JUN.-PROF. DR. SELVAN DEMIR

Tag der mündlichen Prüfung: 16.12.2016

A great time.

This thesis originated in the time between January 2013 and October 2016 at the Institute for Inorganic Chemistry of the Georg August Universität Göttingen.

I am deeply indebted to my supervisor

Prof. Dr. Sven Schneider

Thank you for offering me this fascinating research project, for your help, continual support and motivation also in hard times, for your trust in me and my skills, the many opportunities to meet researchers on conferences all over the world, the very good research equipment and the many inspiring discussions.

I also want to express my gratitude to

Prof. Dr. Franc Meyer

For taking the part of my second supervisor and being referee for my thesis.

Furthermore, my special thanks go to:

The whole examination committee for their time and *Dr. Markus Scheibel* and *Markus Kinauer* for proofreading my thesis.

My current and former colleagues of the Schneider group *Dr. Markus Finger*, *Dr. Christian Würtele*, *Dr. "Vivi" Lagaditis*, *Dr. Gleb Silantjev*, *Dr. Ekaterina Yuzik-Klimova*, *Dr. Suresh Raju*, *Josh Abbenseth*, *Florian Schendzielorz*, *Jan Gerkens*, *Felix Schneck*, *Arne Glüer*, *Christoph Schiwiek*, *Bastian Schluschaß*, *Christian Volkmann*, *Josef Matys*, *Daniel Delony* and *Kai-Sebastian Kopp*. Especially, I would like to thank my labmates *Dr. Markus Scheibel* and *Markus Kinauer* for the great and pleasant time.

Dr. Christian Würtele and *Christian Volkmann* for their efforts in X-ray diffraction with my often "challenging" crystals and *Dr. Markus Finger* for all DFT calculations.

I also want to thank my students for practical courses *Marvin Böhm*, *Kunal Kureja*, *Nicolas Sauermann* and *Josef Matys*. My special thanks go to my bachelor students *Rahel Ziemer* and *Florian Tondock*.

The members of the analytical laboratories and the mass department for their efforts in measuring highly air sensitive samples.

I further want to acknowledge *Dalila Griffin* and *Dr. Claudia Stückl* for their help and support with administrative affairs.

Sandra Krick Calderón, *Konstantin Weber*, *Philipp Rodehuts Kors*, *Hanno Dietrich*, *Matthias Franke* and *Marcel Holler* for the awesome time from the first semester until now. Thank you for staying friends all over the years.

Andrea and *Benjamin Heubach* as well as *Anna Grunert* and all off my friends for your support and understanding.

Dr. Markus Scheibel for your caring support, the scientific discussions, for everything I have learned from you and the marvelous time we spend together in the lab and especially beyond.

My family. Thank you for giving me the opportunity to become who I am, your permanent support in every possible way and for always being there for me.

I Introduction

Parts of this chapter were submitted as a review article for publication in “**Topics in Organometallic Chemistry**” of the *Springer* publishing company.

1 Nitrogenase, Haber Bosch and heterogeneous N₂-Splitting

Nitrogen is next to oxygen, hydrogen and carbon one of the main elements found in organic compounds. For thousands of years, there was basically only one way to convert the relatively inert atmospheric N₂, which constitutes about 80% in air, into organic molecules. Certain microbial organisms are able to transform N₂ into ammonia via the enzyme nitrogenase. The most active form of this enzyme, the Fe-Mo nitrogenase has been intensively studied and the active site (FeMo-co) for N₂ fixation was structurally characterized in 1992,^[1] as a cluster of seven iron and one molybdenum atom bridged by ten sulfurs. In the center, one light atom was found (C, N or O) ^[2] whose identity was revealed as interstitial carbide not before 2011.^[3,4] There exist two proposed mechanisms for N₂ reduction by nitrogenase: The alternating pathway, entailing subsequent protonation and reduction of both nitrogen atoms until the N-N bond is split and the distal pathway, comprising first full reduction and protonation of the β-nitrogen to yield NH₃ and an intermediate metal nitride M≡N.^[5,6]

As the world's population was growing, the interest in synthetic nitrogen fixation for production of artificial fertilizers led to the development of one of the most important technical applications. In 1910, *Fritz Haber* discovered a synthesis for NH₃ out of its elements^[7], which was brought on an industrial scale by *Carl Bosch* only a few years later and which is now called the *Haber-Bosch* process.^[8]

Magnetite Fe₃O₄ with additives of aluminum, potassium and calcium oxides is commonly used as heterogeneous catalyst in this reaction. The accepted mechanism proceeds over initial dissociative chemisorption of N₂ on the catalyst surface into nitrides, which also represents the rate limiting step of the reaction. These surface bound nitrides react with adsorbed H atoms to form stepwise three N-H bonds and release ammonia. As chemisorption of N₂ is very slow, high temperatures and

pressures (300-500°C, 200-300 bar) are needed in this process to obtain good yields, although the actual transformation of N₂ to NH₃ is exothermic.^[9] The tremendous demand of NH₃ for the agricultural and chemical industry, about 200 million tons are produced annually, as well as the harsh reaction conditions lead to a global energy consumption of about 1-3%. Besides, the process is responsible for 1.6% of the global CO₂ emissions, especially attributed to the steam reforming for H₂ production.^[10] Alternative nitrogen fixation systems are therefore of high interest. Especially electrochemical approaches are intensively studied, but suffer from comparatively low selectivities (H₂ evolution) and energy efficiency.^[9,10]

About 20% of ammonia produced by the *Haber-Bosch* process is converted into organic molecules including amino acids, nitriles, amides, and ureas.^[11,12] Another approach in N₂ chemistry is trying to circumvent NH₃ (and therefore H₂ production) but directly produce these molecules by nitrogen functionalization in homogenous systems. Examples for such reaction are still scarce though.^[13,14]

The functionalization of N₂ thus represents a major challenge for today's chemistry. This work will focus on initial N₂ cleavage in homogenous systems in analogy to the *Haber-Bosch* process in order to transform nitrogen in chemically and biologically more valuable compounds.

