ following the general procedure. White solid ( $111.6 \mathrm{mg}, 89 \%$ ).
${ }^{1} \mathrm{H}$ NMR ( $400 \mathrm{MHz}, \mathrm{CD}_{3} \mathrm{CN}$ ) $\delta=8.80$ (ddd, $J=6.1,3.3,1.4 \mathrm{~Hz}$, $1 \mathrm{H}), 8.75(\mathrm{tt}, J=8.1,1.5 \mathrm{~Hz}, 1 \mathrm{H}), 8.40(\mathrm{~s}, 3 \mathrm{H}), 8.14(\mathrm{~d}, J=13.5$ $\mathrm{Hz}, 4 \mathrm{H}), 8.06(\mathrm{t}, J=7.3 \mathrm{~Hz}, 1 \mathrm{H}), 7.65(\mathrm{t}, J=8.6 \mathrm{~Hz}, 1 \mathrm{H}), 6.67$ (d, $J=8.6 \mathrm{~Hz}, 2 \mathrm{H}), 3.50(\mathrm{~s}, 6 \mathrm{H}) ;{ }^{13} \mathrm{C} \operatorname{NMR}\left(101 \mathrm{MHz}, \mathrm{CD}_{3} \mathrm{CN}\right) \delta=155.2,154.5,149.6(\mathrm{~d}, J=$ $5.5 \mathrm{~Hz}), 137.6(\mathrm{~d}, J=9.1 \mathrm{~Hz}), 136.9(\mathrm{~d}, J=2.7 \mathrm{~Hz}), 136.7(\mathrm{~d}, J=2.7 \mathrm{~Hz}), 136.3,133.6(\mathrm{qd}, J$ $=34.4,13.1 \mathrm{~Hz}$ ), 132.8, 129.3, $127.3(\mathrm{~d}, J=62.4 \mathrm{~Hz}), 125.0(\mathrm{q}, J=272.2 \mathrm{~Hz}), 118.8(\mathrm{~d}, J=$ 4.8 Hz ), 106.4, 57.2; ${ }^{31} \mathrm{P}$ NMR ( $162 \mathrm{MHz}, \mathrm{CD}_{3} \mathrm{CN}$ ) $\delta=30.90$; IR (neat) $\bar{v}=421,439,455,467$, $515,525,542,563,599,616,651,658,672,681,695,706,731,778,825,848,898,911,935$,

## General Procedure for the synthesis of phosphine palladium complexes 196-197:

THF ( $2 \mathrm{ml} / \mathrm{mmol}$ ) was added to a mixture of the carefully dried phosphine (1 equiv.), $\mathrm{NaSbF}_{6}$ (3 equiv.) and the palladium precursor [1,1'-biphenyl]-2-amine-palladium-mesylate-dimer (220, 0.5 equiv. $)^{117}$ at $-20^{\circ} \mathrm{C}$. After stirring for 2 hours the solvent was removed at $-20^{\circ} \mathrm{C}$ in vacuo. DCM was added and the solution obtained filtered at $-20^{\circ} \mathrm{C}$. Removal of the solvent in vacuo at $-20^{\circ} \mathrm{C}$ afforded the desired product.

Compound 196: Prepared from phosphine 191e ( $100 \mathrm{mg}, 0.154$ mmol ) and palladium precursor $220{ }^{117}(57 \mathrm{mg}, 0.077 \mathrm{mmol})$ following the general procedure. White solid ( $96.5 \mathrm{mg}, 54 \%$ ).
${ }^{1} \mathrm{H}$ NMR ( $400 \mathrm{MHz}, \mathrm{CD}_{2} \mathrm{Cl}_{2}$ ) $\delta=8.84$ (dd, $\left.J=11.3,4.1 \mathrm{~Hz}, 1 \mathrm{H}\right), 8.54$ (d, $J=7.9 \mathrm{~Hz}, 1 \mathrm{H}), 8.41(\mathrm{t}, J=8.5 \mathrm{~Hz}, 1 \mathrm{H}), 8.35-8.27(\mathrm{~m}, 2 \mathrm{H}), 7.60$ (dd, $J=7.0,2.1 \mathrm{~Hz}, 1 \mathrm{H}), 7.40-7.27(\mathrm{~m}, 5 \mathrm{H}), 7.15$ (dd, $J=11.2,7.8$ $\mathrm{Hz}, 2 \mathrm{H}), 7.06(\mathrm{~d}, \mathrm{~J}=8.4 \mathrm{~Hz}, 1 \mathrm{H}), 7.01(\mathrm{dd}, J=7.7,4.0 \mathrm{~Hz}, 1 \mathrm{H}), 5.17$ (dd, $J=10.2,4.6 \mathrm{~Hz}, 1 \mathrm{H}), 4.10(\mathrm{~s}, 3 \mathrm{H}), 3.47(\mathrm{~s}, 3 \mathrm{H}), 2.66(\mathrm{t}, J=11.7 \mathrm{~Hz}, 1 \mathrm{H}), 2.42-2.24(\mathrm{~m}$, 2H), $2.17-1.97$ (m, 3H), 1.83 (d, J=12.9 Hz, 1H), $1.64-1.38$ (m, 6H), $1.28-1.02(\mathrm{~m}, 7 \mathrm{H})$, $0.92-0.74(\mathrm{~m}, 2 \mathrm{H}),-0.14--0.29(\mathrm{~m}, 1 \mathrm{H}) ;{ }^{31} \mathrm{P} \operatorname{NMR}\left(162 \mathrm{MHz}, \mathrm{CD}_{3} \mathrm{CN}\right) \delta=53.38$; IR (neat) $\bar{v}$ $=510,520,537,565,600,651,738,761,780,819,851,892,916,938,1001,1018,1045$, 1111, 1152, 1182, 1215, 1268, 1302, 1433, 1449, 1484, 1570, 1581, 1603, 2855, $2930 \mathrm{~cm}^{-1}$; HRMS calcd. for $\mathrm{C}_{37} \mathrm{H}_{45} \mathrm{~N}_{2} \mathrm{O}_{2} \mathrm{~F}_{6}$ SbPPd: 921.118882; found: 921.119940.

