

# Ryanodine receptors in experimental autoimmune encephalomyelitis, an animal model of multiple sclerosis

Dissertation

Presented to the Faculty of Biology and Psychology  
of the Georg-August University of Göttingen in partial fulfillment  
of the requirements for the degree

‘Doctor rerum naturalium (Dr. rer. nat.)’

in the basic program ‘Biology’  
of the Georg-August University School of Science (GAUSS)

submitted by  
Manuel von Osten  
born in Eberbach

Göttingen,  
2015

Thesis committee members:

- 1<sup>st</sup> reviewer: Prof. Dr. Dr. Hannelore Ehrenreich, Clinical Neurosciences,  
Max Planck Institute of Experimental Medicine, Göttingen
- 2<sup>nd</sup> reviewer: Prof. Dr. Wolfgang Brück, Dept. of Neuropathology,  
University Medical Center, Göttingen
- Supervisor: Prof. Dr. Alexander Flügel, Dept. of Neuroimmunology,  
University Medical Center, Göttingen

Members of the examination board:

- 1<sup>st</sup> referee: Prof. Dr. Dr. Hannelore Ehrenreich, Clinical Neurosciences,  
Max Planck Institute of Experimental Medicine, Göttingen
- 2<sup>nd</sup> referee: Prof. Dr. Wolfgang Brück, Dept. of Neuropathology,  
University Medical Center, Göttingen

Additional members of the examination board

Prof. Dr. Alexander Flügel, Dept. of Neuroimmunology,  
University Medical Center, Göttingen

Prof. Dr. Mikael Simons, Cellular Neuroscience, Max Planck  
Institute of Experimental Medicine, Göttingen

Prof. Dr. Hauke Werner, Neurogenetics, Max Planck Institute  
of Experimental Medicine, Göttingen

Prof. Dr. Jürgen Wienands, Dept. of Cellular and Molecular  
Immunology, University Medical Center, Göttingen

Date of examination: 26<sup>th</sup> June 2015

# Affidavit

Herewith I declare that my doctoral thesis entitled 'Ryanodine receptors in experimental autoimmune encephalomyelitis, an animal model of multiple sclerosis' has been written independently with no other sources and aids than quoted.

Manuel von Osten

# Abbreviations

Abs	Antibodies
AC	Astrocyte
APC	Antigen-presenting cell
ATP	Adenosine triphosphate
BBB	Blood-brain barrier
BCR	B cell receptor
BMC	Bone marrow chimera
Ca <sup>2+</sup>	Calcium (ions)
cADPR	Cyclic ADP-ribose
CD	Cluster of differentiation
cDNA	Complementary DNA
CICR	Calcium-induced calcium release
CNS	Central nervous system
CRAC	Calcium release activated calcium channel
CREB	cyclic-AMP-responsive-element-binding protein
CSF	Cerebrospinal fluid
Cntr, Ctrl	Control
cpm	counts per minute
DAG	Diacylglycerol
DC	Dendritic cell
DKO	Double knockout
DNA	Deoxyribonucleic acid
EAE	Experimental autoimmune encephalomyelitis
ER	Endoplasmic reticulum
FACS	Fluorescence-activated cell sorting
FLC	Fetal liver chimera
GFP	Green fluorescent protein
Glu	Glutamate

GM-CSF	Granulocyte macrophage colony-stimulating factor
Iba1	ionized calcium-binding adapter molecule 1
ICAM-1	Intercellular adhesion molecule-1
ICC	Immunocytochemistry
ICH	Immunohistochemistry
Ig	Immunoglobulin
i.p.	intraperitoneally
IP <sub>3</sub>	D-myo-inositol 1,4,5-trisphosphate
IP <sub>3</sub> R	IP <sub>3</sub> receptor
i.v.	intravenously
IFN- $\gamma$	Interferon gamma
IL-2	Interleukin-2
IL-17	Interleukin-17
KO	knockout
LFA-1	Lymphocyte function-associated antigen-1
LFB	Luxol fast blue
LN	Lymph node
LPS	Lipopolysaccharide
MBP	Myelin basic protein
Med	Medium
MEF2	myocyte enhancer factor 2
MG	Microglia
MH	Malignant hyperthermia
MHC	Major histocompatibility complex
MOG	Myelin oligodendrocyte glycoprotein
mRNA	Messenger RNA
MS	Multiple sclerosis
NAADP	nicotinic acid adenine dinucleotide phosphate
NAD <sup>+</sup>	nicotinamide adenine dinucleotide
nd	Not detectable
Neu	Neuron
ns	non-significant

NFAT	nuclear factor of activated T cells
NF- $\kappa$ B	nuclear factor kappa-light-chain-enhancer of activated B cells
ORAI1	calcium release-activated calcium channel protein 1
OVA	Ovalbumin
PAS	Periodic acid-Schiff
PCR	Polymerase chain reaction
p. i.	Post-immunization
PIP <sub>2</sub>	Phospholipid phosphatidylinositol 4,5-bisphosphate
PKC	Protein kinase C
PLC	Phospholipase C
PLP	Proteolipid protein
PPMS	Primary progressive
PRMS	Progressive-relapsing MS
PSGL-1	P-selectin glycoprotein ligand-1
RFP	Red fluorescent protein
RNA	Ribonucleic acid
RRMS	Relapsing-remitting MS
RyR	Ryanodine receptor
SEM	Standard error of the mean
SOC	store-operated channel
SOCE	store-operated channel calcium entry
SPMS	Secondary progressive MS
SR	Sarcoplasmic reticulum
STIM1	stromal interaction molecule-1
TCR	T cell receptor
Th	helper T cell
TNF- $\alpha$	Tumor necrosis factor alpha
TPC	Two-pore channel
VCAM-1	Vascular cell adhesion protein-1
VLA-4	Very late antigen-4
WT	Wild type

# Abstract

The activation of auto-aggressive T cells is crucial for the development of autoimmune diseases, such as multiple sclerosis (MS) or its animal model experimental autoimmune encephalomyelitis (EAE). T cell activation relies on stimulation of the T cell receptor by antigen and results in rapid release of calcium ( $\text{Ca}^{2+}$ ) from the endoplasmic reticulum (ER) into the cytosol. This process is mediated by  $\text{IP}_3$  receptors and, possibly by ryanodine receptors (RyRs). The release of  $\text{Ca}^{2+}$  from the ER into the cytosol follows a second influx of  $\text{Ca}^{2+}$  across the plasma membrane through  $\text{Ca}^{2+}$  release activated  $\text{Ca}^{2+}$  channels (CRAC). This store-operated calcium entry (SOCE) mediates further signal transduction by the activation of  $\text{Ca}^{2+}$  sensitive enzymes, such as calcineurin, which then leads to transcription and production of T cell characteristic cytokines.

Even though EAE in mice is in many aspects a well studied model, the role of RyRs has not yet been addressed in context of the disease. Previous studies using loss-of-function techniques unveiled the importance of RyR1 and RyR3 for NAADP mediated  $\text{Ca}^{2+}$  signaling in Jurkat cells, and in rat adoptive transfer EAE by pharmacological antagonism of NAADP, a putative ligand for RyR1.

In the present study we found that the gene encoding for the RyR1 isoform is expressed in antigen-experienced effector, but not in naïve mouse T cells. Genetic deletion of *Ryr1* studied in fetal liver chimeric mice did not result in overt immune phenotype, however *Ryr1* deficient T lymphocytes show diminished  $\text{Ca}^{2+}$  signaling and reduced proliferation in response to TCR stimulation. This supported the observation that these animals developed less severe active EAE than control mice.

Although our data indicate that RyR3 does not play a major role in T cells, yet we observed attenuated clinical EAE and CNS histopathology in mice with a whole-body knockout for the *Ryr3* gene. There however, we have excluded that *Ryr3* deficiency in T cells is responsible for mitigated neuroinflammation using chimeric mice and T cell transfer experiments. Instead we observed that *Ryr3* deficient astrocytes display alteration in stimulated  $\text{Ca}^{2+}$  signaling *in vitro*, produce less chemokines in response to inflammatory stimuli *in vitro* but also in the inflamed CNS tissue, that limits infiltration of immune cells and associated tissue damage. We also demonstrate that pharmacological inhibition of RyR function has beneficial effects on the EAE disease. Thus, ryanodine receptors seem to play critical roles during autoimmune disease of the CNS (RyR1 in T cells whereas RyR3 in astrocytes) and can be considered as therapeutic targets.

# 1 Introduction

## 1.1 Multiple sclerosis

Multiple sclerosis (MS) is a chronic autoimmune disorder affecting the central nervous system (CNS), where the immune system damages and destroys the protecting myelin sheaths of the neurons in brain and spinal cord, resulting in demyelination and axonal loss (CALABRESI, 2004, LOMA and HEYMAN, 2011). The disease then manifests in cortical lesions (plaques) in the brain's white matter. It is the most commonly diagnosed neurologic disease in young adults at ages between 20 and 40, occurring twice as frequently in women as in men. The total number of individuals with MS is estimated to around 2.5 million worldwide (COMPSTON AND COLES, 2008). The disease appears highly heterogenic in terms of clinical symptoms, disease course and pathology, as well as the response to therapies. MS symptoms are very variable and affect each patient differently. The first symptoms, used to identify MS, commonly present as blurred vision, and impairment of mobility and balance (due to muscle atrophy). Patients with established MS suffer from increasing gait abnormalities, loss of vision and impaired body coordination that may worsen over time to a severe paralysis. In addition, extreme fatigue, bladder dysfunction and pain can occur during MS (GOLDENBERG, 2012; CREE, 2014). The cause of MS is unknown, but a combination of genetic susceptibility and a non-genetic triggers are discussed (BARCELLOS *et al.*, 2003, WILLER *et al.*, 2003, HANDEL *et al.*, 2010). First degree relatives and twins are 40-fold more susceptible to MS suggesting a genetic basis (BARCELLOS *et al.*, 2003). Exposure to infectious agents like viruses, e.g. Epstein-Barr-Virus, or some mycoplasma strains, e.g. *mycoplasma pneumoniae*, but also smoking or sunlight exposure/vitamin D levels are discussed as environmental risk factors that can induce a self-sustaining autoimmune disorder and favoring MS (CREE, 2014).

According to its disease progress, MS is categorized into four major variants (HAUSER and GOODWIN, 2008):

1. *Relapsing-remitting MS (RRMS)*: With a prevalence of 85 %, RRMS is the most occurring form of MS, characterized by abrupt disease phases (relapses) 1–2 times a year and disease-free phases, in that the patients show improved or no symptoms (remission).
2. *Secondary progressive MS (SPMS)*: This variant may develop in patients with RRMS. In SPMS, patients suffer from continuous progression of disability occurring after a MS relapse.
3. *Primary progressive MS (PPMS)*: PPMS affects about 10 % of MS patients. It is characterized by continuous disease progression

## Introduction

without any relapse or remission periods.

4. *Progressive-relapsing MS (PRMS)*: About 5 % of MS patients develop this rare variant. It starts directly progressive, with intermediate relapses but no remissions and straight worsening along the course of disease.

There is no curative treatment for MS patients so far, partly due to the fact that many aspects of MS etiology remain elusive. Current treatments focus on modulation of the immune system but come along with significant side effects (LOMA and HEYMAN, 2011). Moreover, long-term studies on newer therapies are pending. Therefore, conceiving the complex etiology of MS is most important for an effective and safe treatment of MS patients.

## 1.2 Experimental autoimmune encephalomyelitis

The heterogeneity of MS complicates the research. To understand the molecular and cellular mechanisms that drive the disease and to identify new possible therapeutic targets require an experimental model that mimics certain aspects of neuroinflammation relevant for MS. In rodents, there are three clinically relevant and established disease models of MS. Demyelination evoked by viral infection—such as Theiler's Murine Encephalitis Virus or Semliki Forest Virus—is a helpful tool to model the viral motive of MS and leads to a progressive CD4<sup>+</sup> T cell mediated demyelinating disease (DONATI AND JACOBSON, 2002). Cuprizone treatment in mice is a model of toxic demyelination and is evoked by feeding young mice with the copper chelator cuprizone, that leads to oligodendrocyte death and reversible demyelination (TORKILDSEN *et al.*, 2008). The most commonly used animal model of MS, however, is experimental autoimmune encephalomyelitis (EAE; ROBINSON *et al.*, 2014). It requires active immunization against myelin antigens (active EAE) or the adoptive transfer of pathogenic effector T cells into naïve recipients (transfer EAE; MILLER *et al.*, 2007). Active EAE is induced by the administration of myelin peptides, such as myelin basic protein (MBP), myelin oligodendrocyte glycoprotein (MOG) or proteolipid protein (PLP) in adjuvant in susceptible mouse strains. By contrast, transfer ('passive') EAE is induced by transferring encephalitogenic, myelin-specific CD4<sup>+</sup> T cell blasts into donor mice (MILLER *et al.*, 2007).

In active EAE, immunization against myelin antigens leads to the priming of myelin-specific T cells in the secondary lymphoid organs. Succeeding activation, T cells rapidly proliferate and differentiate into effector cells and become licensed to exit the secondary lymphoid organs through the efferent

## Introduction

lymphatic vessels to enter the blood circulation. The expression of adhesion molecules and integrins allows T cells to overcome the blood-brain barrier (BBB), where they come in contact with CNS-resident antigen presenting cells (APCs), recognize endogenously expressed antigens and become reactivated. This leads to the expression and secretion of the proinflammatory cytokines IFN- $\gamma$ , IL-17, GM-CSF and TNF- $\alpha$  by effector T cells (O'CONNOR *et al.*, 2008; KROENKE *et al.*, 2008). This leads to a disruption of the BBB and additional production of chemokines that in turn facilitate the recruitment of monocytes, macrophages, neutrophils and  $\gamma\delta$ T cells into the CNS (GOVERMAN, 2009). These inflammatory cells cause and mediate damage to the myelin sheaths and axons, and are mainly responsible for the formation of lesions and the breakdown of the neuronal network within the CNS.

In transfer EAE, activated myelin-specific Th1, Th17 or mixed Th1/Th17 CD4<sup>+</sup> T cell blasts from immunized donor mice are injected into naïve recipient animals. By that, the effector phase of EAE can be modeled directly and it also allows the tracking of genetically labeled encephalitogenic T cells *in vivo* (JÄGER *et al.*, 2009). The latter approach is a powerful tool to analyze T cell specific roles of a gene of interest.

Mice develop variable forms of EAE depending on the genetic background of the animals as well as the administered antigen. Active EAE induction with MOG protein or the T cell epitope MOG<sub>35-55</sub> (MEVGWYRSPFSRVVHLYRNGK) in C57Bl/6 mice leads to a chronic form of the disease starting between days 9–12 post immunization with characteristic inflammatory foci appearing predominantly in the spinal cord rather than in brain (MENDEL *et al.*, 1995). In contrast, immunization against the T cell epitope PLP<sub>139-151</sub> (HCLGKWLGHDPKF) in SJL/J mice leads to a relapsing-remitting form of EAE (MCRAE *et al.*, 1992). The generation of transgenic mice with deletion or over-expression of immunological relevant genes enlarged the experimental possibilities for studies on EAE. Examples of such genes are those encoding T cell receptors (TCRs) or major histocompatibility complex (MHC) molecules. Of particular interest is the model of spontaneous EAE. This specific variant of EAE occurs in mice that were generated by crossing MOG-specific TCR transgenic mice with MOG-specific Ig heavy-chain knock-in mice with an incidence of 59 % (KRISHNAMOORTHY *et al.*, 2006; BETTELLI *et al.*, 2006). Disease induction in these mice proceeds completely spontaneously and overcomes the artificial component of immunization or transfer of pre-activated T lymphocytes. That brings it closer to the human disease MS and is of great advantage when studying the triggers of CNS autoimmunity (Betelli *et al.*, 2006), however it is difficult to study early T cell infiltration in the preclinical stage of disease in this model, as the onset time is unpredictable.

### 1.3 The CNS and the blood-brain barrier

The CNS is a highly specialized and complex organ in aspects of physiology, neuroanatomy and immunology. It is considered as 'immune privileged', even though this term is under debate among neuroscientists (CARSON *et al.*, 2006; HARRIS *et al.*, 2014). The immune privilege was first described by Sir Peter Brian Medawar in 1948, when he demonstrated that allografts from mouse skin better persisted in eye and brain than in tissues from the periphery (MEDAWAR, 1948). For the CNS, immune privilege has been long characterized by the lack of lymphatic vessels and a surrounding endothelial barrier restricting immune cell contact (ILIFF AND NEDERGAARD, 2013). Furthermore, the low level expression of MHC molecules was considered as another evidence for the brain being an immunologically privileged site. Yet, as mentioned above, the term 'immune privilege' is under debate, because recent results suggest that the brain is capable of both immune and autoimmune reactions as well (RIVEST *et al.*, 2009). This was supported by the discovery of MHC molecule expression on microglia and astrocytes (NEUMANN *et al.*, 1996). While these cell populations usually express MHC molecules only at low levels, up-regulated expression can be found under inflammatory conditions that may be critical for antigen presentation. Reactive microglia and astrocytes with increased MHC-II expression have been reported in several neurological diseases (MARAGAKIS AND ROTHSTEIN, 2006; MCGEER *et al.*, 1993).

The CNS is surrounded by the meninges, a set of membranes that consist of three layers termed the dura mater, the arachnoid mater and the pia mater. The dura mater is the membrane closest to the skull (brain) or the epidural space (spinal cord). The arachnoid and pia mater together are named the leptomeninges. They form the subarachnoid space in between, which is occupied by the cerebrospinal fluid (CSF). The CSF is produced in the choroid plexus and circulates within the ventricular system of the brain. It provides nutrients and acts as some kind of fluid dampening system additionally protective for the brain. The pia mater is the membrane that lies on the outer surface of the brain and spinal cord. Capillaries from blood vessels run through the pia mater, thereby sustaining the CNS.

The blood-brain barrier (BBB) is separating the CNS from the blood circulation and is composed of endothelial cells, an underlying basement membrane and the astrocytic endfeet. These astrocytic foot processes associate with a second basement membrane to create the glia limitans (glial limiting membrane) surrounding the endothelial cells of the BBB. These endothelial cells are connected by impermeable tight junctions that ensure that the brain is being shielded from soluble molecules (including antibodies) circulating through the blood vessels. Under neuroinflammatory conditions, the astrocytes of the glia limitans and the endothelial cells are also known as producers of chemokines and proinflammatory cytokines (CHOI *et al.*, 2014).

## 1.4 Leukocyte infiltration into the CNS

The migration of leukocytes from the blood circulation into infected or damaged tissue is called extravasation or diapedesis. In case of MS or EAE, leukocytes first have to overcome the BBB before entering the CNS. This makes it different from leukocyte extravasation in the periphery, where such barriers are missing. Several routes have been described for leukocyte extravasation into the CNS. The major one is from the blood into the parenchymal perivascular space through the BBB, while a second site of entry into the CNS is via the choroid plexus into the CSF (RANSOHOFF *et al.*, 2003).

The interplay between leukocytes and the endothelium of the BBB that finally leads to diapedesis is described as a multistep process, in which different certain molecules on both leukocytes and endothelial cells are involved (ENGELHARDT AND RANSOHOFF, 2012). First, leukocytes come in contact with the endothelium. This step is termed ‘tethering’ or ‘capture’ and is mediated by P-selectin glycoprotein ligand-1 (PSGL-1) on leukocytes and its respective selectin counterparts on the vessel endothelium (AUSTRUP *et al.*, 1997). Integrins—including very late antigen-4 (VLA-4,  $\alpha 4\beta 1$ ) and lymphocyte function-associated antigen 1 (LFA-1,  $\alpha L\beta 2$ )—as well as the adhesion molecules vascular cell adhesion protein-1 (VCAM-1) and intercellular adhesion molecule-1 (ICAM-1) support capturing of leukocytes and mediate the next step of leukocyte locomotion, which is the rolling of leukocytes on the vessel endothelium (LEY *et al.*, 2007). Rolling of leukocytes comes to a stop once leukocytes recognize glycosaminoglycan bound chemokines on the endothelium that are produced locally or were translocated to the cellular surface (MIDDLETON *et al.*, 2002). Chemokine binding induces conformational changes in integrins, leading to firm adhesion (‘attachment’) of leukocytes to the vessel endothelium. Next, leukocytes start to crawl—mainly against the blood flow—to locate a spot for extravasation. Thereby, leukocytes undergo a phenotypical change from spherical to a rather flattened shape. The firm adhesion is thereby necessary due to constant shear stress of the blood flow (LAWRENCE *et al.*, 1987). VLA-4 seems to be a crucial factor for intraluminal crawling, since treatment with VLA-4 depleting antibodies prevented leukocytes from crawling and extravasation, in contrast to LFA-1, whose depletion did not critically alter leukocytes transmigration (BARTHOLOMÄUS *et al.*, 2009). Finally, diapedesis can occur paracellular through endothelial junctions, or transcellular through the body of endothelial cells (LEY *et al.*, 2007).

After successful diapedesis, leukocytes scan the leptomeningeal area for their respective antigen and come in contact with resident perivascular and meningeal phagocytes, which are potential APCs. After recognition of the antigen, leukocytes become reactivated. In case of T cells, they upregulate proinflammatory cytokines (IFN- $\gamma$ , IL-17, TNF- $\alpha$ , and IL-2) and surface

markers (OX40, IL-2R; BARTHOLOMÄUS *et al.*, 2009), which allows them to penetrate deep into the spinal cord parenchyma and establish inflammation. However, the release of cytokines by infiltrating T cells may activate microglia and also astrocytes, that are beside endothelial cells involved in maintaining the integrity of the BBB, to cause the release of certain immunomodulators such as chemokines at the pathological site. This further may compromise the BBB, which is becoming permeable to peripheral immune cells, including lymphocytes and myeloid cells. As a result, the inflammation is further exacerbated and supports the generation of a chronic neuroinflammatory disease (TRAN *et al.*, 2000; FLÜGEL *et al.*, 2001; KAWAKAMI *et al.*, 2004).

### 1.5 Store-operated calcium entry

As an important intracellular messenger, calcium ( $\text{Ca}^{2+}$ ) exerts functions in almost every cell type (BOOTMAN *et al.*, 2001). It is involved in muscle contraction, neurotransmitter signaling and synaptic plasticity. In addition to that, calcium regulates the activity of calcium sensitive enzymes and by that conducting a wide range of downstream signaling pathways (BERRIDGE *et al.*, 2000). The calcium concentration within the cytoplasm is usually low, being in the range of 100 nM ('resting state'), which is maintained by ion pumps that actively export  $\text{Ca}^{2+}$  into the extracellular space or sequester  $\text{Ca}^{2+}$  into store organelles first of all the endoplasmatic reticulum (ER). Upon specific stimuli  $\text{Ca}^{2+}$  is rapidly released from the ER and enters the cytoplasm through plasma membrane ion channels (ENDO, 2009). Calcium signaling is initiated in many cell types by activation of the phospholipase C (PLC) pathway (SCHMIDT *et al.*, 2001). This particular enzyme can be activated by many cell surface receptors, including G protein coupled receptors and tyrosine kinases. PLC catalyses the hydrolysis of the membrane phospholipid phosphatidylinositol 4,5-bisphosphate ( $\text{PIP}_2$ ) into D-*myo*-inositol 1,4,5-trisphosphate ( $\text{IP}_3$ ) and diacylglycerol (DAG).  $\text{IP}_3$  and DAG exert their functions as second messengers. While DAG activates protein kinase C (PKC) and by this several downstream signaling pathways,  $\text{IP}_3$  binds to ER membrane bound  $\text{IP}_3$  receptors ( $\text{IP}_3\text{Rs}$ ), which are  $\text{Ca}^{2+}$  channels itself, leading to the release of  $\text{Ca}^{2+}$  from the ER internal stores. In brief, this  $\text{Ca}^{2+}$  efflux activates 'store-operated channels' (SOCs) on the plasma membrane which provokes further  $\text{Ca}^{2+}$  entry from outside the cell. This results in a rapid increase in intracellular  $\text{Ca}^{2+}$  to a concentration of 1000 nM ('activated state') (CLAPHAM, 2007). The  $\text{Ca}^{2+}$  regulated enzyme calmodulin ('calcium-modulated protein') is one major downstream target of store-operated calcium entry (SOCE) and a potent mediator for the physiological effects of  $\text{Ca}^{2+}$  signaling.