2 The beginnings of molecular N₂ chemistry

Vol'pin and *Shur* were the first to study nitrogen fixation with transition metals under mild conditions in the mid 1960s.^[15] Inspired by the nitrogenase, which is fixing dinitrogen rapidly under ambient conditions under participation of transition metals - even though the characteristics of the active site and its mode of action were completely unclear to that time - the authors stated, activation of N₂ may be possible due to coordination of dinitrogen to a metal center. π -Transition metal complexes with olefins or acetylene were known, so in the presence of a coordinatively unsaturated metal complex, also complexation by N₂ was thought to be possible. To test their assumption, they reacted metal halide salts (TiCl₄, FeCl₃, WCl₆ and MoCl₅) with hydrogen delivering reducing agents such as LiAlH₄, grignard reagents, lithium or aluminum alkyls under N₂ pressure (150 atm) and observed ammonia formation in

9-25% yield after workup with dilute acids. Yields of 70% are reported even under atmospheric N₂ pressure for the reaction of Cp₂TiCl₂ (Cp = cyclopentadienyl) with ethylmagnesium bromide, illustrating the huge influence of the ligand sphere. However, these systems remain ill-defined and no intermediate could be structurally characterized.^[16-18]

The first isolated transition metal complex containing coordinated N₂ was reported in 1965 by *Allen and Senoff* (Figure 1) and stimulated the discovery of hundreds of other dinitrogen complexes.^[19] Usually the coordinated dinitrogen is not bound very strongly to the metal center and is easily replaced by several other ligands. This is why the discoverers of the first N₂ complex brought into question whether such N₂ complexes even play a part

Figure 1: First isolated N₂-complex.

in the enzymatic nitrogen fixation observed for the nitrogenase.^[20,21] Hope sparked again, when the first successful functionalization of N₂ with a well-defined metal complex was carried out by the group of *Chatt* in 1972. Protonation of *trans*-[M(N₂)₂(dppe)₂] (M = Mo or W, dppe = Ph₂PCH₂CH₂PPh₂) with hydrochloric acid yields [MX₂(N₂H₂)(dppe)₂], where one N₂ ligand is reduced to N₂H₂.^[22] Additionally, *Chatt* observed the first nitrogen-carbon bond formation with N₂ derived nitrogen by

Scheme 1: *Chatt cycle* for catalytic NH₃ production.

addition of acyl chlorides to N₂ complexes in which however the N-N bond in the resulting M(Cl)(-N=N-COR) complex is still intact.^[23,24] Stoichiometric conversion of coordinated N₂ into ammonia and/or hydrazine under mild reaction conditions could be accomplished in molybdenum and tungsten based complexes bearing phosphines as ligands. This reaction has been intensively studied and led to the formulation of the so called "*Chatt cycle*" for a proposed catalytic nitrogen fixation reaction (Scheme 1).^[25-30] However, it took more than 20 years for the development of a defined homogenous and well-characterized catalytic system for N₂ reduction to ammonia.

3 Catalytic systems for ammonia formation

In 2003, the group of *Schrock* reported the first homogenous catalyst, which fulfilled the whole six electron - six proton reduction of N_2 to NH_3 (Scheme 2).^[31] The triamidoamine Mo complex coordinates N_2 and cleaves the NN bond upon alternating steps of protonation and reduction, similar to the *Chatt cycle*. Decamethylchromocene ($CrCp^*_2$) acts as reducing agent together with lutidinium tetrakis[3,5-bis(trifluoromethyl)phenyl]borate ([LutH]Bar^F₄) as proton source. The system is able to generate 8 equivalents of ammonia based on the catalyst. An impressive number of

Scheme 2: Schrock's catalyst and reaction conditions for NH_3 production.

intermediates in the catalytic cycle has been isolated and characterized, giving detailed insights into the mechanism of the catalytic nitrogen fixation, which is also supported by theoretical investigations.^[30-35] In contrast to the *Chatt cycle*, where Mo(0) to Mo(IV) oxidation states are assumed, in the *Schrock cycle* the physiologically more relevant oxidation states Mo(III) to Mo(VI) are passed through. This is also related to the enzyme nitrogenase, where a similar mechanism is proposed for nitrogen fixation.

In 2011, the group of *Nishibayashi* published a homogenous catalyst, which initially evolved 23 equivalents of ammonia (Scheme 3).^[36,37] The dinitrogen bridged dimolybdenum complex with PNP'-pincer ligand (PNP' = 2,6-bis(di-*tert*-butylphosphinomethyl)pyridine) is reduced with cobaltocene as reducing agent and lutidinium triflate ([LutH]OTf) as proton source. Modifications of the pincer ligand strongly affected the catalytic reactivity of the complex.

Scheme 3: Nishibayashi's catalyst and reactions conditions for NH_3 production.

Smaller substituents on the PNP ligand gave only an about stoichiometric amount of NH_3 . Furthermore, electron donating groups in the pyridyl ring were found to facilitate the most difficult step according to DFT calculations, the first protonation of N_2 to a $-NNH$ unit.^[38] The proposed mechanism does not involve the fragmentation of the molybdenum dimer into monomers as it has been suggested formerly.^[39,40] Instead, the $\mu-N_2$ bridged dimolybdenum core is believed to play an important role. Similar to the *Schrock cycle*, the terminal nitrogen is then reduced and protonated to

release one molecule of ammonia under formation of a terminal nitrido complex. Subsequent protonation and reduction then converts the nitrido moiety into the second equivalent of ammonia.^[41,42] In an attempt to enhance the stability of the catalyst towards protonation, a new triphosphine PPP pincer ligand (PPP = bis(*tert*-butyl-phosphinoethyl)phenylphosphine) has been developed recently.^[43] Unexpectedly, already the starting compound [(PPP)MoCl₃] showed catalytic activity for nitrogen fixation, which is not the case in the PNP system. The cationic nitrido complex [(PPP)Mo(N)Cl]⁺ generated under improved reaction conditions 63 equivalents of ammonia, the so far highest catalytic activity ever observed for a defined homogenous catalyst system. A similar mechanism as for the PNP system is proposed, but no intermediates could be observed so far.^[43]

Besides molybdenum, iron is one of the most studied transition metals related to nitrogen fixation. In the Haber Bosch process as well as in the nitrogenase, iron centers are involved in the NN splitting process. First attempts to nitrogen fixation with iron reach back into the 1960s, when *Vol'pin* and *Shur*, reported ammonia formation in 9% yield.^[15] The first well-defined catalytic system for nitrogen fixation using iron has been developed by the group of *Peters* in 2013 (Scheme 4).^[44] The complex [(TPB)Fe]BAr^F₄ (TPB = tris[2-(*di-iso*-propyl-phosphanyl)phenyl]borane) can be reduced with excess Na/Hg and crown-ether under N₂ atmosphere to the iron(-1) compound [Na(12-C-4)₂][(TPB)Fe(N₂)]. Both complexes turned out to be catalytically active, with the latter achieving slightly higher turn overs. Catalysis experiments are performed by sequential addition of an excess amount of HBar^F₄ as proton source and an excess amount of KC₈ as reductant to the catalyst solution at -78°C and generated 6.2 and 8.5 equivalents of NH₃, respectively, based on the aforementioned amount of catalyst. The major side reaction is formation of H₂ from the proton source under the highly reducing conditions. Dihydrogen acts as catalyst poison, as it reacts with neutral [(TPB)Fe(N₂)] to the adduct [(TPB)(μ-H)Fe(N₂)(H)], which is only little active in nitrogen fixation.^[44,45] Although some other Fe systems have been found to catalyze the reduction of N₂ into ammonia, *Peters'* complex is still the most active.^[37,46]

Scheme 4: *Peters'* catalyst and reaction conditions for NH₃ production.