## Curriculum Vitae

Address: Sudetenweg 4d, 59065 Hamm, Germany

## Areas of Interests:

## Development and Improvement of Synthetic Methods, Catalyst Design, Total Synthesis

## Education:

| $01 / 2016-11 / 2017$ | Georg-August-Universität, Göttingen, Germany <br> Degree: Dr. rer. nat. (finished) <br> Major: Metal Organic Chemistry |
| :---: | :--- |
| $01 / 2015-12 / 2015$ | Max-Planck-Institut für Kohlenforschung, Mülheim, Germany <br>  <br> Major: X-Ray crystallography |
| 11/2012-12/2015 | Max-Planck-Institut für Kohlenforschung, Mülheim, Germany <br> Degree: Dr. rer. nat. (started) |
|  | Major: Metal organic Chemistry |
| $09 / 2010-09 / 2012$ | Technische Universität Dortmund, Germany <br> Degree: Master of Science |
|  | Major: Organic Chemistry |
| $09 / 2007-09 / 2010$ | Technische Universität Dortmund, Deutschland <br> Degree: Bachelor of Science <br> Major: Organic Chemistry |

## Academic Experience

Metal Organic Chemistry, Georg-August-Universität, Göttingen, Germany (Advisor: Prof. Alcarazo) and Max-Planck-Institut für Kohlenforschung, Mülheim, Germany (Advisor: Prof. Fürstner with Prof. Alcarazo)

## 11/2012-11/2016 Design, Synthesis and Applications of New Cationic Ligands of the $15^{\text {th }}$ Main Group Elements

- Design, Synthesis and Applications of Pyridinium Based Phosphine Ligands
- Single Crystal Structure Determination

Organic Chemistry, Technische Universität Dortmund, Germany (Advisor: Prof. Hiersemann)

# 09/2010-09/2012 To the Development of an Asymmetric Catalytic Kojic Acid Claisen Rearrangement 

- $\mu$ wave assisted or catalytic vinylogous Gosteli Claisen Rearrangement

09/2007-09/2010 To the Total Synthesis of Menverin C and F<br>- intramolecular thermal Carbonyl En Reaction for the Synthesis of a Cyclopentane Fragment

## Publications

- "Synthesis and reactivity of $\alpha$-cationic phosphines: the effect of imidazolinium and amidinium substituents", E. Haldón, Á. Kozma, H. Tinnermann, L. Gu, R. Goddard, M. Alcarazo, Dalton Trans. 2016, 45, 1872.
- "Synthesis, Structure, and Applications of Pyridiniophosphines", H. Tinnermann, C. Wille, M. Alcarazo, Angew. Chem. Int. Ed. 2014, 33, 8732
- "Synthese, Struktur und Anwendungen von Pyridiniumphosphanen", H. Tinnermann, C. Wille, M. Alcarazo, Angew. Chem. 2014, 33, 8877.

## Technical Skills

- Mastered the Operation of MS, NMR, HPLC, GC, TLC, IR, UV, XRAY, CV
- Mastered the Procedures of Organic, Inorganic Synthesis and Schlenk Techniques
- Highly Proficient in Reading and Writing Research Paper in English

## Personality

Responsible, Motivated, Cooperative, Conscientious

Hamm, 05.12.2017

Hendrik Tinnermann