## 1.6 $\text{Ca}^{2+}$ signaling in T lymphocytes

$\text{Ca}^{2+}$  ions and their respective channels and transporters are essential for T lymphocytes in that they regulate cell differentiation, effector function and gene transcription (OH-HORA and RAO, 2008).

**Fig. 1.1** | Calcium signaling in T lymphocytes. Following formation of the peptide:MHC-TCR complex, PLC activation mediates production of second messenger IP<sub>3</sub> binds and activates to ER calcium channels, thereby depleting Ca<sup>2+</sup> from the store. This depletion via STIM1 protein activates CRAC/ORAI channels on the cell membrane and triggers a massive influx of Ca<sup>2+</sup> into the cytosol from extracellular space. As a result, calcineurin phosphatase becomes activated and induces NFAT translocation into the nucleus by dephosphorylation. In the nucleus NFAT mediates specific gene expression. Ca<sup>2+</sup>, calcium ion; [Ca<sup>2+</sup>]<sub>i</sub>, intracellular calcium concentration; cADPR, cyclic ADP-ribose; CRAC, calcium release activated channel; ER, endoplasmic reticulum; IP<sub>3</sub>, inositol-3-phosphate; IP<sub>3</sub>R, inositol-3-phosphate receptor; MHC, major histocompatibility complex; NAADP, nicotinic acid adenine dinucleotide phosphate, NFAT, nuclear factor of activated T cells; ORAI1, calcium release-activated calcium channel protein 1; RyR, ryanodine receptor; STIM1, stromal interaction molecule-1; TCR, T cell receptor.

## Introduction

Stimulation of the T cell receptor leads to the activation of phospholipase  $\text{C}\gamma 1$  ( $\text{PLC}\gamma 1$ ) and the generation of  $\text{IP}_3$  (FESKE *et al.*, 2012), which triggers the release of  $\text{Ca}^{2+}$  from the ER stores into the cytosol. This sudden release of  $\text{Ca}^{2+}$  is sensed by stromal interaction molecule 1 (STIM1) and STIM2 on the ER membrane, leading to activation of calcium release-activated calcium channel protein 1 (ORAI1), ORAI2 and ORAI3 that are located on the plasma membrane and build the pore of the calcium release-activated channel (CRAC; FESKE *et al.*, 2006). The increase in  $\text{Ca}^{2+}$  concentration occurs within 30–60 seconds (WÜLFING *et al.*, 1998) and induces the activation of a series of transcription factors, including cyclic-AMP-responsive-element-binding protein (CREB), myocyte enhancer factor 2 (MEF2) and nuclear factor of activated T cells (NFAT). NFAT signaling is of great significance in T cells (MACIAN, 2005; LODYGIN *et al.*, 2013). This particular transcription factor is activated by dephosphorylation, which is carried out by calcineurin, a serine/threonine phosphatase. Calcineurin activation is a two-step process. Increase of free cytosolic  $\text{Ca}^{2+}$  leads to the dissociation of the auto-inhibitory domain of calcineurin, which is mediated by a  $\text{Ca}^{2+}$  dependent conformational change of this subunit by that exposing the  $\text{Ca}^{2+}$ /calmodulin binding site of the protein. Binding of activated calmodulin to this site triggers another conformational change of calcineurin and full activation of the enzyme. The dephosphorylated NFAT then translocates into the nucleus and induces transcription of T cell characteristic pro-inflammatory cytokines, e.g. IL-2 and IFN- $\gamma$  (HOGAN *et al.*, 2003). In contrast to nuclear factor- $\kappa\text{B}$  (NF- $\kappa\text{B}$ ), that functions even at a transient increase of  $\text{Ca}^{2+}$  concentration, NFAT-dependent gene transcription requires strong and prolonged intracellular  $\text{Ca}^{2+}$  boosts, suggesting multiple regulatory mechanisms of  $\text{Ca}^{2+}$  signaling in T cells (KANNO AND SIEBENLIST, 1996; FESKE *et al.*, 2001; FISCHER *et al.*, 2001).

## 1.7 Intracellular $\text{Ca}^{2+}$ release channels

The sarcoplasmic reticulum (SR) and the ER are the main stores for intracellular  $\text{Ca}^{2+}$  in striated muscle cells or other cell types, respectively. Its release is performed by two major classes of receptors that have been identified on the SR/ER membrane, termed  $\text{IP}_3$  receptors ( $\text{IP}_3\text{Rs}$ ) and ryanodine receptors (RyRs). A third class of receptors is the target of the more recently identified second messenger NAADP (LEE and AARHUS, 1995; CHURCHILL AND GALIONE, 2000; GALIONE, 2011).

$\text{IP}_3\text{Rs}$  were the first purified calcium-induced  $\text{Ca}^{2+}$  release (CICR) channels (SUPATTAPONE *et al.*, 1988) and hence studied intensively in their role of converting external signals into intracellular  $\text{Ca}^{2+}$  responses. They are diversely expressed and play a role in several cellular and physiological

## Introduction

processes including cell proliferation, behavior, memory and learning (BOSANAC *et al.*, 2002). IP<sub>3</sub> binding to IP<sub>3</sub>Rs is essential for Ca<sup>2+</sup> release from the ER (BERRIDGE, 1997). However, IP<sub>3</sub>Rs are highly regulated ion channels. They are modulated by phosphorylation, accessory proteins, adenosine triphosphate (ATP) and, most importantly, Ca<sup>2+</sup> itself (GRAFTON and THWAITE, 2001). Three isoforms of IP<sub>3</sub>Rs are known, differing in their sensitivity to regulation by Ca<sup>2+</sup>. The possibility of the cell to modulate CICR in such a distinct manner emphasizes the significance of intracellular Ca<sup>2+</sup> signaling via IP<sub>3</sub>Rs as a 'spatial-temporal' event (THOMAS *et al.*, 1996, YULE, 2001). *Ip3r1*<sup>-/-</sup> mice are rarely born alive, and adult mice lacking *Ip3r1* were suffering from severe neurological symptoms (MATSUMOTO AND NAGATA, 1999). Experiments with bone marrow chimeras show that IP<sub>3</sub>R1 is dispensable for T cell activation and Ca<sup>2+</sup> signaling (HIROTA *et al.*, 1998). Studies on mice with deletion of the *Ip3r2* and/or *Ip3r3* gene showed the importance of these receptors for the generation of Ca<sup>2+</sup> signals in astrocytes (SRINIVASAN *et al.*, 2015). The importance of IP<sub>3</sub>Rs in the context of EAE has not yet been reported so far.

Besides IP<sub>3</sub>, nicotinic acid adenine dinucleotide phosphate (NAADP) and cyclic ADP-ribose (cADPR) are important second messengers for Ca<sup>2+</sup> signaling within T cells (GUSE, 1999; BOOTMAN *et al.*, 2002). Both NAADP and cADPR are metabolites of nicotinamide adenine dinucleotide (NAD<sup>+</sup>; LEE *et al.*, 1989). Discovered in 1999 by CANCELA *et al.* in pancreatic cells, NAADP was observed to trigger Ca<sup>2+</sup> release from the ER after releasing Ca<sup>2+</sup> from much smaller, lysosomal acidic stores (CHURCHILL *et al.*, 2002). This is underlined by the characteristic of NAADP being a rather short-lived second messenger and it is assumed that it acts before IP<sub>3</sub> and cADPR exert their messaging function (KINNEAR *et al.*, 2004, KINNEAR *et al.*, 2008, ERNST *et al.*, 2013). It was demonstrated in Jurkat T cells that NAADP emerges rapidly after stimulation of the TCR/CD3 complex (LEE, 2001; GASSER *et al.*, 2006) and provides the very first local Ca<sup>2+</sup> signals. These signals are thought to 'prime' IP<sub>3</sub>Rs and RyRs before IP<sub>3</sub> and cADPR provide amplifying signals for Ca<sup>2+</sup> release (GUSE *et al.*, 1995, GALIONE, 2011). Yet, a distinct allocation of NAADP to a specific receptor is still under investigation (HOHENEGGER *et al.*, 2002; GALIONE, 2011; OGUNBAYO *et al.*, 2011). Even though evidences point out the family of two-pore channels (TPCs) to be a potential candidate as receptors for NAADP (ISHIBASHI *et al.*, 2000; CALCRAFT *et al.*, 2009), data of human T cells were presented in that RyRs are required for functional Ca<sup>2+</sup> signaling (LANGHORST *et al.*, 2004), and that in Jurkat T cells RyR1 worked out as the primary target of NAADP (DAMMERMANN *et al.*, 2009).

cADPR and its non-cyclic form ADPR are produced from NAD<sup>+</sup> by ADP-ribosyl cyclases (PETERSEN AND CANCELA, 1999). Equally to NAADP, it is generated after TCR/CD3 ligation (GUSE *et al.*, 1995, GUSE, 1999) but acts directly on RyRs in Jurkat T cells (SCHWARZMANN *et al.*, 2002). There, it induces Ca<sup>2+</sup> entry and makes RyRs more sensitive to further Ca<sup>2+</sup> and creates prolonged Ca<sup>2+</sup> signals (LEE, 2001).

## 1.8 Ryanodine receptors

Ryanodine receptors (RyRs) are named after the plant alkaloid ryanodine, which binds to RyRs with high affinity (IMAGAWA *et al.*, 1987). To our current knowledge, RyRs are the largest known ion channels (TAKESHIMA *et al.*, 1989). One receptor consists of four subunits, each approximately 565 kDa in weight, together forming a homotetramer of about 2.3 MDa (**Fig 1.1**; ZALK *et al.*, 2015).

**Fig. 1.2** | 3D structure of the mammalian RyR1 homotetramer determined by cryoelectron microscopy at a resolution of 4.8 Å. One protomer chain with its different domains is highlighted in color. *Left panel*: View in the plane of the SR membrane. *Right panel*: View from the cytosol. Figures from ZALK *et al.*, 2015.

### 1.8.1 Ryanodine receptor isoforms

Three RyR isoforms have been identified, termed skeletal RyR (RyR1), cardiac RyR (RyR2) and brain RyR (RyR3) after their major compartment of expression. RyRs are located on the membranes of intracellular  $\text{Ca}^{2+}$  stores, either the SR or the ER and release  $\text{Ca}^{2+}$  from those stores upon stimulation. All isoforms of RyRs can be activated by cADPR and  $\text{Ca}^{2+}$  itself. While cADPR is the main agonist for RyRs (LEE, 2001), ERNST *et al.* (2013) suggest a possible role of NAADP as a ligand for RyRs in Jurkat T cells. Beside their major expression compartments, RyRs are also expressed in other cell types or tissues, respectively, including the immune system. The expression of RyRs has been identified in different lymphocyte subsets and some mononuclear cells (**Table 1.1**). Of special importance for this thesis was the discovery of RyR expression in Lewis rat effector T cells (DAMMERMANN *et al.*, 2009). It was the first study on RyR expression in rodent T cells. There, expression of RyRs is restricted to effector, in contrast to naïve or memory T cells (CORDIGLIERI *et al.*, 2010). Furthermore, it was demonstrated that certain

subtypes of RyRs, namely RyR1 and RyR3, but not RyR2 are expressed in rat effector T cells, even though RyR3 was expressed to a lesser extent than RyR1 (DAMMERMANN *et al.*, 2009, CORDIGLIERI *et al.*, 2010).

**Table 1.1** | Expression of ryanodine receptor isoforms in immune cells

Cell type	RyR1	RyR2	RyR3
Jurkat T cells	GUSE <i>et al.</i> , 1999	—	HAKAMATA <i>et al.</i> , 1994, GUSE <i>et al.</i> , 1999
CD3 <sup>+</sup> T cells (Human)	THAKUR <i>et al.</i> , 2012	HOSOI <i>et al.</i> , 2001, THAKUR <i>et al.</i> , 2012	THAKUR <i>et al.</i> , 2012
CD19 <sup>+</sup> B cells (Human)	HOSOI <i>et al.</i> , 2001, SEI <i>et al.</i> , 2001	—	—
CD14 <sup>+</sup> monocytes (Human)	HOSOI <i>et al.</i> , 2001	—	—
Dendritic cells (C57Bl/6)	O'CONNELL <i>et al.</i> , 2002	—	—
MBP-specific effector T cells (Lewis rat)	CORDIGLIERI <i>et al.</i> , 2010	—	CORDIGLIERI <i>et al.</i> , 2010

### 1.8.2 Agonists and antagonists for ryanodine receptors

To unravel the properties of RyRs as intracellular Ca<sup>2+</sup> channels, a series of pharmacological studies has been performed, either with RyR agonists or antagonists, respectively. In this context, the pharmacological blocking of RyRs or the initiation of Ca<sup>2+</sup> release from the SR/ER was the central aspect of the studies.

The alkaloid ryanodine is maybe the most notably and most intensively studied ligand for RyRs (**Fig. 1.3, A**). Ryanodine is found in the South American plant *Ryania speciosa* and shows high binding affinity to RyRs, which was used to designate this class of receptors (MEISSNER, 1986, LAI *et al.*, 1988). It is a highly specific modulator of RyRs with bilateral properties. At nanomolar concentrations, ryanodine locks RyRs in their half-open state, causing Ca<sup>2+</sup> release, while concentrations in the micromolar range irreversibly block RyRs and prevent channel opening (LINDSAY *et al.*, 1994, TINKER *et al.*, 1996, WELCH *et al.*, 1997). Another RyR blocker is tetracaine (**Fig. 1.3, B**), which is used as a local anesthetic (ZUCCHI and RONCA-TESTONI, 1997). Similar to ryanodine, tetracaine blocks RyRs completely at high concentrations (>1.25 mM, GYÖRKE *et al.*, 1997) but inhibits Ca<sup>2+</sup> release reversibly at low concentrations (0.25–1.25 mM, OVEREND *et al.*, 1998).

Dantrolene (**Fig. 1.3, C**) was first described in 1967 as a muscle relaxant and

## Introduction

was used to treat malignant hyperthermia (MH), a rare but life-threatening form of muscle dysfunction (SNYDER *et al.*, 1967) that is triggered during treatment with general anesthetics. In MH, patients are suffering from drastic disorders in skeletal muscle oxidative metabolism, affecting its ability to regulate body temperature, to supply oxygen and to remove carbon dioxide, which may then lead to acidosis, organ failure and eventually, death (ROSENBERG *et al.*, 2007). MH is an autosomal dominant inherited disease. In 50–70 % of MH patients, mutations have been identified on the gene coding for RyR1, that affect its closing mechanism and thereby raising intracellular  $\text{Ca}^{2+}$  levels by excessive  $\text{Ca}^{2+}$  mobilization from the SR (GILLARD *et al.*, 1992). The disorder is then therapeutically antagonized by dantrolene. Even though the mechanism of RyR1 inhibition by dantrolene is not yet completely understood, a direct effect on the RyR1 isoform has been implicated (ZHAO *et al.*, 2001, KOBAYASHI *et al.*, 2010). Furthermore, it was demonstrated that dantrolene may act on RyR3 as well, but not on RyR2 (ZHAO *et al.*, 2001).

**Fig. 1.3** | Skeletal formulas of selected RyR antagonists that block RyR mediated  $\text{Ca}^{2+}$  release. **(A)** Ryanodine. **(B)** Tetracain. **(C)** Dantrolene.

Caffeine (**Fig. 1.4, A**) was the first discovered pharmacological substance to initiate  $\text{Ca}^{2+}$  release from intracellular stores via RyRs (ENDO, 1977, ROUSSEAU *et al.*, 1988). It was shown that caffeine sensitizes RyRs to cytosolic  $\text{Ca}^{2+}$  at low concentrations (<1 mM), while higher doses (>2.5 mM) increase the sensitivity of RyRs to luminal  $\text{Ca}^{2+}$  (LEE, 1993, PORTA *et al.*, 2011).

The ability of cyclic ADP-ribose (cADPR, **Fig. 1.4, B**), a metabolite of  $\text{NAD}^+$ , to stimulate  $\text{Ca}^{2+}$  release via RyRs in sea urchin egg microsomes has been reported (GALIONE, 1993, GALIONE, 1994). These reports could be further extended to smooth muscle cells (MURTHY *et al.*, 1995, PRAKASH *et al.*, 1998) and finally, to Jurkat T cells (GUSE *et al.*, 1997). It has been demonstrated that

## Introduction

cADPR can induce  $\text{Ca}^{2+}$  signaling independently from  $\text{IP}_3$  (DARGIE *et al.*, 1990), and acting instead via the potentiation of CICR (GALIONE *et al.*, 1991, LEE, 1993). The mechanism of cADPR is similar to that of caffeine, however, it shows higher potency in sensitization of RyRs to  $\text{Ca}^{2+}$ . It has been suggested that interplay between cADPR and calmodulin as an accessory protein is essential for RyR activation in sea urchin eggs (LEE *et al.*, 1994, LEE *et al.*, 1995, TANAKA and TASHJIAN, 1995). There, cADPR induces a short, but rapid  $\text{Ca}^{2+}$  release, which is sustained by calmodulin. By means of single-particle electron cryomicroscopy, a calmodulin-like domain within the core of mammalian RyR1 was identified as a calcium sensor (ZALK *et al.*, 2015), thereby confirming previous results suggesting calmodulin directly interacting with RyR1 (XIONG *et al.*, 2006).

**Fig. 1.4** | Skeletal formulas of selected RyR agonists that initiate RyR mediated  $\text{Ca}^{2+}$  release. (A) Caffeine. (B) cADPR. (C) NAADP.

Such as cADPR, NAADP (Fig. 1.4, C) is a metabolite of  $\text{NAD}^+$ . It was long assumed that NAADP—in contrast to cADPR and  $\text{IP}_3$ —mobilizes  $\text{Ca}^{2+}$  from separable stores (LEE and AARHUS, 1995), namely acidic lysosomes (CHURCHILL *et al.*, 2002). However, it was demonstrated that NAADP is a potent mobilizer for  $\text{Ca}^{2+}$  in Jurkat T cells (BERG *et al.*, 2000) and mediates T cell activation by high-affinity binding to RyRs (LANGHORST *et al.*, 2004, DAMMERMANN and GUSE, 2005). Furthermore, it could be shown in both—Jurkat T cells as well as in primary myelin basic protein (MBP)-reactive rat

## Introduction

T cells—that NAADP signaling to RyR1 could be successfully suppressed by BZ194, a synthetic NAADP antagonist (DAMMERMANN *et al.*, 2009), showing that NAADP is an effective agonist for RyR1. Thereby the antagonizing effect of BZ194 was exclusively affecting the NAADP signaling pathway, but not cADPR or IP<sub>3</sub> mediated Ca<sup>2+</sup> signaling (DAMMERMANN *et al.*, 2009). Preventive or therapeutic treatment of Lewis rats with BZ194 significantly ameliorated the course of EAE but did not affect primary immune responses (CORDIGLIERI *et al.*, 2010). Accordingly, NAADP signaling is essential for the activation of auto-aggressive T cells.

### 1.9 Objectives of this study

RyRs are a family of Ca<sup>2+</sup> channels that mediate Ca<sup>2+</sup> release from intracellular stores upon activation by secondary messengers, such as NAADP or cADPR. In non-excitabile cells, the depletion of Ca<sup>2+</sup> stores in response to external stimuli evokes further Ca<sup>2+</sup> entry across the plasma membrane, thereby activating Ca<sup>2+</sup> sensitive signaling pathways. For example, the increase of intracellular Ca<sup>2+</sup> in T cells represents an initial trigger for TCR dependent T cell activation.

T cells play a pivotal role in autoimmune diseases of the CNS like MS and its animal model EAE. The understanding of intrinsic factors that control the activation of (auto-aggressive) T cells is indispensable for the development of new therapies. In this context, the role of RyRs has been poorly investigated. However, recent studies suggested RyRs as a therapeutic target in T cell mediated autoimmune diseases.

Using Ryr1 and Ryr3 knockout mice, we aim to address following point:

1. Analysis of a steady state immune system in mice with ablation of the RyR1 and RyR3 genes.
2. Effect of RyR1 or RyR3 deletion on the clinical outcome and CNS pathology of active EAE.
3. Determination of mechanisms that mediate RyR1 and RyR3 contribution to the autoimmune neuroinflammatory disease.

## 2 Materials and Methods

### 2.1 Buffers and Media

All solutions were prepared in Milli-Q purified water (MERCK MILLIPORE, Schwalbach, Germany) and sterilized by autoclaving and / or filtration before use. If not declared otherwise, all chemicals were purchased from CARL ROTH (Karlsruhe, Germany) or SIGMA-ALDRICH (Munich, Germany).

#### **Ammonium-Chloride-Potassium (ACK) erythrolysis buffer**

0.15 M  $\text{NH}_4\text{Cl}$ , 10 mM  $\text{KHCO}_3$ , 0.1 mM  $\text{EDTA}\cdot 2\text{Na}$  in  $\text{H}_2\text{O}$ , pH 7.2–7.4.

#### **Dulbeccos's Modified Eagle Medium (DMEM)**

133.8 g Gibco® DMEM powder (LIFE TECHNOLOGIES, Carlsbad, California, USA) in 10 L  $\text{H}_2\text{O}$ , supplemented with 37 g acetic acid ( $\text{CH}_3\text{COOH}$ ).

#### **Eagle's HEPES (EH) medium**

133.8 g Gibco® DMEM powder (LIFE TECHNOLOGIES, Carlsbad, California, USA) in 10 L  $\text{H}_2\text{O}$ , supplemented with 37 g  $\text{CH}_3\text{COOH}$  and 25 mM HEPES (LIFE TECHNOLOGIES).

#### **FACS buffer**

1×PBS supplemented with 0.5 % BSA and 0.05 %  $\text{NaN}_3$ .

#### **Glial cell medium (GCM)**

GCM was prepared by supplementing DMEM with 15 % FCS (BIOCHROM AG, Berlin, Germany), 1 % Gibco® minimum essential medium non-essential amino acids (MEM NEAA, 100x, LIFE TECHNOLOGIES), 1 % Gibco® penicillin/streptomycin (10,000 units/ml penicillin, 10,000  $\mu\text{g}/\text{ml}$  streptomycin, LIFE TECHNOLOGIES), 1 mM Gibco® sodium pyruvate (LIFE TECHNOLOGIES), 2 mM L-glutamine (PAN-BIOTECH, Aidenbach, Germany), 1 mM L-asparagine monohydrate and 0.4 % 2-mercaptoethanol (13.6 M).