All catalytic systems until now have in common that they rely on strong reducing agents and acids as proton source.

4 Towards N-N-bond cleavage: Bonding in N₂-complexes

4.1 General considerations

The lacking dipole moment and the high bond dissociation energy (941 kJ mol⁻¹) account for dinitrogen as a kinetically and thermodynamically very stable molecule. The reason for its exceptional stability lies in the effective overlap of the s- and p-orbitals of the two nitrogen atoms to form very low lying, completely filled σ - and π -molecular orbitals. The energy gap from the HOMO (highest occupied molecular orbital) to the LUMO (lowest unoccupied molecular orbital) is substantial, leading to both difficult reduction and oxidation. Hence, the ionization energy of N₂ is approximately the same as for argon (15.58 eV and 15.75 eV respectively). In addition, also the proton and electron affinities are low (5.1 eV and -1.9 eV respectively).^[21,47,48] Considering the cleavage of the NN bond, dissociation of the first of the three bonds in dinitrogen is the most difficult, requiring about half of the total triple bond energy (410 kJ mol⁻¹) and resulting in a high kinetic barrier. This is in contrast to acetylene for example, which first bond is a lot more easy to brake (222 kJ mol⁻¹), although the total triple bond energy (962 kJ mol⁻¹) is even stronger than for N₂.^[49]

The way N₂ is bound to a metal center strongly depends on the metal, its oxidation state and the ligand environment. In principle, there have been observed 4 coordination modes: (1) mononuclear end-on, (2) Dinuclear end-on, (3) Dinuclear side-on and (4) Dinuclear side-on-end-on (Figure 2).

Figure 2: Different bonding motifs in N₂ complexes.

The different coordination modes generally show a different kind of activation of the N-N bond. The term “activation” herein describes the degree of elongation of the N-N bond length combined with the reduction of its stretching frequency compared to free N₂ (1.10 Å and 2331 cm⁻¹).^[50,51] In general, activation in mononuclear end-on N₂ complexes (η^1 -N₂) turned out to be rather low. The vast majority of such metal complexes, especially for the later transition metals, belongs to this type. The metal dinitrogen bond can be described as a combination of overlap of the filled σ -orbitals

of dinitrogen with suitably empty metal d-orbitals forming a σ -bond and π -backbonding from filled metal d-orbitals into empty π^* -orbitals of dinitrogen (Figure 3). In consequence, the N-N bond becomes weaker upon coordination to a metal center and activation increases similar to isoelectronic CO complexes. But compared to the latter, N₂ is both a much poorer σ -donor and π -acceptor, mainly because the energy of HOMO and LUMO orbitals usually simply does not match very well the energy of the metal's d-orbitals.^[21] These reduced interactions decrease the stability of N₂ complexes and lead to the main reaction observed for this kind of complexes: dissociation and replacement of the N₂ ligand.

Figure 3: End-on metal-N₂ bonding: σ -bonding from N₂ to the metal and two π -bonding interactions from the metal to N₂.

In dinuclear complexes, where the N₂ moiety is bridging two metal centers, activation can become higher. As π -backbonding from the metal to dinitrogen accounts mostly for increased M-N strength, the metal must be in a low oxidation state and possess a rather high electron density. Highly reducing early transition metals can donate their electrons more easily into the empty π^* -orbitals of N₂, resulting in stronger activation. Concerning, the splitting of the NN-bond forming nitrides, the metal center must be capable of donating enough electrons to provide all 6 electrons required for complete nitrogen reduction. An initial low oxidation state of the metal is therefore beneficial and the use of multiple metal centers, where the electron count is distributed on all metals, seems reasonable. As dinuclear coordination is also essential for the metal mediated cleavage of the NN-bond into nitrido complexes, bonding in these complexes will therefore be discussed in more detail in the following sections.

4.2 End-on bridging N₂

N₂ end-on bridging, M-(μ-η¹-η¹-N₂)-M, is the most frequently observed coordination mode for dinuclear N₂ complexes. The M-N≡N-M unit is more or less linear to allow for efficient orbital overlap. In general, N₂ gets activated upon η¹-coordination to the first metal center, so electron density in the π* orbitals increases, rendering the coordinated molecule a better base for another metal center. Thermodynamics also play a role, as formation of strong multiple M-N-bonds is facilitated by further reduction from the other metal, creating electron delocalization over the whole M-N-N-M unit.^[52] In principle, such a complex can be represented in three different resonance structures, with differing modes of activation: (1) N₂ is only coordinatively bound to both metals centers, showing only minor activation. (2) Formal two electron reduction of N₂ to a diazene unit (N₂)²⁻ and (3) formation of a hydrazine derivative (N₂)⁴⁻, if the metals are capable of donating two electrons each to the N₂ moiety, leading to simultaneous cleavage of both π-bonds of N₂ (Figure 4). Following this approach, further reduction would then lead to N-N-bond cleavage and form metal nitrides.^[53]

Figure 4: Different types of N₂ activation in end-on coordinated dinuclear complexes.

In this very simplistic view, one might think, the more electrons, the more the NN bond is weakened and the easier N₂ is split. This expectation is however only in parts true. For example, the complex [(NH₃)₅Ru-N₂-Ru(NH₃)₅]⁴⁺ with a d⁶ electron configuration for both metal centers, shows only little activation of the N₂ unit (Figure 5) and only minor differences compared to the mononuclear analogue [(NH₃)₅RuN₂]²⁺, although two metals are involved in bonding. Moreover, a rather strong activation is observed for complex [(PMe₂Ph)₄ClRe-N₂-MoCl₄(OMe)] with a d⁶ and d¹ electron configuration for Re and Mo respectively.