## *Materials and Methods*

### **L929 fibroblast-conditioned medium (LCCM)**

L929 cells were plated in a 10 cm petri dish (SARSTEDT, Nümbrecht, Germany) with DMEM supplemented with 10 % FCS and 1 % Gibco® penicillin/streptomycin, 1 mM Gibco® sodium pyruvate and 2 mM L-glutamine. Confluent cells were splitted into 175 cm<sup>2</sup> flasks. After reaching confluence, the supernatant was collected and passed through a 0.22 µm filter. The obtained medium was stored as 5×LCCM.

### **Percoll, isotonic Percoll and underlay Percoll solutions**

Percoll® (GE HEALTHCARE, Chalfont St. Giles, UK) density centrifugation medium was diluted 1:10 with 10×PBS to produce isotonic Percoll. Underlay Percoll was composed of 70 % isotonic Percoll in 1×PBS.

### **Phosphate buffered saline (PBS)**

137 mM NaCl, 2.7 mM KCl, 10 mM Na<sub>2</sub>HPO<sub>4</sub> and 1.8 mM KH<sub>2</sub>PO<sub>4</sub> in H<sub>2</sub>O, pH 7.4. Ten times the amount of NaCl, KCl, Na<sub>2</sub>HPO<sub>4</sub> and KH<sub>2</sub>PO<sub>4</sub> was used to produce 10×PBS.

### **Proteinase K buffer**

100 mM Tris·HCl, 200 mM NaCl, 0.2 % SDS and 5 mM EDTA in H<sub>2</sub>O, pH 8.0. Fresh Proteinase K (10 mg/ml) was added directly before use to a final concentration of 1 %.

### **Roswell Park Memorial Institute medium 1640 (RPMI 1640)**

104.3 g Gibco® RPMI 1640 powder (LIFE TECHNOLOGIES) in 10 L H<sub>2</sub>O, supplemented with 22 g NaHCO<sub>3</sub>.

### **Restimulation medium (ReMed)**

ReMed was prepared by supplementing RPMI 1640 with 5 % FCS, 1 % Gibco® minimum essential medium non-essential amino acids (MEM NEAA, 100×, LIFE TECHNOLOGIES), 1 % Gibco® penicillin/streptomycin (10,000 units/ml penicillin, 10,000 µg/ml streptomycin, LIFE TECHNOLOGIES), 1 mM Gibco® sodium pyruvate (LIFE TECHNOLOGIES), 2 mM L-glutamine (PAN-BIOTECH, Aidenbach, Germany) and 0.4 % 2-mercaptoethanol (13.6 M).

### **Tris/Borate/EDTA (TBE) buffer, 10×**

1 M Tris, 0.9 M boric acid and 0.01 M EDTA in 1 L H<sub>2</sub>O.

## 2.2 Molecular Procedures

### 2.2.1 Genotyping by polymerase chain reaction (PCR)

Genomic DNA (gDNA) was obtained by isopropyl alcohol precipitation after digestion of tissue or cells with Proteinase K (2–16 h, 56 °C, dry block thermostat TDB-100, BIOSAN). DNA fragments were amplified by PCR using the DreamTaq Polymerase Mix (THERMO FISCHER SCIENTIFIC INC., Waltham, Massachusetts, USA) and target specific primer pairs (BIOMERS, Ulm, Germany). Amplification programs were specific for each set of primers (Mastercycler ep gradient, EPPENDORF, Hamburg, Germany).

PCR products were loaded on 0.8–1.5 % TBE agarose gels and electrophoresed at 100 V for 30–60 min before visualization with an E-BOX VX5 gel documentation system and the corresponding VisionCapt 15.0 software (VILBER LOURMAT, Eberhardzell, Germany).

### 2.2.2 RNA extraction and cDNA synthesis

The RNeasy Kit (QIAGEN, Hilden, Germany) was used to isolate RNA from either organs, tissues or cells. Obtained RNA was transcribed into cDNA using random hexamer primers (FirstStrand cDNA Synthesis Kit, THERMO FISCHER SCIENTIFIC INC.) according to the manufacturer’s instructions. cDNA was either stored at –20 °C or subsequently used as template for quantitative real-time PCR.

### 2.2.3 Quantitative real-time polymerase chain reaction

Gene expression was assessed by (semi-) quantitative real-time PCR (qPCR) using the StepOnePlus™ Real-Time PCR System (APPLIED BIOSYSTEMS, Darmstadt, Germany) and the corresponding StepOne Software v2.0. The qPCR was performed with gene-specific TaqMan® probes labeled with 6-FAM™ and quenched by TAMRA™.  $\beta$ -actin was used as the housekeeping gene. Individually designed primers and probes were ordered from SIGMA-

## Materials and Methods

ALDRICH. Before applied in qPCR, cDNA samples were diluted 1:50. Data from samples were obtained in duplicates.

## 2.3 Cell Culture Procedures

If not declared otherwise, cells were incubated at 37 °C in a humidified 5 % CO<sub>2</sub> atmosphere.

### 2.3.1 Preparation of cell suspensions from organs

Single cell suspensions of lymph nodes and spleen were prepared by smashing the organs through a metal mesh (UNIVERSITÄTSMEDIZIN GÖTTINGEN, in-house production) using a pistil (B. BRAUN MELSUNGEN AG, Melsungen, Germany). The obtained homogenizate was centrifuged (4 °C, 1200 rpm, 5 min) and resuspended in EH medium.

### 2.3.2 Erythrolysis

Erythrocytes residing in spleen or blood were depleted by resuspension of spleen homogenates or blood samples in ACK buffer and further incubation for 5 min on ice. Then, the cells were washed once in PBS and resuspended in EH medium.

### 2.3.3 Lymphocyte isolation from blood

Blood was either collected from the tail vein (living animals) or by cardiac puncture (dead animals) in 80 mM EDTA/PBS. Lymphocytes were separated from whole blood by the use of lymphocyte separation medium 1077 (LSM 1077, GE HEALTHCARE, Chalfont St. Giles, UK) and centrifugation at 2000 rpm for 20 min at 4 °C with minimal acceleration and brakes. Lymphocytes accumulated at the interphase and were collected in FACS buffer.

### 2.3.4 Lymphocyte isolation from CNS

Lymphocytes were isolated from spinal cord or brain by Percoll density gradient centrifugation. The CNS tissue was minced into a fine slurry, taken up in 25 ml EH medium and then mixed with 10 ml of isotonic Percoll. 10 ml of underlay Percoll medium was pipetted gently under the cell suspension prior to centrifugation (20 °C, 30 min, 2780 rpm) with minimal acceleration and brakes.

### 2.3.5 Isolation and enrichment of T and B cells

Single cell suspensions of lymph nodes or spleen were prepared as described. For the isolation, a concentration of  $1 \times 10^8$  cells/ml was achieved in

recommended resuspension medium. CD3<sup>+</sup> T cells, naïve T cells and B cells were isolated using the EasySep™ Enrichment Kits for murine CD3<sup>+</sup> T cells, naïve CD4<sup>+</sup> T cells and B cells (each STEMCELL TECHNOLOGIES, Vancouver, British Columbia, Canada) according to the manufacturer's instructions for "The Big Easy" EasySep™ Magnet. In brief, biotinylated antibodies directed against non-wanted cell populations and tetrameric antibody complexes against biotin conjugated with dextran-coated magnetic particles were applied to the single cell suspension to mark cells for magnetic forced removal. After enrichment, the cell purity was determined by flow cytometry and was usually ≥90 %.

### **2.3.6 Isolation of astrocytes via MACS® purification**

Astrocytes from spinal cord were isolated using the MACS® anti-GLAST MicroBead Kit (MILTENYI BIOTECH GMBH, Bergisch Gladbach, Germany).

### **2.3.7 Generation of primary astrocytes and microglia**

Cell cultures of primary astrocytes and microglia were generated as described (CHEN *et al.*, 2012). In brief, neonatal mice (age 0–2 days) were killed by decapitation. The skin over the skull was flayed before opening the skull itself to access the brain. The brain was then placed on ice and the meninges were removed using a Stemi 2000 stereo microscope (CARL ZEISS, Jena, Germany). The cleaned brain was minced into a fine slurry and afterward digested with trypsin/EDTA for 15–30 min in a 37 °C incubator. The suspension was passed through a Falcon® 40 µm cell strainer (CORNING, INC., Corning, New York, USA), centrifuged (4 °C, 1200 rpm, 5 min), resuspended in glial cell medium (GCM) and added to poly-D-lysine coated tissue culture flasks (TPP TECHNO PLASTIC PRODUCTS AG, Trasadingen, Switzerland). The cells were incubated at 37 °C in a humidified 5 % CO<sub>2</sub> atmosphere for 24 h before adding LCCM. After 10–14 days the microglial cells were detached by using a heated orbital shaker (INKUTEC GMBH, Kiebitzhörn, Germany) at 240 rpm for 2 h. Both microglia and remaining plate-bound astrocytes could be further cultured in GCM at 37 °C in a humidified 5 % incubator. Cell purity was assessed by immunocytochemistry.

### **2.3.8 Cell counting**

To determine the cell number within a certain volume, 10 µl of a given cell suspension were loaded on a Neubauer improved hemocytometer (LO LABOROPTIK LTD, Lancing, UK). Trypan blue (0.04 %) was added to the suspension to distinguish between viable and non-viable cells. The cell number was calculated with the use of the following equation:

$$\frac{\text{Counted Cells}}{\text{Number of Quadrants}} \times \text{Dilution Factor} \times 10^4 = \text{Cells / ml}$$

## 2.4 Animal Experiments

### 2.4.1 Mice

All animal experiments were carried out in the central animal facility of the University Clinical School Göttingen in accordance with the regulations for animal welfare of Lower Saxony, Germany. All mouse strains were kept in individually ventilated cages under specific-pathogen-free conditions in a normal 12 h day-night cycle and fed *ad libitum*. Experiments were performed with at least 10 weeks old mice. The following C57BL/6 strains were used: Wildtype (WT, CHARLES RIVER LABORATORIES, Wilmington, Massachusetts, USA), WT, CD45.1 congenic (CHARLES RIVER LABORATORIES), TCR<sup>MOG</sup> (2D2, BETELLI *et al.*, 2003), IgH<sup>MOG</sup> (Th, LITZENBURGER *et al.*, 1998), OT II (BARNDEN *et al.*, 1998), Rosa26-tdRFP (LUCHE *et al.*, 2007), *Ryr1*<sup>+/-</sup> (TAKESHIMA *et al.*, 1994), *Ryr3*<sup>-/-</sup> (TAKESHIMA *et al.*, 1996). We crossed these strains to generate the following mutants that were used for this study: *Ryr1*<sup>+/-</sup>×RFP, *Ryr3*<sup>-/-</sup>×RFP, *Ryr1*<sup>+/-</sup>×*Ryr3*<sup>-/-</sup>×RFP, *Ryr3*<sup>-/-</sup>×2D2×RFP, *Ryr3*<sup>-/-</sup>×2D2×IgH<sup>MOG</sup>×RFP, *Ryr3*<sup>-/-</sup>×OT II×RFP.

### 2.4.2 Generation of fetal liver and bone marrow chimeric mice

In brief, pregnant female donor mice were euthanized at gestation day 14. The individual embryos were removed aseptically and fetal livers were isolated. A single-cell suspension was made by passing the liver through a 1 ml pipette tip. After centrifugation the cells were resuspended in StemSpan<sup>TM</sup> medium supplemented with 20 ng/ml SCF, 20 ng/ml IL-3 and 50 ng/ml IL-6 (STEMCELL TECHNOLOGIES SARL, Cologne, Germany) and cultivated for 3–4 h. About  $5 \times 10^6$  cells were intravenously injected into lethally irradiated mice (C57Bl/6: 12.5 Gy). Recipient animals were maintained on neomycin trisulfate (2 mg/ml) containing drinking water for 4 weeks to prevent infections.

To generate bone marrow chimeric mice, donor mice were euthanized and the femur and tibia were collected. After removing excess flesh and the ends of the bone the bone marrow was flushed out using a 27-gauge needle. After erythrolysis, cells were counted and about  $7 \times 10^6$  cells were injected into lethally irradiated mice (C57Bl/6: 12.5 Gy). Recipient animals were maintained on neomycin trisulfate (2 mg/ml) containing drinking water for 4 weeks to prevent infections.

After 4 weeks, peripheral blood was collected to screen recipient mice for successful reconstitution by immunostaining (TCR- $\beta$  and B220 antibodies) and flow cytometry.

### **2.4.3 MOG<sub>35-55</sub> EAE induction by active immunization and disease evaluation**

Mice were anesthetized by injection of ketamine (80 mg/kg, MEDISTAR, Ascheberg, Germany) and xylazine (8 mg/ml, ECUPHAR, Greifswald, Germany). EAE was then induced by immunization with the 2D2 TCR epitope MOG<sub>35-55</sub> (MEVGWYRSPFSRVVHLYRNGK, purchased from the Institute for Medical Immunology, CHARITÉ UNIVERSITÄTSMEDIZIN BERLIN, Germany) in at least 10 weeks old mice. Antigen emulsion containing 50 µg complete Freund's adjuvant (incomplete Freund's adjuvant (Difco™, BECTON DICKINSON, Franklin Lakes, New York, USA, supplemented with *Mycobacterium tuberculosis* H37Ra (Difco™, BECTON DICKINSON)) and 50 µg MOG<sub>35-55</sub> was injected subcutaneously at the base of the tail. Pertussis toxin (LIST BIOLOGICAL LABORATORIES, Campbell, California, USA) was injected intraperitoneal on the day of immunization and 48 h later (except fetal liver and bone marrow chimeras). The mice were weighed and examined for clinical signs of EAE daily, starting on day 7 after immunization. EAE was assessed according to the following scoring system:

Score 0: healthy; no motor deficits and full tail tone;

Score 1: reduced tail tone;

Score 2: flaccid tail paralysis;

Score 3: absent body righting when walking;

Score 4: gait ataxia;

Score 5: mild paralysis of hind limbs;

Score 6: paralysis of one hind limb or moderate hind limb paraparesis;

Score 7: severe paraparesis or paraplegia;

Score 8: tetraparesis;

Score 9: moribund state;

Score 10: dead.

Mice with a score of  $\geq 5$  were provided with easier access to food and water. For ethical reasons, mice with a score  $\geq 7$  were sacrificed.

### **2.4.4 Dantrolene injections**

Dantrolene sodium salt was solved in 10 % DMSO in PBS and was injected daily intraperitoneally at a concentration of 20 mg/kg body weight.

### **2.4.5 Euthanasia**

Mice were asphyxiated with carbon dioxide (CO<sub>2</sub>) gas.

## 2.5 Experimental Procedures

### 2.5.1 Staining of cell surface markers

Surface proteins were stained with fluorescently labeled antibodies.  $1 \times 10^6$  cells were resuspended in 200  $\mu$ l FACS buffer containing the respective antibodies and incubated in the dark at 4 °C for 30 min. Cells were centrifuged at 4 °C at 1200 rpm for 5 min before transfer into 5 ml FACS tubes (BD BIOSCIENCES, Franklin Lakes, New Jersey, USA) in a volume of 200  $\mu$ l FACS buffer.

### 2.5.2 Flow cytometry

FACS analysis was performed using the flow cytometer FACSCalibur™ (BD Biosciences), that consists of an air-cooled argon laser ( $\lambda_{\text{ex}}=488$  nm) and a red diode laser ( $\lambda_{\text{ex}}=640$  nm), enabling the measurement of four different fluorescent parameters (channels).

With a flow cytometer the cell number in a given sample could be quantified using Calibrite APC beads (BD BIOSCIENCES). A certain number of beads was resuspended in PBS and 50  $\mu$ l of the suspension was added to 200  $\mu$ l cell suspension. The total cell number was calculated as follows:

$$\left( \frac{\text{Beads}/50 \mu\text{l} \times \text{Acquired Cells}}{\text{Acquired Beads}} \right) \times \text{Dilution Factor} = \text{Cell Count}$$

### 2.5.3 CFSE dilution assay

Isolated, antigen-specific T cells were labeled with carboxyfluorescein diacetate succinimidyl ester (CFSE). In brief,  $2 \times 10^6$  T cells were incubated in the presence of 0.25  $\mu$ M CFSE for 10 min at 37 °C. The CFSE labeled cells were then injected i.v. into host animals. 48 h hours after transfer the mice were immunized with MOG<sub>35-55</sub>. T cell proliferation in draining lymph nodes, non-draining lymph nodes and spleen was determined 48 h, 60 h, 72 h and 96 h after immunization by measuring the dilution of CFSE occurring with every cell division using flow cytometry.

### 2.5.4 Transwell migration assay

T cells were activated *in vivo* by immunization of mice against MOG<sub>35-55</sub> peptide. On day 9 after immunization, lymph nodes, spleen and blood samples were taken and T cells were isolated by negative selection. The cells were then labeled with 0.25  $\mu$ M CFSE and placed on the upper layer of the cell permeable membrane (pore size 5.0  $\mu$ m) of the migration chamber (Boyden multiwell chamber, CORNING INC., New York, USA), allowing them to migrate towards the lower chamber which contains the testing solution. The quantity of migrated cells was assessed by FACS after 5 h of incubation.

### 2.5.5 Glutamate release detection assay

The concentration of free glutamate in astrocyte culture supernatants was assessed by using the Glutamate Colorimetric Assay Kit (BIOVISION, INC., Milpitas, California, USA) according to the manufacturer's instructions. Confluent grown cultures of astrocytes were stimulated as indicated. Supernatants were collected 10 min, 2 h and 16 h after stimulation and were diluted 1:10 before use.

### 2.5.6 Thymidine incorporation assay

Lymphocytes, splenocytes or enriched T cells ( $3 \times 10^5$ /well, in triplicates) were stimulated with indicated concentrations of anti-CD3 and/or anti-CD28 antibodies, or MOG<sub>35-55</sub> peptide in ReMed (37 °C, 5 % CO<sub>2</sub>). After 24 h of stimulation, tritiated thymidine (<sup>3</sup>H]dT, 2 Ci/mmol, GE HEALTHCARE) was added to the culture. Radioactivity was measured 16 h later using a MicroBeta Trilux 1450LSC β counter (PERKINELMER, Waltham, Massachusetts, USA).

CD3	Rat	145-2C11	BIOLEGEND
CD28	Rat	37.51	BIOLEGEND

## 2.6 Immunocytochemistry

### 2.6.1 Cytospin and staining of suspension cells

For fluorescent stainings of non-adhering cells,  $5-10 \times 10^4$  cells were gently spun down (1000 rpm, 7 min, medium acceleration and brakes, RT) on Superfrost™ Plus microscope slides using a Cytospin® 4 cytocentrifuge (THERMO FISCHER SCIENTIFIC INC.). The cells were then first fixed with 4 % PFA for 15 min before blocking in 10 % FCS / 0.02 % Triton X-100 in PBS for 30 min at RT in a humidified chamber to prevent drying of cells. Then, primary antibodies were applied O/N at 4 °C in blocking buffer. After washing with PBS, secondary antibodies were applied for 60 min at RT. Afterward, nucleic acids were stained with DAPI (5 min, RT) to visualize cell nuclei. The samples were mounted with one drop of Fluoromount-G™ (SOUTHERNBIOTECH, Birmingham, Alabama, USA) and sealed with a coverslip. The slides were then directly used for microscopy or stored in the dark at 4 °C.

### 2.6.2 Staining of adherent cells

To stain adherent cells like astrocytes and microglia, the cells were detached by trypsinization and seeded on cleaned coverslips in a 6-well or 12-well plate. After 24 h, the cells were fixed with 4 % PFA for 15 min before blocking in 10 % FCS / 0.02 % Triton X-100 in PBS for 30 min at RT. Then the coverslips were taken out and further processed upside down on Parafilm

## Materials and Methods

slices (BEMIS COMPANY, INC., Neenah, Wisconsin, USA) to allow lower incubation volumes for the antibody solutions. After incubation with primary and secondary antibodies and DAPI (as described in chapter 2.6.1), the coverslips were mounted with one drop of Fluoromount-G™ and placed upside down on a microscope slide before microscopy or storage.

### 2.6.3 Image acquisition

Fluorescent images were acquired using the Zeiss Axio Observer.Z1 microscope equipped with a Zeiss Plan Achromat 20× or 40× lens (both CARL ZEISS, Jena, Germany) and a HXP 120C metal halide lamp (LEISTUNGSELEKTRONIK JENA GMBH, Jena, Germany) as a light source. Fluorescent emission was detected using a Zeiss AxioCam HSm (CARL ZEISS). Excitation ( $\lambda_{ex}$ ) and emission ( $\lambda_{em}$ ) wavelengths were as followed: GFP, FITC,  $\lambda_{ex}=470$  nm,  $\lambda_{em}=509$  nm; RFP, AF594,  $\lambda_{ex}=558$  nm;  $\lambda_{em}=583$  nm; DAPI,  $\lambda_{ex}=350$  nm;  $\lambda_{em}=470$  nm. Images were processed by using the Zeiss AxioVision v4.8 software (CARL ZEISS).

## 2.7 Histology and Immunohistochemistry

### 2.7.1 Perfusion

After euthanasia, the thorax was opened to access the heart. The mice were first perfused with PBS through the left ventricle for 10 min and a small incision was made into the right atrium to allow efflux of the blood. The mice were then perfused for another 10 min with 4 % PFA to allow fixation of tissues. After perfusion, organs of interest were stored in 4 % PFA for at least another 48 h at 4 °C before further processing.

### 2.7.2 Dehydration and paraffin embedding of fixed tissues

PFA-fixed organs were washed with PBS and sliced into appropriate pieces before inserting them into tissue cassettes (TESPA, Gießen, Germany). The samples were then dehydrated (70 % EtOH, 1 change, 60 min; 80 % EtOH, 1 change, 60 min; 90 % EtOH, 2 changes, 60 min each; 95 % EtOH, 2 changes, 90 min each; 100 % EtOH, 2 changes, 90 min each; xylene, 2 changes, 60 min each; paraffin wax, 56–58 °C, 120 min each) with an automatic tissue processor TP1020 (LEICA BIOSYSTEMS, Wetzlar, Germany). Following dehydration, tissues were embedded into paraffin blocks with a Leica EG1160 embedding machine.

### 2.7.3 Preparation of embedded samples for tissue stains

The tissue containing paraffin blocks were cut into 3 µm thick slices with a Leica SM2000R microtome, taken up on microscope slides and dried at 37 °C O/N. Prior to further processing, samples were rehydrated (xylene, 2 changes, 15 min each; 100 % EtOH, 2 changes, 2 min each; 96 % EtOH, 2 changes, 2 min each; 70 % EtOH, 2 changes, 2 min each; distilled water, 2 changes, 2 min).

### 2.7.4 Hemalum & eosine (HE) stain

Rehydrated samples were stained with filtered Mayer's hemalum solution (MERCK, Darmstadt, Germany) for 10 min to visualize nuclei, followed by 10 min extensive washing with non-distilled water. To stain the cytoplasm, the samples were exposed to 0.1 % eosine Y solution (MERCK, diluted with acetic acid) for 2 min. After washing, the samples were again dehydrated (70 % EtOH, 2 changes, 2 min each; 96 % EtOH, 2 changes, 2 min each; 100 % EtOH, 2 changes, 2 min each; xylene, 2 changes, 15 min each), mounted with Entellan™ and sealed with a coverslip.