Figure 5: Different degree of activation in N₂ complexes.^[21]

This observation can be rationalized by considering the molecular orbitals of a M-N-N-M moiety, as first stated by Gray^[54] and Chatt^[55] and reviewed by Sellmann.^[21] In a qualitative scheme, four center molecular orbitals are obtained by linear combination

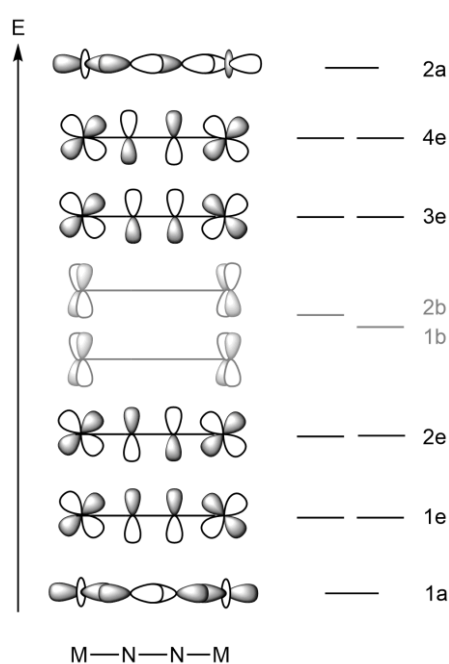

Figure 6: MO scheme for end-on coordinated dinuclear N₂ complexes.

of the metal's d-orbitals with the proper p-orbitals of dinitrogen (Figure 6). The z-axis is determined along the σ -bond (1a), giving rise to four sets of π -orbitals, whose energy is increasing with the number of nodal planes (1e – 4e). For each linear combination, there exist two degenerate molecular orbitals, one for the $Md_{xz}-Np_x-Np_x-Md_{xz}$ and one for the $Md_{yz}-Np_y-Np_y-Md_{yz}$ orbitals (90° rotated). Additionally, in fourfold geometry, there are two δ -orbitals, formed from the Md_{xy} -orbitals, which are essentially non-bonding (1b and 2b). In a threefold geometry, these orbitals are not available due to interactions with the ancillary ligands. The strength of M-N and N-N is determined by the occupancy of all of these molecular orbitals. Filling in 6-electrons from N₂ leads to full occupation of the 1a σ - and the 1e π -level, which are all bonding. Further electrons occupy the 2e level, which weakens the N-N bond.

Occupation of the 1b and 2b levels, if available, does not contribute significantly to N₂ binding. The 12 electrons from $[(NH_3)_5Ru-N_2-Ru(NH_3)_5]^{4+}$ however fill the orbitals until the 3e level, which is N-N-bonding again, producing in total three N-N-bonding orbitals (5 bonding vs. 2 antibonding MOs). This reflects the minor difference in N₂ activation compared to the mononuclear complex $[(NH_3)_5RuN_2]^{2+}$. With electron poorer metals (3e level vacant) N₂ bond activation increases, as it is in $[(PMe_2Ph)_4ClRe-N_2-MoCl_4(OMe)]$, which only has 7 d-electrons. Going further to the left in the periodic table, activation increases, as even δ -orbitals become empty. The group of *Gambarotta* synthesized the titanium dimer $\{[(Me_3Si)_2NTiCl(TMEDA)]_2(\mu-\eta^1-\eta^1-N_2)\}$, which shows strong N₂ activation, in agreement with a formal 4 electron reduction to a $(N_2)^{4-}$ unit (Figure 7).^[56-58] However, factors influencing the activation of N₂ are not only derived from the electron count in this simplified molecular orbital scheme. The complex $\{[(Cp^*Ti(\eta^6-C_5H_4CR_2))]_2(\mu-\eta^1-\eta^1-N_2)\}$ (R = *p*-tolyl) shows a considerable smaller activation, although for titanium(I) according to the MO scheme δ -orbitals should be occupied (Figure 7).^[59] DFT calculations on these complexes reveal a significant influence of the ligand sphere.^[57] Electrons of titanium are involved in π -backbonding to the fulvene ligands, preventing them from interactions with the π^* -orbitals of N₂. Although titanium(II) is less electron rich, the ligand sphere allows more electrons to be available for N₂ reduction. Accordingly, the activation of N₂ can also be correlated to the donor/acceptor properties of the ligand environment.

Figure 7: Ti(II) (left) complex exhibiting strong N₂ activation and Ti(I) complexes with significantly smaller activation.

Another example for the ligand influence on the orbital disposition in dinuclear complexes is very well illustrated in the recent work of *Chirik*.^[60] His group was able to isolate five terpyridine molybdenum dinitrogen complexes $[\{(\text{PhTpy})(\text{PPh}_2\text{Me})_2\text{Mo}\}_2(\mu\text{-}\eta^1\text{-}\eta^1\text{-N}_2)][\text{BAR}^{\text{F}_4}]_n$, which only vary by oxidation state ($n = 0, 1, 2, 3, 4$) (Scheme 5).^[60] The dicationic complex $[\{(\text{PhTpy})(\text{PPh}_2\text{Me})_2\text{Mo}\}_2(\mu\text{-}\eta^1\text{-}\eta^1\text{-N}_2)][\text{BAR}^{\text{F}_4}]_2$ displays parameters in agreement with a $[\text{N}_2]^{2-}$ bridge. DFT calculations describe the HOMO as one of the 3e levels. Because of π -interactions of only one of the MOs in one level with the terpyridine ligand, the 3e orbitals are not degenerate any more, resulting in a diamagnetic complex. Additionally, the LUMO is calculated to be mainly ligand centered and NN antibonding in character. Intriguingly, isolation of the oxidized and the doubly oxidized form of the complex, as well as the reduced and the doubly reduced form has been achieved. Oxidation leads to a weakening of the N-N bond as the electron is removed from the N-N bonding 3e orbital. Further oxidation leads to a slightly weaker N-N bond and formation of a compound with electronic triplet ground state. Reduction of the starting complex by one electron leads to a paramagnetic $S = \frac{1}{2}$ compound, where the electron is located mainly on the terpyridine ligand. Even the second electron of further reduction can be stored in the terpyridine ligand, forming neutral, diamagnetic $[\{(\text{PhTpy})(\text{PPh}_2\text{Me})_2\text{Mo}\}_2(\mu\text{-}\eta^1\text{-}\eta^1\text{-N}_2)]$. So the ligand does not only influence N₂ activation, it can also be redox active and store additional reducing equivalents, enabling such a system as promising platform for N₂ reduction.

Scheme 5: Transformations of $[\{(PhTpyp)(PPh_2Me)_2Mo\}_2(\mu-\eta^1-\eta^1-N_2)][BArF_4]_n$ ($n = 0-4$) by one electron redox reactions.

The influence of the metal in dimeric N₂-bridged complexes has been examined by the group of Sita, who could isolate and characterize a complete series of isostructural cyclopentadienyl/amidinate complexes (Cp*amM)₂(μ-N₂) (am = [N(*i*Pr)C(Me)N(*i*Pr)], M = Ti, Zr, Hf, V, Ta, Nb, Mo, W) (Figure 8).^[61-63] While steric and electronic environment can be held constant, N₂ activation can be monitored as a function of group and row position of the metal and its formal oxidation state and valence electron count. Whereas for Zr and Hf side-on bridged N₂ complexes could be observed, all other metals showed end-on dinitrogen coordination. NN-bond lengths of all isolated complexes are summarized in Table 1.

Table 1: N-N bond distances in (Cp*amM)₂(μ-N₂) complexes.

| Metal | Coordination mode | d(NN) [Å] | reference |
|-------|---|-----------|-----------|
| Ti | (μ-η ¹ -η ¹ -N ₂) | 1.270(2) | [62] |
| Zr* | (μ-η ² -η ² -N ₂) | 1.518(2) | [64] |
| Hf | (μ-η ² -η ² -N ₂) | 1.611(4) | [64] |
| V | (μ-η ¹ -η ¹ -N ₂) | 1.225(2) | [63] |
| Ta | (μ-η ¹ -η ¹ -N ₂) | 1.313(4) | [61] |
| Nb** | (μ-η ¹ -η ¹ -N ₂) | 1.300(3) | [63] |
| Mo | (μ-η ¹ -η ¹ -N ₂) | 1.267(2) | [62] |
| W | (μ-η ¹ -η ¹ -N ₂) | 1.277(8) | [62] |

* Exchange of methyl group in amidinate against NMe₂.

** Exchange of methyl group in amidinate against phenyl.

Figure 8: Sita's isostructural (Cp*amM)₂(μ-N₂) complexes.

The diamagnetic Ti analogue is according to the authors best described as two spin coupled Ti(III,d¹) centers, connected by a [N₂]²⁻ bridge. As Ti possesses a very high fourth ionization potential, further reduction of N₂ is difficult to achieve.^[65] Strongest N₂ activation however is observed for the Zr and Hf analogues, where oxidation to formal +IV is less hindered. Ta and Nb dimers show smaller activation, as the reduction potential is lower for these metals. The niobium complex turned out to be kinetically more unstable though and the (μ-η¹-η¹-N₂)-bridged complex could only be obtained by employing the more bulky phenyl substituent within the amidinate ligand. Least activation is observed for the thermally remarkably robust vanadium complex, comprising two antiferromagnetically coupled V(II, d³) centers. Formal oxidation state assignment is supported by the fact that N₂ is easily displaced by strong π-acceptor ligands, yielding neutral CpamV^{II}(CNR)₂. The diamagnetic group 6 analogues are again in agreement with decreasing reduction potential and show a slightly reduced activation of the bridged N₂, compared to Nb and Ta. In contrast to the latter complexes however, group 6 compounds exhibit easy displacement of the N₂ ligand by strong π-acceptors such as CO or isonitriles, giving rise to a M(II, d⁴) formulation.

These results imply that a simple consideration of the electron count in the MO scheme in Figure 6, is only half of the truth. The relative energies of the orbitals, their spin population and the ligand environment are influencing the MOs and are therefore rendering the picture of N₂ complexes clearly more complicated.

4.3 Side-on bridging N₂

The side-on coordination mode is not as usual as the end-on one in dinuclear N₂ complexes.^[50,66,67] The earliest mention of a such a complex was in 1970, when isotopically labeled Ru complexes [(NH₃)₅Ru(¹⁴N¹⁵N)]Br₂ and [(NH₃)₅Ru(¹⁵N¹⁴N)]Br₂ were shown to interconvert over time.^[68] The rates of isomerization turned out to be faster than simple dissociation and recoordination of N₂, suggesting an intramolecular rearrangement through side-on coordination. The first structurally characterized side-on N₂ complex was reported in 1973 for a polynuclear nickel-lithium compound.^[69,70] For f-block metals side-on coordination is more common, since the group of *Evans* characterized the first one in 1988.^[71] The (Cp*₂Sm)₂(μ-η²-η²-N₂) complex contains basically no activated N₂, displayed by its short N-N bond length of d(NN) = 1.088(12) Å and the fact, that N₂ is easily lost upon exposure to vacuum. In contrast, also very strong N₂ activation can be observed in side-on

bridging N₂ as illustrated for the complex ([PNP]ZrCl)₂(μ-η²-η²-N₂) ([PNP] = *i*Pr₂PCH₂SiMe₂)₂N), which displays an N-N bond length of $d(\text{NN}) = 1.548(7) \text{ \AA}$ in a planar Zr-N₂-Zr array.^[72] Today, there exist a number of side-on bound dinitrogen complexes, mostly with early transition metals and f-block elements. However, the end-on coordination mode is certainly the most common.^[66] The question that arises now is what makes the difference between these two binding motifs.

To describe the electronic structure in N₂ side-on bridging complexes, considering the molecular orbital scheme as depicted for the end-on bridging mode (Figure 6), is recommended. However, bonding in side-on N₂ complexes is more sophisticated, since N₂ can be lifted out of the M-M plane or the metals can be twisted against each other due to ligand constraints. In a very simplistic picture, there exist a π (and π^*) symmetric MO, having M-N bonding (and antibonding) and N-N antibonding character (Figure 9). These are generated out of d_{yz} orbitals of the metals with one π^* orbital of dinitrogen. Similarly, there are two basically non-bonding MO combinations out of metal orbitals d_{xz} . But instead of a second π -bond created in the end-on coordination mode, only a δ -bond (and δ^* -bond) with M-N bonding (and M-N antibonding) and N-N antibonding character

Figure 9: MO scheme for side-on coordinated dinuclear N₂ complexes.

between the d_{xy} and the second π^* orbital of N₂ can be formed, resulting in a somehow weaker stabilization. Furthermore, the N-N σ -bond is non-bonding (σ_N), as well as the N-N bonding π -orbital formed of p_x orbitals of N₂. In principle, the p_z orbitals for the N-N bonding combination can form a bonding interaction with the respective metal orbitals, but calculations consider these π -donor interactions to be quite small, hence they are neglected in the MO scheme.^[73] Compared to end-on bridged N₂ complexes, involving two M-N π -bonds, in the side-on bridging mode, there is only one π - and one δ -bond. As the latter should have less orbital overlap, it should be less stabilized. Hence, the end-on bridging mode usually is energetically preferred over the side-on mode.^[67]