### **2.7.5 Luxol fast blue-Periodic acid-Schiff stain**

The samples were rehydrated incompletely (stop after 96 % EtOH) and incubated O/N at 56 °C in 0.1 % LFB solution (ABCR GMBH & CO. KG, Karlsruhe, Germany, diluted with 96 % EtOH / 0.05 % acetic acid). Then they were washed in 96 % EtOH and incubated in 0.1 % lithium carbonate ( $\text{Li}_2\text{CO}_3$ ) for 30 sec. The samples were washed very briefly in 70 % EtOH and distilled water before incubation for 10 min in 0.8 % periodic acid ( $\text{H}_5\text{IO}_6$ ) to wash off excess  $\text{Li}_2\text{CO}_3$ . After washing with distilled water, the specimens were incubated in Schiff reagent for 20 min. Excess reagent was washed off with sulfite washing solution (0.1 % of concentrated (37 %) HCl, 4 % potassium metabisulfite ( $\text{K}_2\text{S}_2\text{O}_5$ ) in  $\text{H}_2\text{O}$ ). Prior final dehydration and embedding, the samples were washed extensively in non-distilled water for 10 min.

### **2.7.6 Bielschowsky's silver stain for axons**

Prior to further processing, samples were completely rehydrated. Next, the samples were incubated for 15 min at 37 °C in preheated silver nitrate ( $\text{AgNO}_3$ ) and were washed afterward in distilled water. During this washing step, ammonia ( $\text{NH}_3$ ) is given to the previously used  $\text{AgNO}_3$  solution to prepare silver hydroxide ( $\text{AgOH}$ ). The specimens were then incubated in this solution for 10 min at 37 °C in the dark. Afterward, samples were washed twice in 0.1 %  $\text{NH}_3$ . To the used  $\text{AgOH}$ , 11–15 drops of developer solution (5.4 ml 37 % formaldehyde in 114.6 ml  $\text{H}_2\text{O}$  + 1 drop of 65 % nitric acid ( $\text{HNO}_3$ ) + 0.5 g citric acid) were added. In this solution, the samples were incubated for 4–10 min under gentle shaking. The specimens were washed briefly in 0.1 %  $\text{NH}_3$  and distilled water before final dehydration and embedding. The slides were stored at 4 °C in the dark.

### **2.7.7 Antibody stains**

Specimens were completely rehydrated as described before boiling in 0.1 M citric acid (pH 6.0) for 20 min in a microwave oven at 600 W. After cooling down to RT, the samples were washed in distilled water and PBS (2 min, 4 changes each) followed by incubation in 3 % hydrogen peroxide ( $\text{H}_2\text{O}_2$ ) in PBS for 10 min. The binding sites were then blocked by incubation in 10 % FCS / 0.02 % Triton X-100 in PBS for 10 min. Primary antibodies were applied in blocking buffer O/N at 4 °C. After washing with PBS, secondary, biotinylated antibodies were applied at RT for 60 min. After additional washing, a streptavidin-peroxidase complex (ExtrAvidin®-Peroxidase, SIGMA-ALDRICH) was applied to the specimens (incubation at RT, 60 min). Diaminobenzidine (DAB, 2g dissolved in 80 ml PBS) was used as a substrate for oxidation which results in a dark-brown color (10 min incubation, RT). By that, the antibody labeled proteins could be visualized. The specimens were counterstained with Mayer's hemalum solution to visualize cell nuclei. Afterward, the samples were dehydrated, embedded and stored at RT.

**Table 2.6 | Primary antibodies used in immunohistochemistry**

### 2.7.8 Image acquisition

Pictures were taken with an Olympus BX51 microscope equipped with an UPlan FL N 10× or 20× lens and processed with analySIS<sup>B</sup> imaging software (each OLYMPUS, Shinjuku, Tokyo, Japan).

## 2.8 Imaging of Subcellular Calcium Signals

### 2.8.1 Preparation of cells for calcium signal measurements

Astrocytes were seeded on a chambered microscope slide ( $\mu$ -Slide 8 Well, IBIDI GMBH, Planegg / Martinsried, Germany) in a concentration of  $5-10 \times 10^4$  cells per well. The cells were incubated with membrane permeable AM esters of  $\text{Ca}^{2+}$  dyes Fluo-4 and Fura-2 (10  $\mu\text{M}$  each) in 0.04 % Pluronic F-127 (SIGMA-ALDRICH) for 30 min at 37 °C in the dark. Next, the cells were washed once with  $\text{Ca}^{2+}$  buffer (140 mM NaCl, 5 mM KCl, 1 mM  $\text{MgSO}_4$ , 1 mM  $\text{CaCl}_2$ , 20 mM HEPES, 1 mM  $\text{NaH}_2\text{PO}_4$ , 5 mM glucose, pH 7.4) before further incubation in  $\text{Ca}^{2+}$  buffer for 20 min at RT in the dark for de-esterification. All substances for stimulation were applied in  $\text{Ca}^{2+}$  buffer.

### 2.8.2 Image acquisition and processing

An DM IRBE microscope (LEICA MICROSYSTEMS, Wetzlar, Germany) with 100× magnification was used in combination with a DG-4 light source

## Materials and Methods

(SUTTER INSTRUMENTS, Novato, California, USA). Images were acquired every 5 sec over a total time of 20 min using an EM-CCD C9100 camera (HAMAMATSU PHOTONICS, Hamamatsu, Japan) with a resolution of 512×512 pixels (14-bit color depth; 2× binning) and a DualView module (PERKINELMER, INC.). The following filter set (AHF ANALYSENTECHNIK, Tübingen, Germany) was used for acquisition: Excitation  $\lambda=480/40$  nm; beamsplitter  $\lambda=495$  nm; emission1  $\lambda=542/50$  nm; emission2  $\lambda=650/57$  nm). Acquisition was performed using the Volocity v6.6.2 software (PERKINELMER, INC.).

### 2.8.3 Data evaluation

Image processing using the Fiji v1.47 software (GPL v2) allowed splitting of frames acquired with the DualView module into the two wavelength channels for post-measurements and calculation of the Fura-2 / Fluo-4 emission wavelength ratio (using Openlab software v5.5.2, PERKINELMER, INC.) as described (KUNERTH *et al.*, 2003; WOLF *et al.*, 2015, manuscript in revision).

## 2.9 Statistics

If not declared otherwise, data are always depicted as mean + standard error of the mean (SEM). Methods for statistical evaluation were indicated in each figure and annotated with the following p-values: ns  $P \geq 0.05$ , \* $P \leq 0.05$ , \*\* $P \leq 0.01$  and \*\*\* $P \leq 0.001$ .

## 3 Results

### 3.1 RyR1 and RyR3 in immune cells

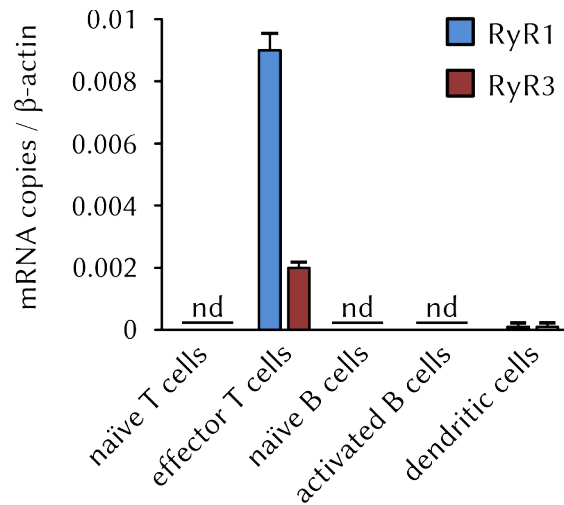

The elevation of intracellular free  $\text{Ca}^{2+}$  ( $[\text{Ca}^{2+}]_i$ ) provides a major signal for T cell activation upon antigen recognition. Within the cell, the endoplasmic reticulum (ER) is the main storage compartment for free calcium, whose release into the cytosol is mediated by two types of calcium channels— $\text{IP}_3$  receptors and ryanodine receptors (RyRs)—upon activation by second messengers. It has been suggested recently that RyRs constitute a potential target for the second messenger NAADP in Jurkat and Lewis rat T cells (DAMMERMANN *et al.*, 2009). It was demonstrated that pharmacological antagonism of NAADP strongly reduced RyR mediated intracellular  $\text{Ca}^{2+}$  signals in Jurkat T cells and rat  $\text{T}_{\text{MBP}}$  cells. Furthermore, effector  $\text{T}_{\text{MBP}}$  cells were more susceptible to NAADP antagonism than naïve or memory T cells, and expression of the RyR isoforms RyR1 and RyR3 was up-regulated in effector T cells. The impact of NAADP antagonism on  $\text{Ca}^{2+}$  signaling was supported by the finding that antagonizing NAADP during Lewis rat EAE significantly ameliorated the course of the disease (DAMMERMANN *et al.*, 2009).

For this study, *Ryr* knockout mice were used to investigate the role of RyRs in the murine immune system and to evaluate the NAADP–RyR signaling pathway as a potential target for treatment of autoimmune diseases of the CNS.

#### 3.1.1 *Ryr1* and *Ryr3* mRNA is expressed in effector T cells

Multiple sclerosis (MS) and its animal model experimental autoimmune encephalomyelitis (EAE) are described as T cell mediated inflammatory diseases (MILLER *et al.*, 2007). As part of EAE pathology, T cells recruit other leukocyte populations like B cells and macrophages into the CNS, thereby sustaining the disease and damaging the CNS (PIERSON *et al.*, 2013). In order to investigate the function of RyRs in T cells and EAE, the expression of *Ryr1* and *Ryr3* mRNA in immune cells of WT C57BL/6 mice was determined by means of qRT-PCR. Therefore, naïve T cells ( $\text{CD4}^+\text{CD62L}^{\text{high}}\text{CD44}^{\text{low}}$ ), effector T cells ( $\text{CD4}^+\text{CD62L}^{\text{low}}\text{CD44}^{\text{high}}$ ), naïve B cells ( $\text{B220}^+\text{CD19}^+$ ), activated B cells, and dendritic cells (DCs;  $\text{CD11c}^+$ ) were analyzed (**Fig. 3.1**). Consistent with previous studies, *Ryr1* and *Ryr3* mRNA was not detectable in naïve T cells, but present in effector T cells. No expression of *Ryr1* and *Ryr3* mRNA were found either in naïve or activated B cells. In DCs, only minimal amounts of *Ryr1* and *Ryr3* mRNA were detected (**Fig. 3.1**).

## Results

**Fig. 3.1** | *Ryr1* and *Ryr3* mRNA expression in immune cells. Naive T cells ( $CD4^+CD62L^{high}CD44^{low}$ ) and MOG-specific B cells ( $B220^+CD19^+$ ) were isolated from mixed populations of lymph node cells and splenocytes. Effector T cells were enriched from draining lymph nodes of mice immunized against MOG<sub>35-55</sub> peptide. B cells were activated *in vitro* with 100 ng/ml LPS and 10  $\mu$ g/ml MOG<sub>35-55</sub>. Dendritic cells ( $CD11c^+$ ) were a kind gift from my colleague Tanja Litke. Bars represent the mean (+SEM) from three independent experiments normalized to the expression of beta-actin.

### 3.1.2 RyR1 and RyR3 are expressed in effector T cells *in vitro*

Having demonstrated that expression of *Ryr1* and *Ryr3* mRNA was found in effector T cells, we analyzed the kinetic of RyR expression in T cells upon unspecific stimulation with monoclonal antibodies or antigen-specific (MOG<sub>35-55</sub> peptide) stimulation *in vitro* (**Fig. 3.2**). We cultured total splenocytes of C57Bl/6 WT and TCR<sup>MOG</sup> (2D2, MOG-specific TCR transgenic) mice in the presence of anti-CD3/anti-CD28 antibodies and MOG<sub>35-55</sub> peptide, respectively, and analyzed  $CD4^+$  T cells 24 h, 48 h, 72 h, and 96 h after stimulation. *Ryr1* and *Ryr3* mRNA expression was determined by qRT-PCR. Increased levels of *Ryr1* mRNA were detected in T cells 48 h to 96 h after antibody stimulation, while *Ryr3* mRNA was not detected. After stimulation with MOG<sub>35-55</sub> peptide, *Ryr1* mRNA levels were increased in  $CD4^+$  T cells 72 h and 96 h after stimulation, and low levels of *Ryr3* mRNA were detected 96 h after stimulation.

Cells from the samples that were used for mRNA expression analysis were also used for immunocytochemistry for RyR1 and RyR3 expression (**Fig. 3.3**). According to the corresponding mRNA data, T cells expressed RyR1 72 h to 96 h after anti-CD3/anti-CD28 antibody treatment and both RyR1 and RyR3 72 h to 96 h after stimulation with MOG<sub>35-55</sub> peptide. By that, we could confirm expression of RyR1 and RyR3 in activated T lymphocytes.

## Results

**Fig. 3.2** | *Ryr1* and *Ryr3* mRNA expression in effector T cells. *Left panel*: Lymph node cells and splenocyte cultures from WT C57Bl/6 mice were stimulated with 1  $\mu$ g/ml anti-CD3 and 5  $\mu$ g/ml anti-CD28 antibodies. *Right panel*: Lymph node cells and splenocyte cultures from 2D2 mice were stimulated with 10  $\mu$ g/ml MOG<sub>35-55</sub> peptide. At indicated time points, T cells were purified via negative selection and used for mRNA isolation and real-time PCR analysis for *Ryr1* and *Ryr3*. Bars represent the mean (+SEM) from three independent experiments.

**Fig. 3.3** | RyR1 and RyR3 protein expression in effector T cells. The expression of RyR1 and RyR3 was assessed by ICC at indicated time points. **(A), (B)**: Lymph node cells and splenocyte cultures from WT mice were stimulated with 1  $\mu$ g/ml anti-CD3 and 5  $\mu$ g/ml anti-CD28 antibodies. **(C) – (F)**: Lymph node cells and splenocyte cultures from TCR<sup>MOG</sup> mice were stimulated with 10  $\mu$ g/ml MOG<sub>35-55</sub> peptide. T cells were purified via negative selection before fixation and antibody staining against RyR1 or RyR3. Nuclei were visualized with DAPI. Scale bar represents 25  $\mu$ m.

### 3.2 Generation and analysis of *Ryr1*<sup>-/-</sup>, *Ryr3*<sup>-/-</sup> and *Ryr* double knockout fetal liver chimeras

The *Ryr1* gene knockout results in early postnatal lethality in mice (TAKESHIMA *et al.*, 1994). Yet to investigate the effect of *Ryr1* deletion in immune cells, *Ryr1*<sup>-/-</sup>→WT fetal liver chimeras (FLCs) were generated (Fig. 3.4, A). For this purpose, hematopoietic progenitor cells derived from livers of *Ryr1*<sup>-/-</sup> fetuses were isolated at 14.5 days post conception and injected into lethally irradiated WT C57Bl/6 animals. Expression of the RFP reporter gene thereby allowed further identification of the newly generated donor cells. Blood analysis by FACS showed that reconstitution levels of hematopoietic cells was about 75–80 % for T cells (TCRβ<sup>+</sup>RFP<sup>+</sup>) and about 80–85 % for B cells (B220<sup>+</sup>RFP<sup>+</sup>) four weeks after transfer (Fig. 3.4, B).

**Fig. 3.4** | Scheme for the generation of fetal liver chimeras. See text and methods chapter 2.4.2 for detailed description.

## Results

Afterward, the mice were either used for phenotyping analyses or EAE induction. In parallel to generating *Ryr1*<sup>-/-</sup>→WT FLCs, *Ryr3*<sup>-/-</sup>→WT FLCs, *Ryr1* and *Ryr3* double knockout FLCs, respective heterozygous controls (Ctrl→WT; Ctrl) were generated and analyzed as well.

### 3.2.1 The immune system of *Ryr*-KO FLCs does not differ from that of control FLCs

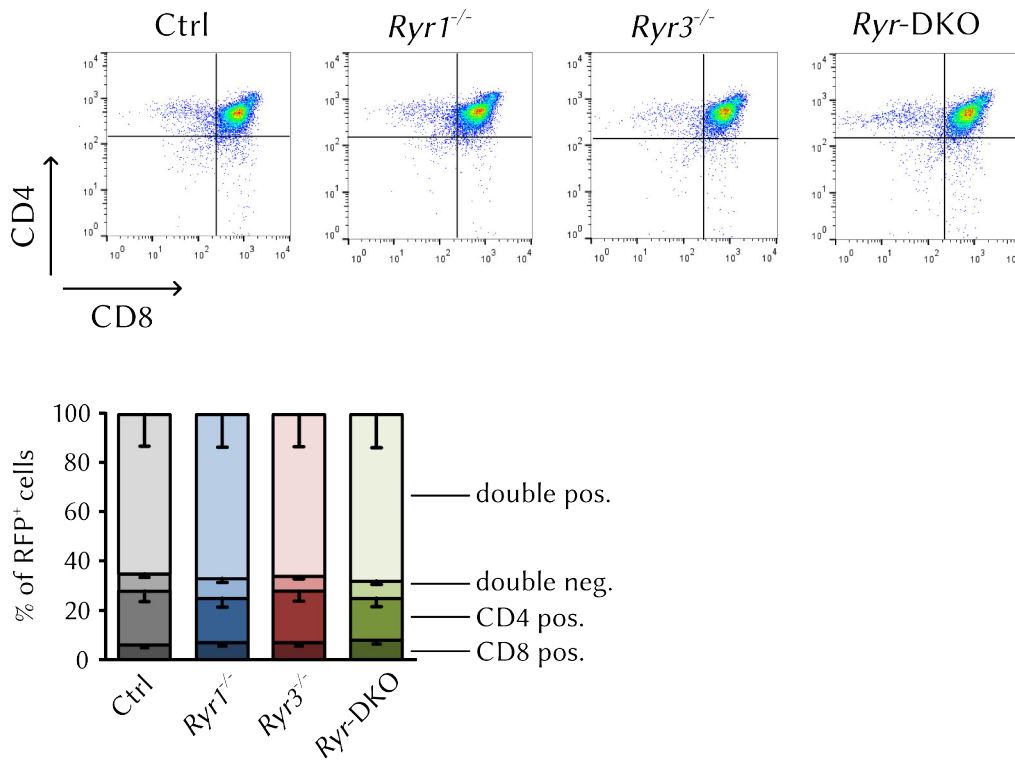

Chimeric mice presented healthy and showed no obvious abnormalities. The status and composition of the immune system in chimeras was examined in its naïve state. Thymi and spleens had normal appearance (not shown) and were similar in weight and cellularity (**Fig. 3.5**).

**Fig. 3.5** | Analysis of hematopoietic organs of fetal liver chimeric mice. In comparison with control mice, thymus and spleen of *Ryr3*<sup>-/-</sup> mice were not altered in weight (**A**) and cellularity (**B**). Bars represent the mean (+SEM) from three independent experiments.

Lymphoid progenitors generated in the bone marrow home to the thymus where they develop into mature T cells. During this process several checkpoints operate in a manner dependent on the TCR engagement and Ca<sup>2+</sup> signaling. Thymocytes differentiate from CD4<sup>-</sup>CD8<sup>-</sup> (double negative) cells into CD4<sup>+</sup>CD8<sup>+</sup> (double positive) cells and further into mature CD4<sup>+</sup> or CD8<sup>+</sup> single positive cells. These transition is severely disturbed when key signaling molecules, such as Zap70, are deleted. Therefore, the frequency of transgenic RFP CD4<sup>+</sup> and CD8<sup>+</sup> thymocytes in *Ryr* knockout FLCs was assessed by FACS staining (**Fig. 3.6**). Neither *Ryr1* nor *Ryr3* deletion changed the frequency of CD4<sup>+</sup> or CD8<sup>+</sup> cells or the rate of CD4<sup>+</sup>CD8<sup>+</sup> double positive thymocytes.

## Results

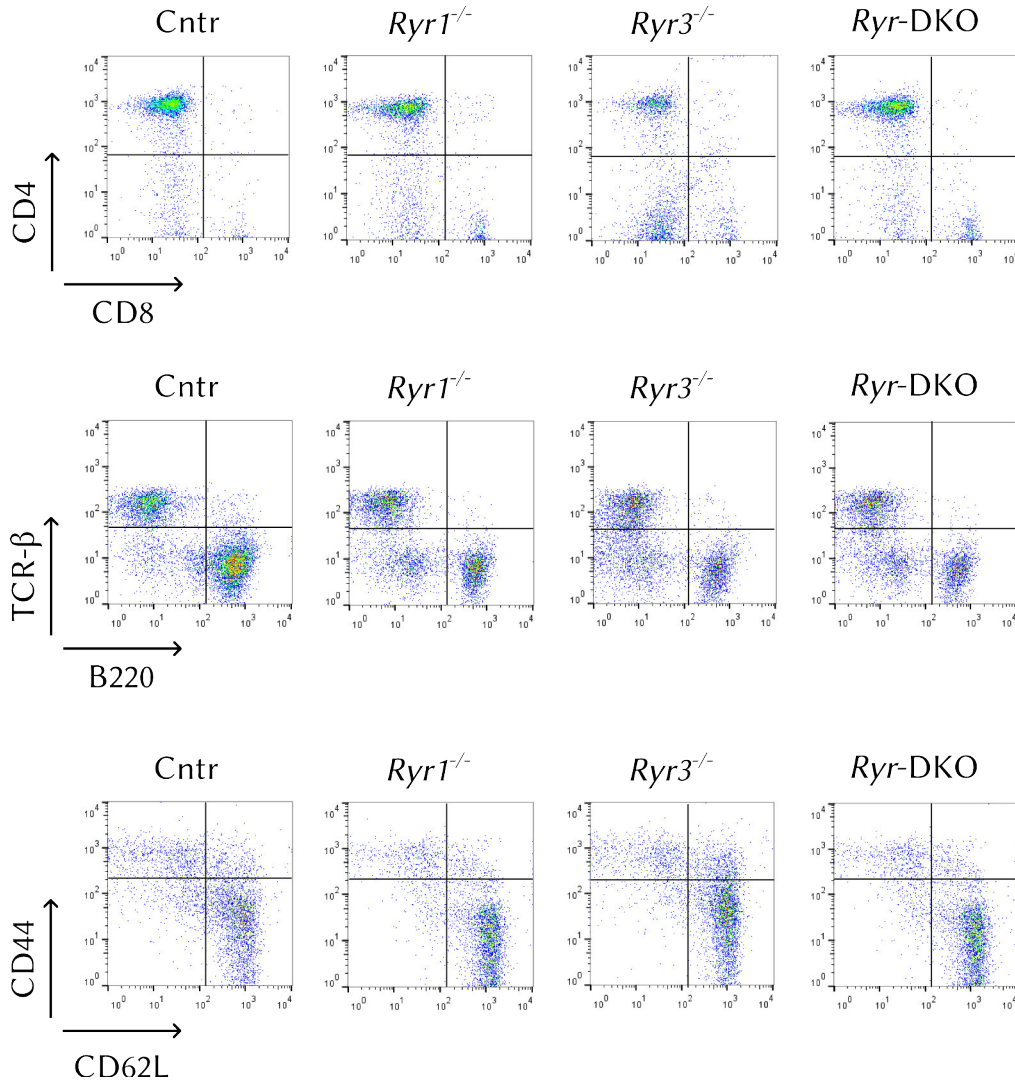

**Fig. 3.6** | The frequency of CD4<sup>+</sup> and CD8<sup>+</sup> cells in the thymus of *Ryr*-KO FLCs is similar to that of control FLCs. Single cell suspensions of thymocytes were stained and analyzed via flow cytometry for the expression of surface markers CD4 and CD8. To exclude host cells we gated on the RFP<sup>+</sup> population. Depicted are representative flow cytometry data (upper panel) and the quantification from three individually performed experiments (lower panel; bars represent mean+SEM).