So what is the reason the side-on mode is formed at all? The most obvious hypothesis therefore would be that there is just no appropriate d-orbital at the metal available for a second back-donation to dinitrogen. Fryzuk investigated this subject and performed calculations on the zirconium complex $\{\text{ZrCl}[\text{N}(\text{SiH}_2\text{CH}_2\text{PH}_2)]\}_2(\mu\text{-}\eta^2\text{-}\eta^2\text{-N}_2)$.^[67] The analysis revealed strong interactions of the amide in the ligand backbone with d-orbitals of the metal, leaving only two d-orbitals for bonding to the dinitrogen ligand. Actually, the amide donates its electrons into the exact orbital necessary for the second π -bonding to dinitrogen, enabling only the side-on coordination mode. Since there were also interactions with the chloride computed, its influence on the coordination mode was investigated chemically by exchange against a Cp ligand and resulted in isolation of the end-on bridging complex $[(\text{PNP})\text{ZrCp}]_2(\mu\text{-}\eta^1\text{-}\eta^1\text{-N}_2)$ (Scheme 6).^[67] This can be rationalized by a modification of the available d-orbitals. A π -orbital of the Cp ligand now overlaps with the d-orbital, which would have been used for δ -bonding in the side-on N₂ complex. Since side-on bonding is inhibited, end-on bonding is engaged and the free electron pair of the amide is “pushed back”. This assumption is supported by the unusually long Zr-N_{amide} distances of 2.306(3) Å and 2.303(3) Å for the Zr moieties in the end-on complex, which are only slightly shorter than in neutral amine-type Zr(IV) adducts.^[74,75]

Scheme 6: Transformation of side-on to end-on dinuclear complexes by ligand exchange.

Of course, steric effects also play a role, as the two metal moieties are certainly closer in the side-on mode compared to the end-on one. That already subtle variation in the steric congestion can change the N₂ coordination mode has been shown by the group of Chirik. The complex $[\text{Cp}^*\text{Zr}(\eta^1\text{-N}_2)]_2(\mu\text{-}\eta^1\text{-}\eta^1\text{-N}_2)$ was reported in 1974 by the Bercaw group.^[76] In 2004, Chirik could demonstrate the formation of a side-on bridged N₂ complex $[(\eta^5\text{-C}_5\text{Me}_4\text{H})\text{Zr}]_2(\mu\text{-}\eta^2\text{-}\eta^2\text{-N}_2)$, only by alteration of the pentamethyl Cp to tetramethyl Cp ligands (Figure 10).^[77] Adding only one methyl group per zirconocene yields again the end-on bridged N₂ complex $[\text{Cp}^*(\text{C}_5\text{Me}_4\text{H})\text{Zr}(\eta^1\text{-N}_2)]_2(\mu\text{-}\eta^1\text{-}\eta^1\text{-N}_2)$.^[78] Thus, only the steric bulk of one methyl group can make the difference in the N₂ coordination mode.^[79,80]

Figure 10: Steric effect on end-on vs side-on N₂ binding.

DFT calculations predict the relative intensity of side-on N₂ bridged isomers to increase down group 4 in the periodic table.^[65] Experimentally, this effect has been

observed for the before mentioned isostructural metal complexes from the group of *Sita* (Table 1). In group 4 complexes of this kind the titanium analogue adopts end-on, whereas the zirconium and hafnium analogues display side-on coordination.^[62] As steric interactions can be critical, the covalent radii for the metals were compared. Here, Zr and Hf possess about the same dimension (1.75 Å), Ti on the other hand is significantly smaller (1.60 Å). It is assumed, that only the larger atoms are able to accommodate the more sterically crowded side-on coordination and the smaller analogues, including the later metals like V (1.53 Å), Nb (1.64 Å) or Mo (1.54 Å), can only adopt the end-on bonding motif with this ligand set.

There also exists an intermediate coordination mode for N₂, the side-on end-on coordination. The complex [(NPN)Ta]₂(μ-H₄) (NPN = (Ph)P(CH₂SiMe₂NPh)₂) was set under an atmosphere of N₂ to generate the complex [(NPN)Ta]₂(μ-H)₂(μ-η¹-η²-N₂), exhibiting a side-on coordination of N₂ to one tantalum center and an end-on coordination to the other (Figure 11).^[81] As the usual coordination mode for tantalum N₂ complexes is end-on, the authors believe, that the bridging hydride in the complex forces the two metal centers in such a close proximity that an end-on binding motif becomes impossible.^[82] The energetic advantage of maintaining the bridging hydrides is believed to prevail over the energy difference to dinuclear end-on coordination.

Figure 11: Side-on end-on N₂ bridged tantalum complex.

5 From N₂-complexes to N₂-splitting

5.1 Dinuclear end-on bridging N₂-complexes

The Cummins system

The year 1995 was a milestone in dinitrogen chemistry. For the first time, the complete scission of the N-N triple bond of N₂ could be observed proceeding over an N₂ bridged dimer into a well-defined terminal nitride. As the group of *Cummins*, tried to recrystallize the sterically demanding triamido molybdenum(III) complex Mo[N(tBu)(Ar)]₃ (Ar = 3,5-C₆H₃Me₂) at -35°C under an atmosphere of N₂, they observed the formation of a new paramagnetic species.^[83] Upon warming to room temperature, the paramagnetism was lost and the formation of a terminal molybdenum(VI) nitride was observed in high yield (76% isolated, Scheme 7). This reaction was not only the first of this kind, it still represents the most intensively studied example of well-defined N₂ splitting. Therefore, in the following, factors influencing N₂ splitting will be described on the basis of this reaction.

Scheme 7: Cleavage of N₂ in terminal nitrides mediated by a triamido molybdenum(III) complex.

After the discovery of the thermally driven N₂ cleavage reaction, following work revealed, that the starting compound lies in equilibrium with an end-on bridged, paramagnetic N₂ complex {Mo[N(tBu)(Ar)]₃}₂(μ-η¹-η¹-N₂). At room temperature however this equilibrium is shifted far towards the monomeric species.^[84] Only minor amounts of nitride could be detected after 12 h in benzene solution and neither the formation of a dimeric species nor a monomeric η¹ terminal N₂ complex is observed at room temperature. Regardless, detailed spectroscopic investigations revealed a rather linear MNNM moiety for the dimeric species, which could also be verified by a crystal structure some years later.^[85] Depending on the crystallization mode, NN

distances of 1.212(2) or 1.217(2) Å [85] could be found together with a Raman shift of $\nu(\text{NN}) = 1630 \text{ cm}^{-1}$ [84], fitting to moderate to strong activation of the coordinated N₂ unit and description as [N₂]²⁻ and formal Mo(IV).^[53] Interestingly, also the mono and doubly oxidized forms of the dimer have been isolated, displaying significantly stronger N₂ activation (Figure 12). Nevertheless, only the neutral species is cleaving the N-N bond. This result indicates that N₂ activation itself is not the only factor governing dinitrogen splitting and strong activation does not necessarily lead to N-N cleavage.