Furthermore, the composition of the peripheral immune system of *Ryr*-KO FLCs was investigated in spleen, lymph nodes and blood. Cells of these organs did not differ from each other in the ratio of expression of the surface markers CD4 and CD8 (helper vs. cytotoxic T cells), TCR- $\beta$  and B220 (T cells vs. B cells) or CD44 and CD62L (effector vs. naïve T cells; **Fig. 3.7**).

Results

Spleen

Results

**B**

Lymph nodes

**Fig. 3.7** | *Ryr*-KO FLCs are similar to control FLCs in the composition of the peripheral immune system. Analyzed were (A) spleen, (B) lymph nodes and (C) blood for the ratio of CD4<sup>+</sup> to CD8<sup>+</sup> cells, T to B cells (TCR-β / B220) and the ratio of effector to naïve T cells (CD44 / CD62L; only data for spleen). Single cell suspensions of the indicated organs were prepared if necessary, depleted for erythrocytes and stained for the respective surface markers for analysis in flow cytometry. To analyze transgenic cells only, cells were gated on the RFP<sup>+</sup> population. Depicted are representative flow cytometry data (upper panels) and the quantification from three individually performed experiments (lower panel; bars represent mean+SEM).

### 3.2.2 *Ryr1* deficient T cells show diminished TCR dependent intracellular $\text{Ca}^{2+}$ response

T cells lacking *Ryr1* were less responsive to NAADP stimulation, and showed diminished intracellular  $\text{Ca}^{2+}$  signals upon stimulation with anti-CD3 antibody conjugated beads (WOLF *et al.*, 2015, manuscript in revision, and **Fig. 3.8**; Data kindly provided by Insa Wolf and Bjoern-Philip Diercks from the lab of Dr. A. Guse, UKE, Hamburg).

**Fig. 3.8** | *Ryr1* deficient T cells show diminished intracellular  $\text{Ca}^{2+}$  response upon TCR stimulation. *Ryr1*<sup>-/-</sup> and control T cells were loaded with the membrane permeable  $\text{Ca}^{2+}$  dyes Fluo-4 and Fura-2 as described (**chapter 2.8.1**) and stimulated with anti-CD3 antibody conjugated beads.

### 3.2.3 *Ryr1* deficient lymphocytes proliferate less in response to anti-CD3 antibodies stimulation

$\text{Ca}^{2+}$  signals are an essential mechanism for T cell activation and prompt the proliferative T cell response. However, inhibition of  $\text{Ca}^{2+}$  signals, for example with BZ194, a NAADP antagonist, results in diminished T cell activation and proliferation (DAMMERMANN *et al.*, 2009). We investigated if the proliferation of *Ryr* knockout lymphocytes in response to anti-CD3 stimulation was reduced compared to heterozygous control cells (**Fig. 3.9**). T lymphocytes from *Ryr1*<sup>-/-</sup>→WT FLCs proliferated in a dose-dependent manner to anti-CD3 stimulation, but significantly less in comparison to *Ryr1*<sup>+/-</sup>→WT FLC control cells (**Fig. 3.9, A**). The same was observed when cells were strongly stimulated with anti-CD3/anti-CD28 antibodies. In *Ryr*-DKO→WT lymphocytes, the proliferative response was similarly reduced, but not more than in *Ryr1* single KO cells. Obviously an additional knockout of *Ryr3* had no further effect on proliferation (**Fig. 3.9, B**). This became clearer when the proliferation of lymphocytes from *Ryr3*<sup>-/-</sup>→WT FLCs was analyzed (**Fig. 3.9, C**). Lymphocytes from *Ryr3*<sup>-/-</sup>→WT FLCs proliferated in a dose dependent manner to anti-CD3 antibody stimulation, but with no significant reduction to the control group. Cells from either control or chimeric mice proliferated substantially to stimulation with anti-CD3/anti-CD-28 antibodies and did not proliferate when left unstimulated.

## Results

**Fig. 3.9** | The knockout of *Ryr1*, but not of *Ryr3* attenuates the proliferative response of T lymphocytes derived from *Ryr1*<sup>-/-</sup>→WT and *Ryr*-DKO→WT FLCs in comparison to control FLCs (*Ryr1*<sup>+/-</sup>*Ryr3*<sup>-/-</sup>→WT). Cells were isolated from the LNs of (A) *Ryr1*<sup>-/-</sup>→WT, (B) *Ryr*-DKO→WT, and (C) *Ryr3*<sup>-/-</sup>→WT FLCs. From single cell suspensions of LN cells,  $3 \times 10^5$  cells per well were stimulated for 48 h with anti-CD3 and/or anti-CD28 antibodies in indicated concentrations before chasing with <sup>3</sup>[H]thymidine for another 16 h and measurement of <sup>3</sup>[H]thymidine incorporation. Medium (Med) served as negative control. Each condition was analyzed in triplicates. Bars represent the mean (+SEM) of three independent experiments. Statistical analysis was performed using a two-tailed Student's *t*-test (\**P* ≤ 0.05).

### 3.2.4 EAE induction in $Ryr1^{-/-}$ →WT FLCs

To assess the role of RyR1 in EAE,  $Ryr1^{-/-}$ →WT FLCs and respective control FLCs were immunized against MOG<sub>35-55</sub> peptide (Fig. 3.10).

**Fig. 3.10** |  $Ryr1^{-/-}$ →WT FLCs develop attenuated EAE. Control ( $n=20$ ) and  $Ryr1^{-/-}$ →WT ( $n=20$ ) FLCs were immunized against MOG<sub>35-55</sub> peptide. (A) EAE disease course and (B) weight change course of  $Ryr1^{-/-}$ →WT FLCs (blue line) and control FLCs ( $Ryr1^{-/-}$ → $Ryr3^{-/-}$ →WT; grey line). In (C) the day of disease onset and in (D) the percentage of disease free animals are shown for each group. In all panels the mean (+SEM) of three independent experiments is shown. Data were tested for statistical significance using the Mann-Whitney U test for clinical courses (A, B; \*\* $P \leq 0.01$ ; \* $P \leq 0.05$ ) and a two-tailed Student's  $t$ -test (C; ns  $P \geq 0.05$ ).

$Ryr1^{-/-}$ →WT FLCs developed first clinical symptoms about one day later than control animals (Fig. 3.10, A, C and D). Also, the progress of the disease during the acute phase was slightly delayed in  $Ryr1^{-/-}$ →WT FLCs and resulted in a milder disease at the peak than that of control FLCs. The chronic phase was characterized in both groups by persisting EAE symptoms that were, however, significantly less pronounced in  $Ryr1^{-/-}$ →WT FLCs (Fig.

## Results

**3.10, A).** In concordance with the clinical scores,  $Ryr1^{-/-} \rightarrow$ WT mice lost less weight during the course of EAE compared to control FLCs (**Fig. 3.10, B**). Therefore ablation of *Ryr1* in hematopoietic cells reduces the clinical severity of EAE.

### 3.2.5 EAE induction in *Ryr*-DKO $\rightarrow$ WT FLCs

*Ryr*-DKO $\rightarrow$ WT FLCs developed a disease onset and an acute phase that was similar to that of control animals (**Fig. 3.11, A, C and D**). This was in contrast to the EAE observed in  $Ryr1^{-/-} \rightarrow$ WT FLCs. However, the peak and the EAE progress was attenuated in *Ryr*-DKO $\rightarrow$ WT FLCs. Furthermore, some of the mice partially recovered from EAE symptoms, which was not observed in control animals or  $Ryr1^{-/-} \rightarrow$ WT FLCs. Likewise in EAE of  $Ryr1^{-/-} \rightarrow$ WT FLCs, *Ryr*-DKO $\rightarrow$ WT FLCs lost less weight than control FLCs (**Fig. 3.11, B**).

**Fig. 3.11** | *Ryr*-DKO $\rightarrow$ WT FLCs develop attenuated EAE. Control ( $n=6$ ) and *Ryr*-DKO $\rightarrow$ WT ( $n=7$ ) FLCs were immunized against MOG<sub>35-55</sub> peptide. (**A**) EAE disease course, and (**B**) weight change course of *Ryr*-DKO $\rightarrow$ WT FLCs (green line) and control FLCs ( $Ryr1^{-/-} \rightarrow Ryr3^{+/+}$ )

## Results

→WT; grey line). (C) Day of disease onset and (D) percentage of disease free animals for each group. In all panels the mean (+SEM) of two independent experiments is shown. Statistics were carried out using the Mann–Whitney U test for clinical courses (**A**; \* $P \leq 0.05$ ) and a two-tailed Student's *t*-test (**B, C**; \* $P \leq 0.05$ ).

We concluded that mice developed an attenuated course of EAE as far as *Ryr1* was deleted in hematopoietic cells as a single knockout or as a double KO in combination with *Ryr3*.

### 3.2.6 EAE induction in *Ryr3*<sup>-/-</sup>→WT FLCs

Our data on the expression of *Ryr3* in T cells and proliferative response of *Ryr3* deficient T cells are in agreement with previously published results (TAKESHIMA *et al.*, 1996). Consistently, *Ryr3*<sup>-/-</sup>→WT FLCs developed EAE on about the same day after immunization such as the control FLCs (**Fig. 3.12, A, C and D**). The onset and the acute phase of EAE proceeded similar in *Ryr3*<sup>-/-</sup>→WT and control FLCs and EAE symptoms peaked about that same day post immunization. In contrast to the amelioration noticed in *Ryr1*<sup>-/-</sup>→WT FLCs in the chronic phase, the disease progress was rather similar between *Ryr3*<sup>-/-</sup>→WT FLCs and control FLCs. Even though EAE progressed by tendency slightly milder in *Ryr3*<sup>-/-</sup>→WT FLCs, the difference did not reach statistically significance levels, whereas weight loss of *Ryr3*<sup>-/-</sup>→WT FLCs was significantly less severe compared to control mice (**Fig. 3.12, B**). However, these results showed that deletion of *Ryr3* in hematopoietic cells had only minor influence on the clinical course of EAE.

## Results

**Fig. 3.12** | *Ryr3*<sup>-/-</sup>→WT FLCs do not develop EAE different from that of control FLCs. Control (*n*=15) and *Ryr3*<sup>-/-</sup>→WT (*n*=18) FLCs were immunized against MOG<sub>35-55</sub> peptide. (A) EAE disease course, and (B) weight change course of *Ryr3*<sup>-/-</sup>→WT FLCs (red line) and control FLCs (*Ryr1*<sup>-/-</sup>→WT; grey line). In (C) the day of disease onset and (D) the percentage of disease free animals are shown for each group. In all panels the mean (+SEM) from three independent experiments is shown. Groups were statistically tested using the Mann-Whitney U test for clinical courses (A, B; \**P* ≤ 0.05, ns *P* ≥ 0.05) and a two-tailed Student's *t*-test (C; ns *P* ≥ 0.05).

### 3.2.7 Characterization of *Ryr*-KO T cells at the onset of EAE

In order to further investigate the impact of *Ryr* deletion on EAE pathogenesis, the status of infiltrating T cells in the CNS was analyzed in *Ryr1*<sup>-/-</sup>→WT FLCs, *Ryr*-DKO→WT FLCs and control FLCs at d14 p.i. (Fig. 3.13). To characterize their activation status, T cells were stained for the surface markers CD25 and CD69. It was found that T cells in the CNS from *Ryr1*<sup>-/-</sup>→WT FLCs were less activated than those from control FLCs.

## Results

**Fig. 3.13** | Encephalitogenic T cells from *Ryr1*<sup>-/-</sup> and *Ryr*-DKO FLCs express lower amount of the activation markers CD69 and CD25 and infiltrate less frequently into the CNS than T cells from control FLCs (*Ryr1*<sup>-/-</sup>*Ryr3*<sup>+/-</sup>→WT). Animals were sacrificed on d14 p. i. to recover T cells during the acute phase of EAE. Lymphocytes were isolated from the CNS

## Results

using Percoll density centrifugation. Single cell suspensions were then stained for flow cytometry. To analyze only transgenic T cells, cells were gated on the CD4<sup>+</sup>RFP<sup>+</sup> population. Depicted are representative flow cytometry data (upper panels) and the quantification from three individually performed experiments (lower panel; bars represent mean+SEM). Statistical analysis was performed using a two-tailed Student's *t*-test (\**P* ≤ 0.05, ns *P* ≥ 0.05).

### 3.3 The function of RyR3 in the CNS during EAE

The previous results indicated that a knockout of *Ryr3* in hematopoietic cells has no major effect on the clinical progression of EAE thus far as it was observed for *Ryr1*<sup>-/-</sup>. Accordingly, the T cell function was not severely affected by *Ryr3* deletion. However, in contrast to the rather low expression levels in T cells, *Ryr3* mRNA was found highly expressed in the brain and in the spinal cord of WT C57Bl/6 mice (**Fig. 3.14**).

**Fig. 3.14** | *Ryr3* mRNA is highly expressed in the CNS. Homogenates from total brain (*n*=3) and spinal cord (SC; *n*=3) were used for mRNA isolation and real-time PCR analysis.

#### 3.3.1 EAE induction in WT → *Ryr3*<sup>-/-</sup> bone marrow chimeras

In order to further investigate the role of RyR3 in the CNS during EAE in *Ryr3*<sup>-/-</sup> mice, bone marrow chimeras (BMCs) were generated by transferring bone marrow cells from CD45.1 WT mice into lethally irradiated *Ryr3*<sup>-/-</sup> animals, which were congenic CD45.2. CD45.1 → *Ryr3*<sup>+/-</sup> BMCs served as control animals. In contrast to *Ryr3*<sup>-/-</sup> → WT FLCs, these mice now exhibit the knockout of *Ryr3* in the CNS (and other tissues), while hematopoietic cells remain WT for RyR3. After successful reconstitution, EAE was induced by immunization against MOG<sub>35-55</sub> peptide (**Fig. 3.15**). No obvious differences between CD45.1 → *Ryr3*<sup>-/-</sup> and control animals were observed during the onset and early clinical phase of EAE (**Fig. 3.15 A, C and D**). However 14–15 days

## Results

after immunization in the EAE continued to progress in control CD45.1→*Ryr3*<sup>+/-</sup> BMCs but not in *Ryr3* KO recipients. (**Fig. 3.15 A**). In concordance with the clinical scores, CD45.1→*Ryr3*<sup>+/-</sup> BMCs lost less weight during the course of EAE compared to control BMCs (**Fig. 3.15, B**). Therefore, deficiency of RyR3 in the CNS—contrary to T cells or other hematopoietic cells—was determining EAE severity.

**Fig. 3.15** | *Ryr3* deficiency in non-hematopoietic cells attenuates EAE severity. Control ( $n=15$ ) and WT→*Ryr3*<sup>-/-</sup> ( $n=15$ ) BMCs were immunized against MOG<sub>35-55</sub> peptide. (**A**) EAE disease course, and (**B**) weight change course of WT→*Ryr3*<sup>-/-</sup> BMCs (red line) and control FLCs (grey line). (**C**) Day of disease onset. (**D**) Percentage of disease free animals. In all panels the mean (+SEM) of three independent experiments is shown. Statistics were carried out using the Mann–Whitney U test for clinical courses (**A**, \* $P \leq 0.05$ ) and a two-tailed Student's *t*-test (**B**, **C**; \* $P \leq 0.05$ , ns  $P \geq 0.05$ ).

### 3.3.2 Active EAE in *Ryr3*<sup>-/-</sup> mice

For the further experiments, mice with a germline knockout of *Ryr3* were used. In contrast to *Ryr1* knockout animals, mice homozygous for *Ryr3* deletion were healthy and fertile—though hyperlocomotion and impaired learning and memory were reported (TAKESHIMA *et al.*, 1996, KOUZO *et al.*, 1999). In these mice, EAE could be effectively induced by immunization against MOG<sub>35-55</sub> peptide (Fig. 3.16). No difference in disease incidence was found between control (*Ryr3*<sup>+/-</sup>) and *Ryr3*<sup>-/-</sup> mice (Fig. 3.16 A, C and D). Both groups developed EAE at day 9-10 after immunization and shared a similar early clinical phase of EAE (Fig. 3.16 A and C). However, the peak of EAE was reached 3-4 days earlier in *Ryr3*<sup>-/-</sup> animals and presented significantly lower clinical scores (Fig. 3.16 A). While control animals developed EAE as expected (MENDEL *et al.*, 1995), clinical symptoms of *Ryr3*<sup>-/-</sup> mice significantly improved during the chronic phase of EAE.

**Fig. 3.16** | *Ryr3*<sup>-/-</sup> mice develop attenuated EAE. Control ( $n=20$ ) and *Ryr3*<sup>-/-</sup> mice ( $n=20$ ) were immunized against MOG<sub>35-55</sub> peptide. (A) EAE disease course, and (B) weight change course of *Ryr3*<sup>-/-</sup> (red line) and control mice (grey line). (C) Day of EAE onset. (D) Percentage of disease free animals. In all panels the mean (+SEM) of three independent experiments is shown. Statistics were carried out using the Mann-Whitney U test for clinical courses (A, B; \*\*  $P \leq 0.01$ ; \*  $P \leq 0.05$ ) and a two-tailed Student's *t*-test (C; ns  $P \geq 0.05$ ).

## Results

### 3.3.3 Histology of *Ryr3*<sup>-/-</sup> EAE animals

Demyelination and axonal degeneration in the spinal cord are the main histopathological features of EAE that result from infiltration of encephalitogenic T cells and recruited macrophages. In order to characterize the pathology of EAE in *Ryr3*<sup>-/-</sup> mice, animals were analyzed at day 17 post immunization, when mice of the control group were at the peak of the disease. Fixed spinal cord tissue was used for preparation of paraffin sections and further analyzed by IHC for the frequency of infiltrating T cells, macrophages and activated microglia.

To determine the quantity of infiltrating T cells, tissue sections were stained for CD3<sup>+</sup> T cells (**Fig. 3.17, A**). It was found that the number of T cells in spinal cord sections of *Ryr3*<sup>-/-</sup> mice was significantly reduced compared to controls. A highly significant reduction in cell infiltrates was found when spinal cord sections were stained for the number of recruited MAC3<sup>+</sup> macrophages (**Fig. 3.17, B**).

## Results

**Fig. 3.17** | Less immune cells infiltrate the spinal cords of *Ryr3*<sup>-/-</sup> mice at the peak of EAE. Control (*n*=4) and *Ryr3*<sup>-/-</sup> (*n*=4) mice were immunized against MOG<sub>35-55</sub>. Spinal cords were isolated at the peak of EAE (d17 p. i.) and used for paraffin sections. Antibody stainings were performed for (A) CD3 (T cells) and (B) MAC3 (macrophages) and counterstained with Mayer's hemalum solution to visualize cell nuclei. For the statistical analysis, at least five sections from the cervical, thoracic and lumbar segment were investigated for each spinal cord. Bars represent mean (+SEM). Data were statistically tested using a two-tailed Student's *t*-test (\*\**P* ≤ 0.01, \**P* ≤ 0.05). Representative images are shown from animals with a clinical score of 6.0 (control) and 3.5 (*Ryr3*<sup>-/-</sup>).

Microglia are CNS resident immune cells of hematopoietic origin that permanently scan tissue for damage or infections. During inflammation microglia cells accumulate at the pathological site and can act as antigen-presenting cells for T helper cells. As they are potent producers of pro-inflammatory cytokines, they highly contribute to neuroinflammation. Upon activation, microglia change their morphology from a ramified to a roundish shape and strongly up-regulate Iba1 expression. Significantly less Iba1<sup>+</sup> microglia/activated macrophages were counted in spinal cord sections of *Ryr3*<sup>-/-</sup> mice compared to controls (**Fig. 3.18**). It was also observed that microglia were distributed more even in spinal cords from *Ryr3*<sup>-/-</sup> mice but accumulated dense at inflammatory sites in control animals.

**Fig. 3.18** | Less microglia co-localize at inflammatory sites in spinal cords of *Ryr3*<sup>-/-</sup> mice at the peak of EAE. Control (*n*=4) and *Ryr3*<sup>-/-</sup> (*n*=4) mice were immunized against MOG<sub>35-55</sub>. Spinal cords were isolated at the peak of EAE (d17 p. i.) and used for paraffin sections. Antibody stainings were performed for microglia marker Iba1 and counterstained with Mayer's hemalum solution to visualize cell nuclei. For the statistical analysis, at least five sections from the cervical, thoracic and lumbar segment were investigated for each spinal cord. Bars represent mean (+SEM). Data were statistically tested using a two-tailed Student's *t*-test (\*\**P* ≤ 0.01). Representative images are shown from animals with a clinical score of 6.0 (control) and 3.5 (*Ryr3*<sup>-/-</sup>).

## Results

Autoimmune inflammation of the CNS results in demyelination and axonal degradation. The extent of demyelination was assessed at the peak of EAE by Luxol fast blue-Periodic acid-Schiff stain (LFB-PAS; **Fig. 3.19, A**), while axon degradation was investigated by means of Bielschowsky's silver stain (BSS) in the chronic phase of EAE, 30 days after immunization (**Fig. 3.19, B**). Spinal cord sections of *Ryr3*<sup>-/-</sup> mice showed a significant reduction in demyelination and axonal pathology.

**Fig. 3.19** | Demyelination and axonal loss are significantly reduced in *Ryr3*<sup>-/-</sup> mice. Control ( $n=4$ ) and *Ryr3*<sup>-/-</sup> ( $n=4$ ) mice were immunized against MOG<sub>35-55</sub> peptide. **(A)** Spinal cords were isolated at the peak of EAE (d17 p. i.) and used for paraffin sections. To evaluate the amount of demyelination, slides were stained with LFB solution to detect myelin, combined with a PAS reaction to visualize exposed glycoproteins in the demyelinated regions. The percentage of demyelination was calculated for the area of the white matter. **(B)** Spinal cords were isolated at d30 p. i. for detection of axonal degradation by means of Bielschowsky's silver stain that gives nerve fibers a dark color. The percentage of axonal loss was calculated for the area of the white matter. For the statistical analysis, at least five

## Results

sections from the cervical, thoracic and lumbar segment were investigated for each spinal cord. Bars represent mean (+SEM). Data were statistically tested using a two-tailed Student's *t*-test (\*\* $P \leq 0.01$ , \* $P \leq 0.05$ ). Representative images are shown from animals with a clinical score of 6.0 (control) and 3.5 (*Ryr3*<sup>-/-</sup>) in (A), and a clinical score of 5.0 (control) and 3.0 (*Ryr3*<sup>-/-</sup>) in (B).