Figure 12: Bond distances, stretching frequencies and number of electron in the MNNM π -system for $\{\text{Mo}[\text{N}(\text{tBu})(\text{Ar})]_3\}_2(\mu\text{-}\eta^1\text{-}\eta^1\text{-N}_2)^{n+}$ ($n=0-2$).

Electronic structure

The electronic structure of the neutral dimeric complex can again be described by a molecular orbital analysis as in chapter 4.2. In threefold symmetry however, no 1b and 2b δ -bonding MOs are available, because these orbitals are involved in bonding to the ancillary ligands. A $(1e_u)^4(1e_g)^4(2e_u)^2(2e_g)^0$ electronic configuration by description with Mulliken labels and therefore 10 π electrons in the MNNM unit, described as $\{\text{MNNM}\}^{10\pi}$, results (Figure 13) and is supported by DFT calculations.^[84,85] Furthermore, the total spin of $S = 1$ is in agreement with SQUID measurements.^[85] The HOMO is described by M-N antibonding and N-N bonding character. Oxidizing the compound removes electrons out of this orbital, resulting in a weakened N-N and strengthened M-N bond in accordance with the experimental data ($\{\text{MNNM}\}^{n\pi}$, $n = 8, 9$).

Figure 13: MO scheme for N₂ cleavage in terminal nitrides out of a Mo(III) dinuclear dimer.

Generation of stable closed shell nitrides requires spin flip from the triplet to the singlet state during the splitting process. The mechanism is believed to proceed via a zigzag transition state (TS), incorporating a further reduced N-N single bond, as it has been calculated by *Morokuma* for the hypothetical complex $[\text{Mo}(\text{NH}_2)_3]_2(\mu\text{-}\eta^1\text{-}\eta^1\text{-N}_2)$.^[86] In this transition state, symmetry is reduced leading to degeneracy of the MO e-levels and enabling spin pairing. N-N cleavage out of the linear dimer leads to an excited state and was computed to be energetically unfavorable.

In addition, the dimer accommodates 10 π - and 6 σ -electrons within the MNNM unit. Two nitrido complexes $\text{N}\equiv\text{Mo}(\text{L})_3$ however require in total 8 π - and 8 σ -electrons. Two electrons must therefore be transferred from π -orbitals in σ -orbitals upon N-N cleavage. In the zigzag TS the doubly occupied $2b_u$ π -orbitals have the appropriate symmetry to be correlated with the energetically higher lying, unoccupied σ -antibonding orbital to form the occupied σ -bonds $1b_u$ in the nitrido complexes. Otherwise, spitting from the linear dimer by simple linear dissociation is symmetry forbidden.^[84] Importantly, also the σ -bonding orbital a_u is lowered in energy ($3b_u$) when reaching the TS, thereby favoring mixing of the σ - and π -symmetric orbitals as their energy difference is decreased. The orbital scheme also indicates that a $\{\text{MNNM}\}^{10\pi}$ system, is essential in this splitting process. Less electrons cause stronger N₂ activation, but splitting is inhibited because no stable nitrido complexes can be formed. This is supported by the isolated oxidized forms of *Cummins'* dimer, containing $\{\text{MNNM}\}^{9\pi}$ and $\{\text{MNNM}\}^{8\pi}$ systems and which do not show N-N cleavage. More electrons however would destabilize the dimer by M-N bond degradation associated with an increase of N-N bond strength. The splitting from the dinitrogen

bridged dimer has been computed to be exothermic by about 20 kcal/mol. Driving force is the formation of strong Mo(VI)≡N triple bonds.

Ligand influence

Besides the electronic configuration, also the steric demand of the ligand system plays an important role. On the one hand, ligands must be small enough to allow for dimer formation. For example, Mo[N(R)Ar]₃ with large substituents R like adamantyl have been shown to be stable towards dinitrogen, presumably because the steric bulk prevents assembling of two such complexes around one molecule of N₂.^[87] On the other hand, too small ligands induce different reactions. For example, the dimerization of Mo(NR₂)₃ (NR₂ = NMe₂, NMeEt, NEt₂) to Mo₂(NR₂)₆ (under N₂ atmosphere) is a well-known reaction (Scheme 8)^[88] and DFT calculations confirm that the main function of the bulky amido ligand is to offer a free coordination site for N₂ binding and prevent dimerization at the same time.^[89]

Scheme 8: Dimerization of Mo(NR₂)₃ with small R-groups.

Besides, also the exchange of the amido ligands against alkoxides ends in the dimerization of the complex without reaction with N₂.^[90,91] By mixing the respective alkoxy nitrido complexes N≡Mo(O^tBu)₃ with Mo(N(R)Ar)₃, the nitride unit is transferred to the latter, yielding N≡Mo(N(R)Ar)₃ and Mo₂(O^tBu)₆ (Scheme 9).^[91] This result suggests facile nitrogen atom transfer and stimulated further investigations.^[90-92] Adding N≡Mo(O^tBu)₃ to Mo(N(R)Ar)₃ under N₂ atmosphere accelerates N₂ splitting significantly, yielding both nitrides. Using N≡Mo(NMe₂)₃ instead of the alkoxy nitride resulted in the isolation of the nitrogen bridged compound (Me₂N)₃Mo(μ-N)Mo[N(R)Ar]₃ (Ar_F = 4-C₆H₄F) as putative intermediate in the N-atom transfer reaction.^[90]

Scheme 9: Nitride transfer by use of sterically less demanding alkoxy-ligands.