### 3.3.4 Spontaneous EAE in *Ryr3*<sup>-/-</sup>×2D2×IgH<sup>MOG</sup> mice

Induction of EAE is generally performed by active immunization of mice against myelin antigens, e. g. MOG<sub>35-55</sub> applied in strong immune adjuvants, or by the injection of pre-activated myelin specific T lymphocytes. Yet, it has been reported that mice that were generated by crossing MOG-specific T cell receptor transgenic 2D2 (TCR<sup>MOG</sup>) mice with IgH<sup>MOG</sup> mice (harbouring MOG-specific B cells) develop EAE spontaneously (BETELLI *et al.*, 2006, KRISHNAMOORTHY 2006). To investigate how deletion of *Ryr3* influences the course of spontaneous EAE (spEAE), *Ryr3*<sup>-/-</sup>×2D2 mice were crossed with IgH<sup>MOG</sup> mice and followed several months for the occurrence of EAE symptoms (Fig. 3.20). As in the previous experiments, *Ryr3*<sup>+/-</sup> littermates served as control animals.

*Ryr3*<sup>-/-</sup> developed spEAE about 80 days after birth, whereas control animals developed first clinical symptoms already with an average age of 48 days (Fig. 3.20, B). From the group of *Ryr3*<sup>-/-</sup> animals 40 % developed no disease at all, while only 20 % of control animals remained without clinical symptoms at the end of the observation period (Fig. 3.20, C). Compared to control animals, *Ryr3*<sup>-/-</sup> mice developed less severe EAE symptoms (Fig. 3.20, A). Similar to the EAE induced by active immunization, *Ryr3*<sup>-/-</sup> and control animals showed an identical clinical course of EAE during disease onset, but differed at the peak and in the chronic phase of the disease. While control animals developed disease with full paralysis of the hind limbs, gang ataxia was the most severe symptom in *Ryr3* deficient animals.

## Results

**Fig. 3.20** | Spontaneous EAE in *Ryr3* deficient mice. Control ( $n=5$ ) and *Ryr3*<sup>-/-</sup> mice ( $n=5$ ) were monitored daily for the (spontaneous) development of EAE symptoms. (A) EAE disease course of *Ryr3*<sup>-/-</sup> × 2D2 × IgH<sup>MOG</sup> (red line) and control mice (grey line). (B) Day of onset of each group. (C) Percentage of disease free animals. In all panels the mean (+SEM) of three independent experiments is shown. Statistics were carried out using the Mann–Whitney U test for clinical courses (A, \* $P \leq 0.05$ ) and a two-tailed Student's *t*-test (B; \* $P \leq 0.05$ ).

### 3.3.4.1 Histology of *Ryr3*<sup>-/-</sup> × 2D2 × IgH<sup>MOG</sup> EAE animals

Spinal cord sections of *Ryr3*<sup>-/-</sup> × 2D2 × IgH<sup>MOG</sup> EAE mice were prepared at the end of the observation period (Fig. 3.21). No remaining immune cell infiltrates—either positive for CD3 or MAC3—were found in spinal cord, neither in control nor in *Ryr3*<sup>-/-</sup> mice at this time point of EAE (not shown). Yet, demyelination was significantly reduced in *Ryr3*<sup>-/-</sup> mice, as well as the intensity of axonal degradation.

## Results

**Fig. 3.21** | Demyelination and axonal loss are reduced in *Ryr3*<sup>-/-</sup>×2D2×IgH<sup>MOG</sup> mice. Spinal cords ( $n=4$  for each group) were isolated at the end of the observation period (d30 after spEAE onset) and used for paraffin sections. **(A)** shows the evaluation of demyelination. Samples were stained with luxol fast blue solution to detect myelin, combined with a periodic acid-Schiff reaction to visualize exposed glycoproteins in the demyelinated regions. The percentage of demyelination was calculated for the area of the white matter. **(B)** shows the evaluation of axonal degradation by means of Bielschowsky's silver stain. The percentage of axonal loss was calculated for the area of the white matter. For the statistical analysis, at least five sections from the cervical, thoracic and lumbar segment were investigated for each spinal cord. Bars represent mean (+SEM). Data were statistically tested using a two-tailed Student's *t*-test (\* $P \leq 0.05$ ). Representative images are shown from animals with a clinical score of 6.0 (control) and 3.0 (*Ryr3*<sup>-/-</sup>).

### 3.3.5 Analysis of the immune system of *Ryr3*<sup>-/-</sup> mice

The ablation of *Ryr3* had beneficial effects on the progression of EAE, either induced by active immunization or under spontaneous conditions. In addition, the data from bone marrow and fetal liver chimeras strongly argue that this extenuation was likely mediated by the deletion of RyR3 in cells of the CNS rather than loss of RyR3 in hematopoietic cells. However, chimeric

## Results

mice never display a complete reconstitution of hematopoietic cells. Therefore, we analyzed the immune system of *Ryr3* deficient mice in order to reveal or exclude the role of Ryr3 expression in immune cells in described results of EAE experiments.

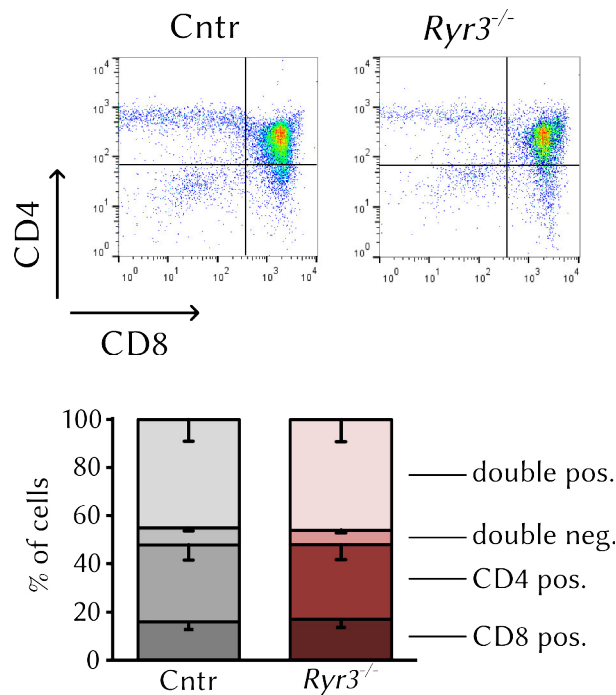

First of all, thymus and spleen from *Ryr3*<sup>-/-</sup> mice were indistinguishable from those of heterozygous control littermates by visual inspection and did not differ in organ weight or cellularity (**Fig. 3.22**).

**Fig. 3.22** | Analysis of hematopoietic organs of *Ryr3*<sup>-/-</sup> mice. In comparison with control mice, thymus and spleen of *Ryr3*<sup>-/-</sup> mice were not altered in size (**A**), weight (**B**) and cellularity (**C**). Bars represent the mean (+SEM) from three independent experiments.

Secondly, it was investigated if deficiency of *Ryr3* had an impact on T cell development in the thymus. Therefore, thymocytes from *Ryr3*<sup>-/-</sup> mice were stained for CD4 and CD8 surface markers (**Fig. 3.23**). Ablation of *Ryr3* had no obvious effect on the frequency of CD4<sup>+</sup> or CD8<sup>+</sup> single positive, as well as double positive (CD4<sup>+</sup>CD8<sup>+</sup>) or double negative (CD4<sup>-</sup>CD8<sup>-</sup>) thymocytes.

## Results

**Fig. 3.23** | The frequency of CD4<sup>+</sup> and CD8<sup>+</sup> cells in the thymus of *Ryr3*<sup>-/-</sup> mice is similar to that of controls. Single cell suspensions of thymocytes were stained and analyzed via flow cytometry for the expression of surface markers CD4 and CD8. Depicted are representative flow cytometry data (upper panel) and the quantification from three individually performed experiments (lower panel; bars represent mean+SEM).

Furthermore, the composition of the peripheral immune system was investigated in spleens and lymph nodes of *Ryr3*<sup>-/-</sup> mice. The organs were analyzed for the frequency of CD4<sup>+</sup> and CD8<sup>+</sup> T cells, naïve and effector CD4 T cells, the ratio between T and B cells and expression of the surface activation markers CD25 and CD69 (**Fig. 3.24 and 3.25**). The status of the immune system in lymph nodes was similar in *Ryr3*<sup>-/-</sup> and control mice. However, in *Ryr3*<sup>-/-</sup> mice there was a shift in the ratio of CD4<sup>+</sup> to CD8<sup>+</sup> cells towards the cytotoxic T cell population. This was also observed in the spleen, where this shift was even more pronounced. Apart from this, the immune system of *Ryr3*<sup>-/-</sup> was virtually indistinguishable from that of controls.

## Results

**Fig. 3.24** | The composition of the immune system in LNs of *Ryr3*<sup>-/-</sup> mice is similar to that of control mice. Single cell suspensions of lymph nodes from *Ryr3*<sup>-/-</sup> mice were stained and analyzed via flow cytometry for expression of surface markers CD4 and CD8, CD62L and CD44, TCR-β and B220, CD25 and CD69. Depicted are representative flow cytometry data (upper panel) and the quantification from three individually performed experiments (lower panel; bars represent mean+SEM).

## Results

**Fig. 3.25** | The composition of the immune system in spleens of *Ryr3*<sup>-/-</sup> mice is similar to that of control mice. Single cell suspensions of spleens from *Ryr3*<sup>-/-</sup> mice were depleted from erythrocytes and stained and analyzed via flow cytometry for expression of surface markers CD4 and CD8, CD62L and CD44, CD25 and CD69. Depicted are representative flow cytometry data (upper panel) and the quantification from three individually performed experiments (lower panel; bars represent mean+SEM). Statistical analysis was performed using a two-tailed Student's *t*-test (\**P* ≤ 0.05).

## Results

### 3.3.5.1 Proliferation of *Ryr3*<sup>-/-</sup> lymphocytes

*Ryr3*<sup>-/-</sup> lymphocytes were tested for their proliferation abilities in response to stimulation with anti-CD3 antibodies or MOG<sub>35-55</sub> peptide (on the 2D2 transgenic background), respectively (Fig. 3.26). Lymph node cells proliferated in a dose dependent manner to 48 h stimulation with anti-CD3 antibodies. However, no differences were observed between *Ryr3*<sup>-/-</sup> and control cells (Fig. 3.26, A). Little, but yet significant reduction in proliferation was observed when lymphocytes were strongly stimulated for 48 h with anti-CD3/anti-CD28 antibodies. Lymphocytes from mice with 2D2 (TCR<sup>MOG</sup>) background proliferated significantly less when stimulated with 1.0 µg/ml MOG<sub>35-55</sub> peptide, but not with 10 µg/ml, where only tendency levels in the reduction of proliferation were observed (Fig. 3.26, B).

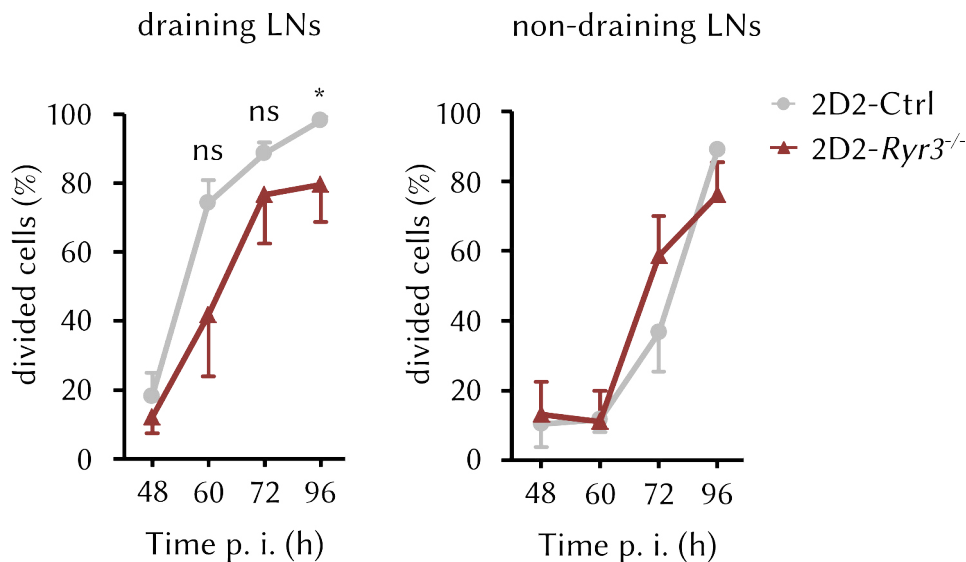

**Fig. 3.26** | The knockout of *Ryr3* does not severely alter the proliferative response of lymphocytes or splenocytes. Cells were isolated from LNs of *Ryr3*<sup>-/-</sup> mice (A), and spleen of 2D2-*Ryr3*<sup>-/-</sup> mice (B). From single cell suspensions,  $3 \times 10^5$  cells per well were stimulated for 48 h with anti-CD3 and/or anti-CD28 antibodies (A), or MOG<sub>35-55</sub> peptide or ovalbumin (OVA) (B) in indicated concentrations before chasing with <sup>3</sup>[H]thymidine for another 16 h and measurement of <sup>3</sup>[H]thymidine incorporation. Medium (Med) served as negative control. Each condition was analyzed in triplicates. Bars represent the mean (+SEM) of three independent experiments and were compared using a two-tailed Student's *t*-test (\**P* ≤ 0.05).

## Results

### 3.3.5.2 *In vivo* proliferation of *Ryr3*<sup>-/-</sup> T cells

As a consequence of immunization, naïve T cells become activated by dendritic cells through TCR stimulation. This stimulus results in rapid T cell proliferation in the draining lymph nodes (JENKINS *et al.*, 2001).

To test how T cells from *Ryr3*<sup>-/-</sup> mice would proliferate in the secondary lymphoid organs *in vivo*, CFSE-labeled, RFP<sup>+</sup> CD4<sup>+</sup> T cells from either *Ryr3*<sup>-/-</sup> or control mice were transferred into C57BL/6 recipient mice. Analysis of T cell proliferation (CFSE dilution) was performed 48 h, 60 h, 72 h and 96 h after immunization against MOG<sub>35-55</sub> peptide for the draining (inguinal and popliteal LNs) and for the non-draining lymph nodes (cervical and axillary LNs; **Fig. 3.27**). Even though *Ryr3* deficient T cells proliferated less in draining lymph nodes than control T cells at every investigated time point, attenuation was only significant 96 h after immunization. No difference in proliferation between *Ryr3*<sup>-/-</sup> and control cells was observed in the non-draining lymph nodes.

**Fig. 3.27** | Proliferation of MOG-specific T cells upon immunization is not affected by *Ryr3* deficiency. An equal amount of isolated CD4<sup>+</sup> MOG peptide-specific T cells was labeled with CFSE and injected i.v. into C57BL/6 host animals. After 48 h, mice were immunized against MOG<sub>35-55</sub> peptide (200 ng PTX d0 and d2 p. i.). Single cell suspensions from the draining and non-draining lymph nodes were prepared 48 h, 60 h, 72 h and 96 h after immunization. The dilution of CFSE was analyzed by flow cytometry for the CD4<sup>+</sup>RFP<sup>+</sup> cell population. Bars represent the mean (+SEM) of two independent experiments with two mice per time point and group. Statistics were performed using a two-tailed Student's *t*-test (\**P* ≤ 0.05; ns *P* ≥ 0.05).

### 3.3.5.3 Encephalitogenic potential of *Ryr3* deficient T cells

In order to investigate the encephalitogenic potential of *Ryr3* deficient T cells, we transferred MOG-specific *Ryr3*<sup>-/-</sup> cells (*Ryr3*<sup>-/-</sup>×2D2) in OT II mice, followed by immunization against MOG<sub>35-55</sub> peptide. T cells from OT II mice are reactive against ovalbumin. This allowed the investigation how MOG-specific *Ryr3*<sup>-/-</sup> T cells contribute to EAE in an otherwise EAE resistant host. We observed that EAE in mice that received *Ryr3*<sup>-/-</sup>×2D2 T cells developed not differently from controls (Fig. 3.28), supporting our previous results indicating that *Ryr3* deletion does not impair T cell function or the ability of T cells to become encephalitogenic.

**Fig. 3.28** | The encephalitogenic potential of MOG-specific T cells is not affected by *Ryr3* deficiency. An equal amount of *Ryr3*<sup>-/-</sup>×2D2 T cells and respective controls was transferred into OT II mice 48 h prior immunization against MOG<sub>35-55</sub> peptide. (A) EAE disease course of OT II mice that received *Ryr3*<sup>-/-</sup>×2D2 cells (red line) and control cells (grey line). (B) shows the percentage of survival of the animals. (C) Day of onset of each group. (D) Percentage of disease free animals. In all panels the mean (+SEM) of three independent experiments is shown. Statistics were carried out using the Mann-Whitney U test for clinical courses (A, \**P* ≤ 0.05) and a two-tailed Student's *t*-test (B; \**P* ≤ 0.05).

## Results

### 3.3.5.4 Antigen recall assay

After priming in the secondary lymphoid organs, T cells start to proliferate and gain their migratory phenotype that allows them to enter the blood circulation. In case of MOG<sub>35-55</sub> peptide-induced EAE, T cells cross the BBB and infiltrate into the CNS, where they re-encounter their specific antigen and become reactivated and promote inflammation.

Lymphocytes from draining lymph nodes and splenocytes were tested for their antigen recall response at day 8 post immunization. The cells were isolated and restimulated with MOG<sub>35-55</sub> peptide and assayed 48 h later (Fig. 3.29). As observed before lymphocytes and splenocytes proliferated in a dose dependent manner to MOG<sub>35-55</sub> peptide stimulation, but with no significant difference between *Ryr3*<sup>-/-</sup> and control cells.

**Fig. 3.29** | *Ryr3*<sup>-/-</sup> lymphocytes from the periphery are not impaired to antigen recall after immunization. MOG peptide-specific *Ryr3*<sup>-/-</sup> and control mice were immunized against MOG<sub>35-55</sub> peptide. At d8 p. i.,  $3 \times 10^5$  cells per well from single cell suspensions of (A) LNs and (B) spleen were stimulated for 48 h with MOG<sub>35-55</sub> peptide in indicated concentrations before chasing with <sup>3</sup>[H]thymidine for another 16 h and measurement of <sup>3</sup>[H]thymidine incorporation. Medium (Med) served as negative control. Each condition was analyzed in triplicates. Bars represent the mean (+SEM) of three independent experiments.

### 3.4 The function of RyR3 in astrocytes during the course of EAE

#### 3.4.1 Expression of RyR3 in primary murine astrocytes

Astrocytes and microglia play active and crucial roles during EAE in several ways, such as antigen presentation, chemokine and cytokine production, and the provision of a suitable environment for T cell attraction and activation (RAIVICH, 2005, NAIR *et al.*, 2008). Primary cultures of astrocytes and microglia were analyzed for expression of *Ryr3* mRNA. In contrast to the steady state (**Fig. 3.30, A**), highly elevated levels of *Ryr3* mRNA were found in activated astrocytes, whereas activation of microglia resulted only in a minor increase in *Ryr3* mRNA expression (**Fig. 3.30, B**). RyR3 protein was detectable in astrocytic cultures by immunostaining presumably in the ER compartment (**Fig. 3.30, C**).

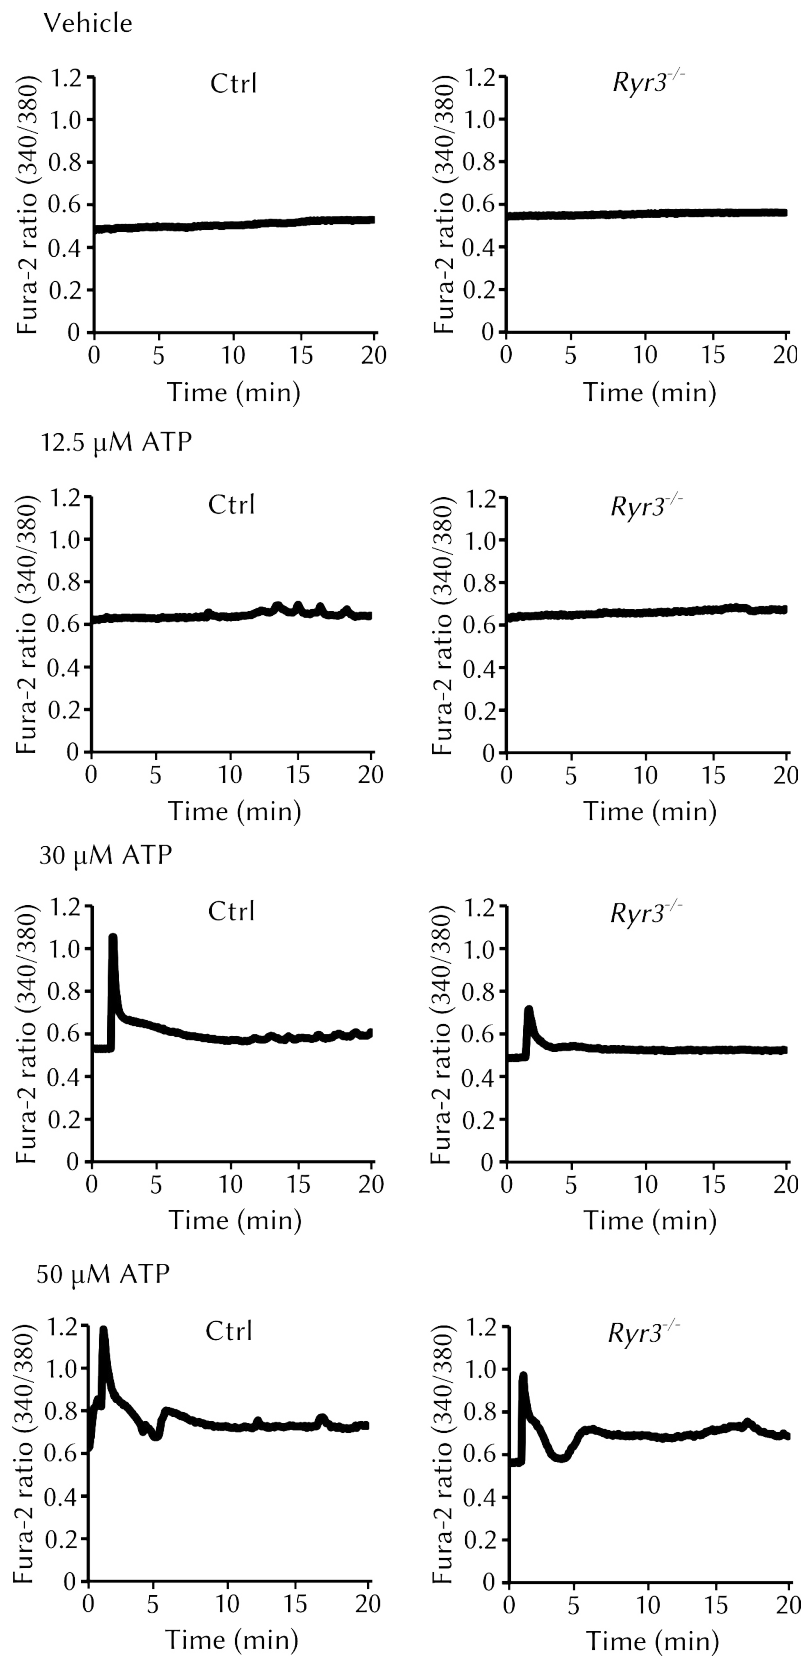

**Fig. 3.30** | *Ryr3* mRNA is highly expressed in activated astrocytes. Cultures of (A) unstimulated and (B) LPS stimulated (100 ng/ml) astrocytes (ACs) and microglia (MG) were analyzed for *Ryr3* mRNA expression. Expression of *Ryr3* mRNA in midbrain neurons (Neu) served as a reference. Bars represent the mean (+SEM) from three independent experiments. RNA lysates from midbrain neurons were a kind gift from Anna-Elisa Roser, Dept. of Neurology, University Medicine Göttingen. (C) Functional RyR3 is expressed in astrocytes. Primary cultures of astrocytes (RFP) were stimulated with LPS (100 ng/ml) and stained against RyR3 (green). Nuclei were visualized with DAPI (blue). Scale bar represents 50  $\mu$ m.

### 3.4.2 *Ryr3*<sup>-/-</sup> astrocytes show altered Ca<sup>2+</sup> signaling responses

Astrocytes are linked in a network via intercellular channels also known as gap junctions, which allow the fast passage of ions and small molecules between cells. Stimulation of astrocytes evokes an increase of intracellular Ca<sup>2+</sup> that propagates to neighboring cells via the gap junctions, resulting in progressive Ca<sup>2+</sup> waves that spread throughout the astrocytic network. ATP is a potent stimulator of intracellular Ca<sup>2+</sup> signals in astrocytes (JEREMIC *et al.*, 2001) therefore we used this naturally occurring compound to investigate Ca<sup>2+</sup> signals in *Ryr3*<sup>-/-</sup>, and heterozygous control astrocytes. Primary astrocytes from neonatal mice were loaded with the membrane permeable Ca<sup>2+</sup> dyes Fluo-4 and Fura-2 as described (**chapter 2.8.1**) and stimulated with 30 μM ATP. The resulting Ca<sup>2+</sup> response was imaged for additional 20 min (**Fig. 3.31**).

Neither control nor *Ryr3*<sup>-/-</sup> astrocytes showed spontaneous Ca<sup>2+</sup> fluxes when imaged after treatment with calcium buffer as vehicle control. Substantial Ca<sup>2+</sup> signaling was detected when control cells were stimulated with 30 μM or 50 μM ATP. A strong peak was observed 5–10 sec after ATP application and oscillating patterns in Ca<sup>2+</sup> signaling were detected in some cells starting after about 5 min and continued until the end of the measuring. An attenuated form of this initial peak and fewer oscillations—or oscillations with lower amplitudes—were observed in *Ryr3*<sup>-/-</sup> astrocytes. No initial spark was observed when astrocytes, either controls or *Ryr3*<sup>-/-</sup>, were stimulated with 12.5 μM ATP. However, some control cells began to oscillate after about 10–12 min, which was not observed in *Ryr3*<sup>-/-</sup> cells.

## Results

**Fig. 3.31** | *Ryr3*<sup>-/-</sup> astrocytes show altered Ca<sup>2+</sup> signals in response to ATP stimulation.

## Results

Astrocytes were loaded with the  $\text{Ca}^{2+}$  dyes Fluo-4 and Fura-2. The Fura-2 ratio (340/380 nm) was imaged over total 20 min. After 1 min, the cells were stimulated with ATP. Calcium buffer served as vehicle control. Depicted are the means of acquired  $\text{Ca}^{2+}$  signals of all cells within the measuring field.

### 3.4.3 *Ryr3*<sup>-/-</sup> astrocytes secrete less glutamate upon stimulation

Glutamate is an excitatory transmitter which is released by astrocytes to modulate the functions of nearby neurons (MALARKEY AND PARPURA, 2008) and can be mediated by  $\text{Ca}^{2+}$  dependent exocytosis (PARPURA *et al.*, 1994). HUA *et al.* reported in 2004 that the  $\text{Ca}^{2+}$  that was necessary for the glutamate release came mainly from internal stores and that an activation of  $\text{IP}_3\text{Rs}$  and RyRs was required. Primary astrocytes from *Ryr3*<sup>-/-</sup> mice were stimulated and analyzed for their release of glutamate (Fig. 3.32).

**Fig. 3.32** | Glutamate release is reduced in *Ryr3*<sup>-/-</sup> astrocytes. Primary astrocytes were stimulated with indicated concentrations of IFN-γ/TNF-α or 30 µM ATP for 1 h or left untreated (medium control; Med). Levels of glutamate in the medium of astrocytes were determined by colorimetric quantification. Bars represent the mean (+SEM) of three independent experiments. Statistical analysis was performed using a two-tailed Student's *t*-test (\* $P \leq 0.05$ , ns  $P \geq 0.05$ ).

#### 3.4.4 *Ryr3*<sup>-/-</sup> primary astrocytes produce lower amounts of CCL2, CCL5, CXCL10 and TNF- $\alpha$ *in vitro*

In general, astrocytes support neuronal transmission, maintain neuronal integrity and control homeostasis of the BBB. In case of neuroinflammation they can exert both neuroprotective or neurotoxic functions by the production of chemokines and cytokines (LIEBERMAN *et al.*, 1989, CHOI *et al.*, 2014). LPS are large bacteria derived endotoxins that cause strong immune responses and are known to induce chemokine and cytokine production in astrocytes (LIEBERMAN *et al.*, 1989). To investigate whether *Ryr3*<sup>-/-</sup> astrocytes responded differently from control astrocytes to strong stimuli, LPS was applied to primary cultures of cortical astrocytes and RNA was isolated after 4 h and 24 h of stimulation to analyze the expression of *Ccl2*, *Ccl5*, *Cxcl10* and *Tnfa* mRNA (Fig. 3.33). First of all it was observed that both control and *Ryr3*<sup>-/-</sup> astrocytes did respond to LPS, either applied for 4 h or 24 h. However, there was a substantial reduction in *Ccl2*, *Ccl5* and *Tnfa* mRNA expression after 4 h in *Ryr3*<sup>-/-</sup> astrocytes, while no significant difference was found for the expression of *Cxcl10* mRNA. The same tendency was observed in astrocytes that were stimulated with LPS for 24 h. Only background levels of expression were detected after the same time period in control (medium) stimulated cells.

## Results

**Fig. 3.33** | Chemokine and cytokine mRNA expression in response to LPS stimulation is reduced in *Ryr3*<sup>-/-</sup> astrocytes. Primary astrocytes were stimulated with 100 ng/ml LPS for 4 h or 24 h or left untreated (medium control; Med). *Ryr3* mRNA levels were determined by real-time PCR analysis. Bars represent the mean (+SEM) of three independent experiments. Statistical analysis was performed using a two-tailed Student's *t*-test (\*\* $P \leq 0.01$ , \* $P \leq 0.05$ ).

During EAE, IFN- $\gamma$  and TNF- $\alpha$  were secreted by infiltrating encephalitogenic Th1 cells in order to promote macrophage recruitment, and higher levels of these cytokines were found in the CSF of MS patients (KROENKE *et al.*, 2008). Thus it was investigated how astrocytes would respond to these stimuli (Fig. 3.34). In addition, the cells were treated with ATP, which induced powerful Ca<sup>2+</sup> signals, and glutamate, a transmitter that was secreted by astrocytes themselves upon stimulation as described (Fig. 3.31 and Fig. 3.32).

## Results

**Fig. 3.34** | Chemokine and cytokine mRNA expression is reduced in *Ryr3*<sup>-/-</sup> astrocytes after stimulation with IFN- $\gamma$ /TNF- $\alpha$ . Primary astrocytes were stimulated with 100 ng/ml IFN- $\gamma$ /TNF- $\alpha$ , 100  $\mu$ M glutamate (Glu), 30  $\mu$ M ATP or left untreated (medium control; Med) for 1 h. *Ryr3* mRNA levels were determined by real-time PCR analysis. Bars represent the mean (+SEM) of three independent experiments. Statistical analysis was performed using a two-tailed Student's *t*-test (\*\* $P \leq 0.01$ , \*\*\* $P \leq 0.001$ , ns  $P \geq 0.05$ ).

### 3.4.5 Astrocytes isolated from spinal cords of *Ryr3*<sup>-/-</sup> mice produce lower amounts of CCL2, CCL5 and CXCL10 at the onset of EAE

During the onset of EAE, chemokines regulate the migration of immune cells towards sites of inflammation and contribute to leukocyte infiltration into the CNS parenchyma (KUNKEL AND BUTCHER, 2002). Astrocytes have proven to be a potent producer of chemokines in the context of neuroinflammation, and particular in EAE (ENG *et al.*, 1996). Since it was observed *in vitro* that *Ryr3*<sup>-/-</sup> astrocytes were less responsive to stimuli and produced lower amounts of chemokines and cytokines, *Ryr3*<sup>-/-</sup> astrocytes of EAE mice were investigated *ex vivo* at the onset of EAE. Spinal cords of EAE animals were isolated and split longitudinally. One half of the spinal cord tissue was used to isolate astrocytes via MACS purification, while the other half was used to purify T cells via negative selection. From both populations the RNA was extracted and analyzed by qPCR. Astrocytes were analyzed for *Ccl2*, *Ccl5* and *Cxcl10* mRNA expression (Fig. 3.35, A) and T cells for the expression of chemokine receptor *Cxcr3*, *Cxcr4*, *Ccr5*, *Ccr6* and *Ccr7* mRNA (Fig. 3.35, B). Animals from both control and *Ryr3*<sup>-/-</sup> had a clinical score of 1.0 at the time point of tissue collection (d11 p. i.). There, astrocytes from *Ryr3*<sup>-/-</sup> mice expressed significantly less *Ccl2*, *Ccl5* and *Cxcl10* mRNA compared to controls (Fig. 3.35, A). Additionally, T cells were investigated for expression of chemokine receptor mRNA. While no significant differences in mRNA expression levels were found between *Ryr3*<sup>-/-</sup> and control cells, levels of *Cxcr3*, *Ccr6* and *Ccr7* mRNA were by tendency lower in *Ryr3*<sup>-/-</sup> T cells. In neurodegenerative disorders, astrocytes are also known to express adhesion molecules, thus facilitating leukocyte entry into the CNS. Among these molecules, ICAM-1 and VCAM-1 were expressed by astrocytes (DIETRICH, 2002, GIMENEZ *et al.*, 2004), but expression levels were similar between *Ryr3*<sup>-/-</sup> and control astrocytes at the onset of EAE (Fig. 3.35, C).

**Fig. 3.35** | Chemokine and cytokine mRNA expression is reduced in *Ryr3*<sup>-/-</sup> astrocytes during EAE, while there were no changes in chemokine receptor mRNA expression in encephalitogenic T cells of the same animal. *Ryr3*<sup>-/-</sup> and control mice were immunized against MOG<sub>35-55</sub> peptide. Spinal cords were isolated from perfused animals at d11 p. i., and astrocytes and T cells were either isolated by MACS or purified by gradient centrifugation and negative selection. Lysates from isolated astrocytes were used for real-time PCR analysis for expression of *Ccl2*, *Ccl5* and *Cxcl10* mRNA (**A**), while T cells were analyzed for *Cxcr3*, *Cxcr4*, *Ccr5*, *Ccr6* and *Ccr7* mRNA expression (**B**). Bars represent the mean (+SEM) of three independent experiments. Statistical analysis was performed using a two-tailed Student's *t*-test (\*\* $P \leq 0.01$ , \* $P \leq 0.05$ , ns  $P \geq 0.05$ ).

### 3.4.6 Activation status and quantity of infiltrating *Ryr3*<sup>-/-</sup> T cells

At the peak (d17 p. i.) of the EAE, fewer T cells and macrophages were found in spinal cords of *Ryr3*<sup>-/-</sup> mice (**Fig. 3.17**). It was also found that *Ryr3*<sup>-/-</sup> astrocytes produced less chemokines at the onset of EAE as well as upon stimulation with Th1 related cytokines (**Fig. 3.34**; **Fig. 3.35, A**). Thus the activation status and the quantity of T cells during the acute phase of EAE was investigated in the spinal cord (d14 p. i.; **Fig. 3.36**). While *Ryr3*<sup>-/-</sup> and control CD4<sup>+</sup> T cells were found equally activated within the spinal cord, the total CD4<sup>+</sup> cell count was reduced significantly. However, the activation status and quantity of CD4<sup>+</sup> T cells was similar between *Ryr3*<sup>-/-</sup> and controls in the lymph nodes and spleen before disease onset (d8 p. i.; **Fig. 3.37**), indicating that fewer T cells—even though equally activated—home into the CNS.

## Results

**Fig. 3.36** | Activation status and quantity of infiltrating *Ryr3*<sup>-/-</sup> T cells. *Ryr3*<sup>-/-</sup> and control mice (each  $n=3$ ) were immunized against MOG<sub>35-55</sub> peptide. Spinal cords were isolated from PBS perfused animals at d14 p. i., and lymphocytes were isolated by gradient centrifugation. Cells were stained and analyzed by flow cytometry for the activation markers CD25, CD69 and CD44 as well as the frequency of naïve T cells (CD62L expression). For the analysis, cells were gated on the CD4<sup>+</sup> population. The absolute number of CD4<sup>+</sup> cells within the spinal cord was quantified with the help of counting beads and calculated on the organ weight. Bars represent mean+SEM. Statistical analysis was performed using a two-tailed Student's *t*-test (\* $P \leq 0.05$ ).

## Results

**Fig. 3.37** | The quantity and activation status of T cells in the periphery is not altered in *Ryr3*<sup>-/-</sup> animals before EAE onset. *Ryr3*<sup>-/-</sup> and control mice (each *n*=3) were immunized against MOG<sub>35-55</sub> peptide. Lymph nodes and spleen were isolated from PBS perfused animals at d8 p. i., homogenized and depleted for erythrocytes. Cells were stained and analyzed by flow cytometry for the activation markers CD25 and CD69. The absolute number of CD4<sup>+</sup> cells within lymph nodes and spleen was quantified with the help of counting beads and calculated on the organ weight. For the analysis, cells were gated on the CD4<sup>+</sup> population. Bars represent mean+SEM.

### 3.4.7 T cell migration towards *Ryr3*<sup>-/-</sup> astrocytes conditioned medium *in vitro*

To determine whether the lower chemokine production in *Ryr3*<sup>-/-</sup> astrocytes affected the migration capability of T cells, *in vitro* testing by means of transwell migration assays was employed (Fig. 3.38). Supernatants from stimulated *Ryr3*<sup>-/-</sup> and control astrocytes were used as testing agents for encephalitogenic WT T cells. It was observed that fewer T cells migrated to supernatants of *Ryr3*<sup>-/-</sup> astrocytes that had been stimulated with IFN- $\gamma$ /TNF- $\alpha$  compared to control supernatants. The same effect was seen in the assay using glutamate stimulated astrocyte supernatants. Migration towards supernatants of ATP treated *Ryr3*<sup>-/-</sup> astrocytes was comparable to that of ATP stimulated control astrocytes.

**Fig. 3.38** | WT T cells transmigrate less towards *Ryr3*<sup>-/-</sup> astrocytes derived supernatant containing medium. *Ryr3*<sup>-/-</sup> and control astrocytes were stimulated with 100 ng/ml IFN- $\gamma$ /TNF- $\alpha$ , 100  $\mu$ M glutamate (Glu), 30  $\mu$ M ATP or left untreated (medium control; Med) for 2 h. Supernatants were collected and 1:10 dilutions were used as testing agents. WT T cells were isolated from draining LNs of immunized animals at d9 p. i. and allowed to transmigrate for 5 h ( $1 \times 10^4$  T cells/well). The frequency of transmigrated cells was determined by flow cytometry. Bars represent the mean (+SEM) of three independent experiments. Statistical analysis was performed using a two-tailed Student's *t*-test (\* $P \leq 0.05$ , ns  $P \geq 0.05$ ).

### 3.4.8 MHCII expression is not altered in *Ryr3*<sup>-/-</sup> astrocytes and microglia

Under neuroinflammatory conditions, microglia and under some conditions also astrocytes up-regulate MHC-II molecules for optimal APC function and T cell restimulation in the CNS (RANSOHOFF AND ESTES, 1991). However, *Ryr3*<sup>-/-</sup> astrocytes and microglia did not differ from controls in their level of MHC-II expression upon IFN- $\gamma$  stimulation (Fig. 3.39).

Results

**Fig. 3.39** | MHCII expression in *Ryr3*<sup>-/-</sup> primary astrocytes and microglia is not altered compared to controls. MHCII expression was assessed in CD11b<sup>+</sup> astrocytes (A) and F4/80<sup>+</sup> microglia (B) by flow cytometry after 24 h stimulation with 100 ng/ml IFN- $\gamma$ .

### 3.4.9 Dantrolene treated C57Bl/6 WT mice develop attenuated EAE

The muscle relaxant dantrolene exhibits its effect by the selective blockage of RyR1 and RyR3 (with preference for RyR1), and is used in the clinic for the treatment of malignant hyperthermia (MH). As for its specificity for RyR1 and RyR3—but not RyR2—it came into focus for this study as a pharmacological tool to interfere with RyR signaling during EAE. A cohort of WT C57Bl/6 mice was immunized against MOG<sub>35-55</sub> peptide. The mice were treated once a day with 20 mg/kg dantrolene in 10 % DMSO in PBS, or received 10 % DMSO as a vehicle control. The treatment was carried out starting on the day of immunization and was terminated when the first clinical symptoms appeared in control mice (**Fig. 3.40 A, C and D**). First clinical symptoms appeared at about day 12 after immunization in control mice, two days before first signs of EAE were observed in the group of dantrolene treated animals (**Fig. 3.40, C**). In the control group, the course of EAE peaked on day 19 with an average score of about 6, whereas dantrolene treated mice developed a delayed and significantly ameliorated disease (**Fig. 3.40, A**). It was found that weight loss occurred in both groups of mice, but was less pronounced in dantrolene treated group of mice (**Fig. 3.40, B**). In addition to the clinical data, histological analysis on the tissue collected d25 p. i. showed that demyelination and the severity of axon damage were strongly reduced in spinal cords of dantrolene treated mice (**Fig. 3.40, E and F**).

## Results

**Fig. 3.40 A–D** | Dantrolene treated mice develop strongly attenuated and delayed EAE. Mice ( $n=10$  per group) were immunized against MOG<sub>35-55</sub> peptide. Dantrolene solved in 10 % DMSO was applied i.p. at 20 mg/kg daily starting at d0 until disease onset of mice of the control group. Injections of 10 % DMSO served as controls. **(A)** EAE disease course, and **(B)** weight change course of dantrolene treated mice (purple line) and DMSO treated mice (grey line). **(C)** Day of disease onset. **(D)** Percentage of disease free animals. In all panels the mean (+SEM) of two independent experiments is shown. Statistics were carried out using the Mann–Whitney U test for clinical courses **(A, B)**;  $**P \leq 0.01$  and a two-tailed Student's  $t$ -test **(C)**;  $*P \leq 0.05$ .

## Results

**Fig. 3.40 (E) and (F)** | Demyelination and axonal loss are reduced in dantrolene treated mice. Spinal cords ( $n=3$  for each group) were isolated at the end of the observation period (d25 p. i.) and used for paraffin sections. (E) shows the evaluation of demyelination. Samples were stained with luxol fast blue solution to detect myelin, combined with a periodic acid-Schiff reaction to visualize exposed glycoproteins in the deymelinated regions. The percentage of demyelination was calculated for the area of the white matter. (F) shows the evaluation of axonal degradation by means of Bielschowsky's silver stain. The percentage of axonal loss was calculated for the area of the white matter. For the statistical analysis, at least five sections from the cervical, thoracic and lumbar segment were investigated for each spinal cord. Bars represent mean (+SEM). Data were statistically tested using a two-tailed Student's  $t$ -test (\*\* $P \leq 0.01$ ). Representative images are shown from animals with a clinical score of 7.0 (DMSO) and 3.0 (dantrolene treated).

## 4 Discussion

### 4.1 Expression of RyRs in effector T cells

Present investigations on RyRs in C57Bl/6 mice started with the evaluation of *Ryr1* and *Ryr3* mRNA expression in murine immune cells, including naïve T cells, effector T cells, resting B cells, activated B cells and dendritic cells. *Ryr1* and *Ryr3* mRNA was expressed in effector T cells, with notable higher levels of *Ryr1* mRNA rather than *Ryr3*. No copies of *Ryr1* or *Ryr3* mRNA were found instead in naïve T or B cells and only minimal amounts of *Ryr1* or *Ryr3* mRNA were detected in dendritic cells (**Fig. 3.1**). RyRs are very large proteins—with over one hundred exons—making them the largest known ion channels. Even though the half-life is not known for RyR1 and RyR3, it is estimated for about eight *days* for RyR2 (SANTONASTASI AND WEHRENS, 2006). In comparison, the half-life of beta-actin, which is a commonly used housekeeping gene, is about 24 h. It is thus very likely that sufficient mRNA levels of RyRs may only be detectable in (fast) dividing cells when lots of mRNA copies are produced like it happens during the proliferation of T cells, but not in cells that are resting or in a steady state.

The expression of RyR1 and RyR3 proteins in rat effector T cells, previously shown by CORDIGLIERI *et al.* (2010), was confirmed in this study in mouse effector T cells. The kinetic of RyR1 and RyR3 expression in splenic T cells was determined within the first 96 h upon stimulation with either anti-CD3/CD28 antibodies or MOG<sub>35-55</sub> peptide (**Fig. 3.2**). This result confirmed the assumption that *Ryr* mRNA is primarily detectable during phases of T cell proliferation rather than in unstimulated cells. In a support of the real-time PCR data, the expression of RyR1 and RyR3 proteins could be detected by fluorescent staining in effector T cells (**Fig. 3.3**).

### 4.2 The role of RyR1 expression in T cells during EAE

T cell activation relies on the fast increase in free intercellular Ca<sup>2+</sup> that is initially triggered by IP<sub>3</sub>Rs and most probably, RyRs. The evidence of RyR1 and RyR3 expression in rat and murine effector T cells supported this hypothesis. We further addressed the importance of RyR1 for T cell activation with the help of RyR knockout mice. *Ryr1*<sup>-/-</sup> (TAKESHIMA *et al.*, 1994), *Ryr3*<sup>-/-</sup> (TAKESHIMA *et al.*, 1996) and *Ryr1*<sup>-/-</sup>*Ryr3*<sup>-/-</sup> mice (IKEMOTO *et al.*,

## Discussion

2008), each crossed to RFP reporter (expressed from Rosa26 locus) mice, provided the basis for the current study. However *Ryr1* deficient, but not *Ryr3*, mice die soon after birth. However, as we were interested in RyR1 function in T cells, we bypassed these circumstances with the generation of chimeric mice (fetal liver chimeras, FLCs), by reconstitution of irradiated WT mice with embryonal *Ryr1*<sup>-/-</sup> hematopoietic progenitor cells (**chapter 2.4.2 and Fig. 3.4**). To generate a comparable condition for the analysis of *Ryr3* deficient or DKO T cells. *Ryr1*<sup>+/-</sup>*Ryr3*<sup>+/-</sup> mice were mated with *Ryr1*<sup>+/-</sup>*Ryr3*<sup>-/-</sup> and embryos of appropriate genotypes were used for FLC production. The distribution of the genotypes among the fetuses followed the Mendelian rules and resulted in 37.5 % controls and *Ryr3*<sup>-/-</sup> single KOs, but only 12.5 % *Ryr1*<sup>-/-</sup> single KOs and double KOs. This has complicated generation of FLCs, as not in every mating all genotypes were present. In any case, expression of the RFP fluorescent reporter gene by the respective KO cells allowed us the validation of sufficient hematopoietic cell reconstitution that for B cell lineage usually exceeded 80 %, whereas for peripheral T cells remaining host derived population ranged 25-40%. This underscores the need for congenic marker (RFP) to restrict the analysis to donor derived T cells. Comparing to control chimeras, the reconstitution with *Ryr1*<sup>-/-</sup> hematopoietic progenitor cells did not influence the weight or cellularity of thymus and spleen (**Fig. 3.5**). Neither it altered T cell development in the thymus (**Fig. 3.6**), nor the composition of the peripheral immune system (**Fig. 3.7**). The same was observed for *Ryr3*<sup>-/-</sup> and *Ryr*-DKO. Altogether, *Ryr1* and *Ryr3* seem not to play a major role during T cell development, which is concordant with detectable expression of these receptors only in differentiated effector but not naïve T lymphocytes.

Binding of peptide-MHC complexes by TCRs of naïve T cells results in T cell activation (JENKINS *et al.*, 2001), followed by rapid proliferation and differentiation into effector cells (SEDER AND AHMED, 2003). We analyzed T cells from *Ryr1*<sup>-/-</sup>, *Ryr3*<sup>-/-</sup> and *Ryr*-DKO→WT FLCs for their ability to proliferate in response to anti-CD3 or anti-CD3/CD28 antibody stimulation (**Fig. 3.9**). *Ryr*-KO FLCs were compared with heterozygous control FLCs (*Ryr1*<sup>+/-</sup>*Ryr3*<sup>+/-</sup>→WT) and showed decreased proliferation in response to TCR stimulation. Our results were supported by the data of our collaborating partners from the lab of Dr. A. Guse (UKE, Hamburg) on the role of RyR1 in calcium signaling during T cell activation (WOLF *et al.*, 2015, manuscript in revision and **Fig. 3.8**): WOLF and colleagues demonstrated that *Ryr1*<sup>-/-</sup> played crucial role for the formation of early, initial intracellular Ca<sup>2+</sup> signals in T cells upon stimulation of TCR. This finding is in agreement with results that indicated a possible role of RyR1 for effector T cell activation in the rat (CORDIGLIERI *et al.*, 2010). However, the additional knockout of *Ryr3* had no further attenuating effect on T cell proliferation (**Fig. 3.9**), and T cells lacking *Ryr3* alone did not proliferate differently from controls (**Fig. 3.9**). These results again fit to the mRNA expression data and we concluded that RyR1—in contrast to RyR3—is the more important isoform for T cell activation.

After priming and proliferation in the lymph nodes, T cells enter the blood

## Discussion

circulation to search for antigen (GOVERMAN, 2009). We assumed that the reduced ability of *Ryr1*<sup>-/-</sup> T cells to proliferate in response to TCR stimulation would also influence the clinical outcome of EAE. We induced EAE in *Ryr1*<sup>-/-</sup>→WT FLCs by active immunization against MOG<sub>35-55</sub> peptide (**Fig. 3.10**) and observed that mice with *Ryr1* deficiency in hematopoietic cells developed an attenuated disease course. We also observed a slight delay during the acute phase of EAE. However, the day of disease onset was not significantly altered in *Ryr1*<sup>-/-</sup>→WT FLCs. Since the majority of T cells in *Ryr1*<sup>-/-</sup>→WT FLCs were lacking *Ryr1*, the delayed and attenuated disease course could be explained by a fewer number of postactivated T cells that leave the LNs where they proliferate upon immunization. This was supported by the lower frequency of T cells found in the CNS of *Ryr1*<sup>-/-</sup>→WT FLCs at d14 of the disease and was accompanied by lower expression of the surface activation markers CD25 and CD69 on these cells (**Fig. 3.13**). Future experiments will show if the attenuation of EAE in *Ryr1*<sup>-/-</sup>→WT FLCs is restricted to the deficiency of RyR1 in T cells. Even though the mRNA data concerning the expression of *Ryr1* in immune cells do not support this possibility, it cannot be generally excluded that RyR1 plays functions in other hematopoietic cells. A potential objective for investigations might be the antigen presentation to T cells by dendritic cells in the LNs, since we showed that *Ryr1* mRNA is expressed in these cells, even though at minimal levels (**Fig. 3.1**).

Next, EAE was induced in *Ryr*-DKO→WT FLCs, which developed a similar attenuated disease course as observed in *Ryr1*<sup>-/-</sup>→WT FLCs (**Fig. 3.11**). While EAE symptoms were significantly reduced in *Ryr*-DKO→WT FLCs at the peak of EAE, the disease course showed no signs of a delay during the acute phase. In addition, some mice partially recovered during the chronic phase, which was not observed in *Ryr1*<sup>-/-</sup>→WT FLCs. This resulted in considerable deviations in the mean clinical score, that complicates conclusive interpretation of the EAE results in the chronic phase of *Ryr*-DKO→WT experiments. However, T cells from *Ryr*-DKO→WT FLCs were found in a lower number and also less activated in the CNS (**Fig. 3.13**). Anyway, the effect of the additional *Ryr3* ablation was rather minimal. This became even more clear when we analysed EAE in *Ryr3*<sup>-/-</sup>→WT FLCs. Though these mice developed an EAE that was by tendency milder than in controls at the chronic stage of disease (**Fig. 3.12**), the difference to controls was minimal and not statistically significant. The results supported the *in vitro* observations (**Fig. 3.36 and chapter 3.3.5**, discussed later) that *Ryr3* deletion alone does not have a strong impact on T cell function and thus on the EAE development.

We assume that amelioration of EAE symptoms in *Ryr1*<sup>-/-</sup>→WT FLCs was mediated by *Ryr1* deletion in T cells. Future experiments will show if this holds true for T cell activation in the lymph nodes, thus leading to fewer T cells that home for the CNS, or T cell reactivation within the CNS.

The generation of fetal liver chimeras allowed us the investigation of *Ryr1* deletion, even though we could not breed *Ryr1*<sup>-/-</sup> mice. However, since

reconstitution of hematopoietic cells was never 100 %, we could not rule out that our results were influenced by the remaining endogenous T cells that are WT for *Ryr1*. So, prospective experiments should be performed in OT II host mice whose T cells are specific against the non-self antigen ovalbumine (OVA) and do not respond to MOG<sub>35-55</sub> immunization. By that, an influence of remaining endogenous T cells, that potentially harbor MBP-specific ones, on the outcome of EAE should be eliminated. A second approach to study RyR1 function would be the generation of a conditional KO for *Ryr1*. This would avoid early lethality and allow the investigator to control the usage of *Ryr1*<sup>-/-</sup> at different stages of EAE in specific populations. Since we were interested specifically in T cell function, a T cell specific KO for the *Ryr1* gene would further specify the role of RyR1 in T cells during EAE.

### 4.3 The role of RyR3 in EAE

Homozygous *Ryr3*-KO mice are viable and fertile, allowing EAE experiments in adult non-chimeric animals. Mice with whole-body *Ryr3* deletion showed a significantly ameliorated EAE course after active immunization against MOG<sub>35-55</sub> peptide compared to *Ryr3*<sup>+/-</sup> controls (**Fig. 3.16**). Heterozygous littermates served as suitable control animals since we found no differences in the clinical outcome of EAE between *Ryr3*<sup>+/-</sup> and *Ryr3*<sup>+/+</sup> mice (not shown). Interestingly, the results differed from the EAE observed in *Ryr3*<sup>-/-</sup>→WT FLCs and we assumed that deletion of *Ryr3* in cells that did not derive from the hematopoietic lineage were responsible for disease attenuation.

Considerable expression of RyR3 was reported for the mammalian brain (MURAYAMA AND OGAWA, 1996), and we confirmed expression of *Ryr3* mRNA for the total brain and the spinal cord tissues of C57Bl/6 mice (**Fig. 3.14**). We investigated whether the observed attenuation of EAE in *Ryr3*<sup>-/-</sup> mice was due to the deletion of *Ryr3* in the CNS and so we generated bone marrow chimeras (BMCs) by the transfer of *Ryr3*<sup>+/+</sup> bone marrow cells into irradiated *Ryr3*<sup>-/-</sup> recipient mice. EAE in these animals proceeded similar to that of germ line *Ryr3*<sup>-/-</sup> mice (**Fig. 3.15**). In any case, mice shared an identical onset and acute phase of EAE with the respective controls, while disease proceeded significantly milder at the peak and during the chronic phase of EAE.

Histological analysis revealed fewer infiltrating T cells and macrophages in the CNS of *Ryr3*<sup>-/-</sup> mice (**Fig. 3.17**). We also detected fewer reactive microglia at the inflammatory sites (**Fig. 3.18**) and observed less demyelination as well as axonal loss (**Fig. 3.19**). Interestingly, while the frequency of CNS infiltrating T cells was significantly lower in *Ryr3*<sup>-/-</sup> mice, the activation status of T cells was similar to that of controls (**Fig 3.36**) when we investigated the situation in the acute phase of EAE.

## Discussion

Thymus and spleen developed similar in *Ryr3*<sup>-/-</sup> mice, and no alterations in thymic T cell development were observed (**Fig. 3.22 and Fig. 3.23**). However, we found a shift in the ratio of CD4<sup>+</sup> / CD8<sup>+</sup> T cells towards the cytotoxic T cell population in lymph nodes and spleen of *Ryr3*<sup>-/-</sup>. Apart from that, the composition of the immune system in lymph nodes and spleen of *Ryr3*<sup>-/-</sup> mice was similar to that of controls (**Fig. 3.24 and Fig. 3.25**). As well as observed in *Ryr3*<sup>-/-</sup>→WT FLCs (**Fig. 3.12**), T lymphocytes from *Ryr3*<sup>-/-</sup> mice proliferated similar to controls upon TCR stimulation *in vitro* (**Fig. 3.26**). We could confirm this by the analysis of *in vivo* proliferation of transferred MOG-specific *Ryr3*<sup>-/-</sup> T cells in the draining lymph nodes after immunization (**Fig. 3.27**). There was also no impairment in the ability of *Ryr3*<sup>-/-</sup> T cells to recall antigen *in vitro* after previous priming in the secondary lymphoid organs (**Fig. 3.29**). The latter result matched to unchanged T cell numbers in lymph nodes and spleen one day before EAE onset (**Fig. 3.37**). By transfer of MOG-specific 2D2 *Ryr3*<sup>-/-</sup> T cells into OT II mice (homozygous tg/tg genotype) we tested whether or not specific ablation of *Ryr3* in T cells would affect EAE development upon immunization (**Fig. 3.28**). In OT II mice OVA-specific T cells do not respond to MOG immunization making the animals resistant to active EAE unless supplemented with exogenous T cells. Under these conditions, EAE development would be exclusively driven by the transferred T cells. On the other hand, OT II mice harbor a normal immune system to assure for example normal priming of T cells in the lymph nodes or antigen presentation in the CNS. However, we observed no significant differences in the EAE between mice that received MOG-specific *Ryr3*<sup>-/-</sup> or control T cells.

We concluded, that *Ryr3* deletion did not affect the proliferative response of T cells upon TCR dependent stimulation, either *in vitro* or *in vivo*, or their ability to leave the lymphoid organs in order to home for the CNS. Furthermore we demonstrated that *Ryr3*<sup>-/-</sup> T cells were not altered in their activation status after restimulation in the CNS.

Spontaneous EAE is of great advantage to study autoimmune CNS disease without active immunization or transfer of *in vitro* activated encephalitogenic T cell blasts. It results from the presence of T cells and B cells that are both specific for the same autoantigen MOG. We crossed our TCR<sup>MOG</sup>×*Ryr3*<sup>-/-</sup> mice to IgH<sup>MOG</sup> mice to investigate spontaneous EAE in the context of *Ryr3* deficiency. We demonstrated that *Ryr3*<sup>-/-</sup>×TCR<sup>MOG</sup>×IgH<sup>MOG</sup> mice developed EAE less frequently and later in life than *Ryr3*<sup>+/-</sup>×TCR<sup>MOG</sup>×IgH<sup>MOG</sup> control mice. Furthermore, *Ryr3* deficient animals had reduced EAE severity (**Fig. 3.20**) If we assume that *Ryr3* deletion in T cells does not affect the clinical outcome of EAE, this result seemed to be surprising at first glance, since spontaneous EAE strongly relies on T cell–B cell interactions. However, also in spontaneous model, *Ryr3* was deleted systemically, and not specifically in T cells. So actually, the clinical data indirectly supported our initial hypothesis that deletion of *Ryr3* in cells of the CNS mediated the observed EAE attenuation.

## 4.4 The importance of RyR3 in astrocytes

Astrocytes are the major population of glia cells in the CNS and are involved in numerous processes within the CNS, such as brain homeostasis, neuronal support and the recycling of excess neurotransmitters. Together with endothelial cells, astrocytes are also involved in maintaining the integrity of the blood-brain barrier. There, astrocytes form specialized endfeet that are in close contact to the intraparenchymal blood vessels. In case of smaller injuries or infections, astrocytes may become activated by inflammatory factors such as cytokines and release neuromodulators such as chemokines themselves to recruit microglia and circulating immune cells to the pathological site. During severe neuroinflammation the sustained release of pro-inflammatory cytokines and chemokines may allow peripheral immune cells, that were recruited to the CNS by sensing chemokine gradients, the migration across the blood-brain barrier, thereby supporting the generation of chronic neuroinflammatory diseases.

Activated astrocytes respond with an increase of intracellular  $\text{Ca}^{2+}$  that can spread throughout the astrocytic network in oscillatory waves via gap junctions, thereby triggering the activation of neighboring astrocytes. In order to test whether or not RyR3 contributes to the generation of  $\text{Ca}^{2+}$  signals in cultures of primary astrocytes, we induced strong  $\text{Ca}^{2+}$  signals by the application of ATP and measured the  $\text{Ca}^{2+}$  response by subcellular  $\text{Ca}^{2+}$  imaging (**Fig. 3.31**) Astrocytes responded with a fast and sudden increase of intracellular  $\text{Ca}^{2+}$  to ATP, followed by oscillating  $\text{Ca}^{2+}$  signals in some cells. However, the  $\text{Ca}^{2+}$  response was attenuated in astrocytes lacking *Ryr3*. This was supported by the findings that  $\text{Ca}^{2+}$  dependent release of the common neurotransmitter glutamate was reduced in *Ryr3*<sup>-/-</sup> astrocytes upon activation.

The sustained production of chemokines under inflammatory conditions plays a key role for the manifestation of chronic neuroinflammatory diseases, such as EAE or MS. We tested whether deletion of *Ryr3* attenuated the ability of astrocytes to produce certain chemokines, including CCL2, CCL5 and CXCL10, which represent important chemoattractants for the recruitment of T cells and monocytes. In fact, production of these chemokines was notably reduced in *Ryr3*<sup>-/-</sup> astrocytes upon stimulation with the pro-inflammatory and CD4<sup>+</sup> T cell related cytokines IFN- $\gamma$  and TNF- $\alpha$ . (**Fig. 3.34**). We confirmed the attenuated ability of *Ryr3*<sup>-/-</sup> astrocytes to produce chemokines also under EAE conditions (**Fig. 3.35**). The lower frequency of T cells within the corresponding spinal cords (**Fig. 3.36**) supported the hypothesis that RyR3 is highly involved in the activation of astrocytes and their ability to produce and secrete chemokines for the recruitment of immune cells, without directly affecting the activation status of T cells. We demonstrated with the help of transwell migration assays that the reduction in chemokine secretion by *Ryr3*<sup>-/-</sup> astrocytes was sufficient to attenuate the ability of T cells to transmigrate across a membrane towards the supernatants of IFN- $\gamma$  and

TNF- $\alpha$  stimulated *Ryr3*<sup>-/-</sup> astrocytes (**Fig. 3.38**).

Earlier reports demonstrated the ability of astrocytes to function as antigen presenting cells in the context of MHC-II expression under neuroinflammatory conditions. We could detect similar levels of MHC-II expression in *Ryr3*<sup>-/-</sup> and control astrocytes and assumed that attenuation of *Ryr3*<sup>-/-</sup> EAE was not mediated by the disability of *Ryr3*<sup>-/-</sup> astrocytes to act as antigen presenting cells in the CNS (**Fig. 3.39**). We found that MHC-II expression by microglia was not altered by *Ryr3* deletion, assuming that antigen presentation was not further affected by the deficiency of *Ryr3*<sup>-/-</sup>.

## 4.5 Pharmacological approaches to study RyRs

Pharmacological targeting of the NAADP signaling pathway has been used in rat effector T cells and Lewis rat adoptive transfer EAE. CORDIGLIERI and colleagues showed that the treatment with BZ194, an analogue of nicotinic acid, ameliorates active and passive EAE in Lewis rats (2010). However, this compound has not yet been tested in clinical trials of any kind.

Inhibition of RyR function by the muscle relaxant dantrolene is the common therapy for patients suffering from malignant hyperthermia. We took advantage from the specificity of dantrolene for the RyR1 and RyR3 isoform and applied it to WT mice after immunization against MOG<sub>35-55</sub> peptide. Dantrolene treated mice developed a strongly attenuated EAE course (**Fig. 3.40**). In fact, the reduction of clinical symptoms was greater than observed in the respective KO chimera experiments. This may be due cumulative effect of inhibition of RyR1 in T cells and RyR3 in astrocytes. Furthermore, in fetal liver chimeric mice a substantial fraction of recipient-derived, and thus *Ryr1*-proficient T cells, may account for a less pronounced EAE ameliorating effect comparing to drug treatment effect. As the dantrolene was applied systemically, effects of this drug on other cells or organs cannot be ruled out. Future experiments using the treatment of *Ryr1*-KO FLCs and *Ryr3* germline KO mice and respective controls with dantrolene should help to clarify the inhibition of which RyR isotype has a dominant role in the therapeutic effect of this drug on the EAE progression.

## 4.6 Conclusion

Our study suggests a putative role for RyRs in MOG<sub>35-55</sub> peptide EAE in two different ways: While the RyR1 isoform is highly expressed in T cells and obviously contributes to T cell activation *in vitro* as well as *in vivo*, Ca<sup>2+</sup> signaling via RyR3 crucially contributes to chemokine production in astrocytes during the onset and acute phase of EAE, thereby mediating T cell and monocyte recruitment to the CNS.

**Fig. 4.1** | Suggested roles of RyR1 and RyR3 during the development of autoimmune diseases of the CNS: While RyR1 contributes to T cell activation in the periphery and/or in the CNS, RyR3 is expressed in astrocytes where it is involved in the production of chemoattractants for T cell and monocyte recruitment.

## 5 Summary

T cell activation requires the elevation of free intracellular  $\text{Ca}^{2+}$ , which is mediated by certain  $\text{Ca}^{2+}$  release channels. During the last years it has become increasingly clear that ryanodine receptors (RyRs) play a crucial role for the generation of intracellular  $\text{Ca}^{2+}$  signals in T cells and thus contribute to T cell activation.

The development of CNS autoimmune diseases like multiple sclerosis (MS) or its animal model experimental autoimmune encephalomyelitis (EAE) relies on the activation of auto-reactive T cells that are directed against CNS antigens. In the present study we addressed the question how RyRs contribute to the development of autoimmune diseases. We found that the RyR1 isoform is expressed in effector, but not in naïve mouse cells. By genetic deletion of the *Ryr1* gene we demonstrated contribution of RyR1 to  $\text{Ca}^{2+}$  signaling and TCR dependent T cell proliferation. This presumably caused the observed EAE attenuation in *Ryr1*<sup>-/-</sup> fetal liver chimeras.

Amelioration of EAE was observed in mice with a whole-body knockout for *Ryr3*. However, in contrast to RyR1, we excluded a major role of *Ryr3* in T cells using chimeric mice and T cell transfer experiments. However, we demonstrated a pivotal role for RyR3 in astrocytes. *Ryr3* deficient astrocytes showed alterations in  $\text{Ca}^{2+}$  signaling and deficits in chemokine production upon inflammatory stimuli *in vitro*, but also during EAE in the inflamed CNS tissue, thus limiting the infiltration of immune cells and CNS histopathology. In addition we showed that pharmacological inhibition of RyRs attenuated EAE disease. In summary, our study provides evidence that RyRs play critical roles during EAE—RyR1 in T cells and RyR3 in astrocytes—and thus may be targets for therapeutic treatment of autoimmune CNS diseases.

## 6 Acknowledgment

First of all, I would like to express my thanks to Prof. Alexander Flügel for giving me the opportunity to work in his lab on this exciting project, and for his support throughout this thesis. Furthermore, I gratefully thank Dr. Dmitri Lodygin for his superb supervision, advice and efficiency. Moreover, I would like to thank the additional members of the examination board, Prof. Hauke Werner, Prof. Mikael Simons and Prof. Jürgen Wienands for accepting the invitation to my thesis defence talk.

I would like to thank Fred Lühder and Francesca Odoardi for their advice and help of any kind.

Special thanks go to our collaboration partners from the lab of Prof. Andreas Guse in Hamburg, especially Insa Wolf and Björn-Philipp Diercks, for performing calcium imaging. I sincerely thank all the coworkers of Prof. Uwe-Karsten Hanisch (†2015) for teaching me the isolation of glia cells.

I am grateful to all our technicians. Without their help, this work would not be possible. Therefore I thank Adriane Stas, Simon Mole, Nancy Meyer, Simone Hamann, Martina Weig, Birgit Curdt and Brigitte Salzmänn-Aue for their invaluable help throughout this thesis. I also like to thank our animal caretaker Michael Blessmann for his help and good taste in music. I thank Omar Diaz for help with any IT questions. Special thanks go to Cathy Ludwig, our secretary, for her help in any bureaucratic and administrative matters of any kind.

I also want to thank all of my fellow PhDs and anyone else working in the IMSF, present or past, for the nice atmosphere, their (moral) support and friendship. So I thank Alex, Anne, Christian, Corinna, Giuseppe, Iris, Judith, Henrike, Leon, Maïke, Marit, Michael, Moritz, Nadine, Nicola, Stephen (thanks for proofreading!) and Tanja.

Last but not least I would like to thank my family and Julia for their endless patience and support.

# CURRICULUM VITAE

Full name: Manuel von Osten  
Address: Institute for Multiple Sclerosis Research  
Waldweg 33  
37 073 Göttingen  
Phone: +49 551 39 13 344  
Email: manuel.von-osten(at)med.uni-goettingen.de

## Education

2012 – PhD student in the Department of Neuroimmunology,  
Institute for Multiple Sclerosis Research, University  
Medical Center Göttingen & Max-Planck Institute for  
Experimental Medicine under supervision of Prof. Dr.  
Alexander Flügel

2011 – 2012 Scientific coworker, University Medical Center  
Göttingen

2010 – 2011 Scientific coworker, Institute for Pharmacology and  
Toxicology, Biomedical Center, Bonn  
& Bonn International Graduate School of Drug  
Sciences

2004 – 2009 Biology course, University of Cologne; Diploma degree  
Diploma thesis in genetics under supervision of Prof.  
Jonathan Howard, PhD, FRS