Exchanging the R-substituents of the amide in Mo(NR₂)₃ against *iso*-propyl groups results in C-H activation and cyclometalation to Mo(H)(η²-Me₂C=NAr)(N(*i*Pr)Ar)₂.^[93] Unexpectedly, also this compound splits N₂, without observable intermediate, into the paramagnetic single nitrogen bridged species {[Ar(*i*Pr)N]₃Mo}₂(μ-N). In this reaction, the hydride is observed to migrate back to carbon to form three equivalent *iso*-propyl groups again. Molecular orbital considerations predict a {MNM}^{7π} unit with a spin ground state doublet, which is supported by magnetic measurements. The mechanism for formation of the single nitrogen bridged species is thought to proceed via initial N₂ splitting, generating the nitride species N≡Mo(N(*i*Pr)Ar)₃ which then couples with excess Mo(N(*i*Pr)Ar)₃ to the nitrogen bridged dimer (Scheme 10). To

Scheme 10: N₂ cleavage into bridging nitride with cyclometalated Mo(H)(η²-Me₂C=NAr)(N(*i*Pr)Ar)₂.

test this assumption, the nitride complex N≡Mo(N(*i*Pr)Ar)₃ was prepared independently out of N-atom transfer from N≡Cr(O*t*Bu)₃ to cyclometalated Mo(H)(η²-Me₂C=NAr)(N(*i*Pr)Ar)₂ and subsequently reacted with additional cyclometalated complex to show fast coupling to {[Ar(*i*Pr)N]₃Mo}₂(μ-N).^[93] This stands in contrast to the more bulky N≡Mo(N(*t*Bu)Ar)₃, isolable as monomer. Here, such a dimerization is obviously hampered by steric demands. Following calculations confirmed that splitting from {Mo[N(*t*Bu)(Ar)]₃}₂(μ-η¹-η¹-N₂) to the respective terminal nitride is kinetically as well as thermodynamically favored over dimerization to a single nitrogen bridged compound, whereas for smaller ligands (N(*i*Pr)Ar or NMe₂) the formation of {[R₂N]₃Mo}₂(μ-N) is both favored kinetically and thermodynamically.^[94]

A comparison of *Cummins'* end-on dinitrogen bridged dimer with a structurally related complex of the group of *Schrock* [Mo{R'NCH₂CH₂}₃N]₂(μ-η¹-η¹-N₂) (R' = *t*BuMe₂Si) reveals that the story of dinitrogen splitting is not only governed by the number of electrons and the steric demand of the ligand.^[84,95,96] Both complexes contain the same electron count, formal oxidation and spin state and display similar structural parameters. *Schrock's* dimer also

Scheme 11: Comparison of *Schrock's* triamidoamine Mo(III) and *Cummins'* triamido Mo(III) N₂ dimers towards N₂ cleavage.

contains three amido ligands, but a coordination number of 5 with an amine in trans-position to N₂. Besides, electropositive silicon substituents at the amide should have an influence on the donor capabilities. The intriguing difference between these two compounds is that *Cummins'* complex splits N₂ thermally into nitrides and *Schrock's* complex does not (Scheme 11). Calculations on a simplified model complex predict the splitting to be endothermic for the latter complex and exothermic for the former.^[86] This result is attributed to the trans-ligand in *Schrock's* dimer, which as σ-donor transfers electron density to the metal and therefore weakens the M-N₂ bond. In the MO scheme (Figure 13), this influence can be depicted by lifting the σ-bonding orbital a_u in energy. Hence, mixing between this orbital and the π-symmetric orbital 2b_u in the TS is hampered, because the energy difference is too large. This effect renders the whole splitting mechanism thermodynamically and kinetically unfavorable.

Another reason might be the steric strain imposed by the triamidoamine ligand. Calculations of the group of *Stranger* indicate that rotation of one of the amido ligands at each metal center from the trigonal symmetry in such a way that the NC₂ plane stands orthogonal to the MNNM unit leads to stronger π-backdonation from the metal to N₂ and enhanced N₂ activation, as the electron density at the metal is increased (Scheme 13). This effect is accompanied by a stabilization of the singlet state over the triplet state for the dimer, because the degeneracy of the HOMO is lifted and already results in a bent structure.^[97,98] This stands in contrast to the experimentally observed structure and magnetization of the isolated dimer, but the computed results resemble the presumed zigzag transition state.^[85] Ligand rotation during the splitting process might be involved. Furthermore, considering N-N cleavage with the less bulky complex Mo(N(*i*Pr)Ar)₃, dinitrogen splitting is faster and an intermediate could not be observed. Splitting might be accelerated from expected [Mo(N(*i*Pr)Ar)₃]₂(μ-η¹-η¹-N₂), as ligand rotation of *iso*-propyl groups is easier than in the respective *tert*-butyl analogues.^[85,98]

Scheme 12: Scheme 13: Rotation of one NR₂ group at each Mo center.

DFT calculations revealed, that π -donors in the ancillary ligands not only lead to stronger N₂ activation, but also to a more exothermic splitting reaction.^[86,97] Consequently, N₂ splitting with complexes exhibiting no or weak π -donor ligands should be more difficult. In 2001, *Floriani* and coworkers synthesized the molybdenum dimer [(Mes)₃Mo]₂(μ - η^1 - η^1 -N₂) (Mes = 2,4,6-Me₃C₆H₂).^[99] This complex displays similarities with the above described system of *Cummins*. Molybdenum is again 4 coordinate, paramagnetic and in the same formal oxidation state, but the mesityl-ligands are no π -donors anymore and the steric bulk is smaller. Importantly, this dimer is thermally stable (refluxing benzene) and does not cleave N₂ over time. However, dinitrogen can be split in this system by photolysis, which will be discussed in chapter 6.4.

Scheme 14: Synthesis of thermally stable N₂-bridged Mo dimer by *Floriani*.^[99]

Photolysis of N₂-bridged dimer

Bulk irradiation of the N₂ bridged dimer [(Ar(*t*Bu)N)₃Mo]₂(μ -N₂) with visible light ($\lambda \geq 480$ nm) at -78°C to exclude thermal decomposition, produced an about 1:1 mixture of N \equiv Mo[N(*t*Bu)Ar]₃ and Mo[N(*t*Bu)Ar]₃, presumably under loss of 0.5 equivalents of N₂ due to stoichiometry (Scheme 15). As loss of N₂ from the dimeric complex has not been observed before, it is most likely due to an electronic excited state. Formation of the nitrido complex resembles thermal N₂ cleavage. Frequency resolved pump-probe spectroscopy was performed in the group of *Blank* to get more detailed information about the photochemical mechanism.^[100] It turned out photoexcitation at 2.3 eV creates a very short lived excited triplet state, which relaxes through internal conversion in 300 fs to the ground state with subsequent vibrational cooling in subpicoseconds in competition with Mo-N₂ bond dissociation. Coupling to structural distortions facilitates the rapid internal conversion and assists the transition to the singlet state, giving propensity to N-N cleavage.

Scheme 15: Competition of N-N and M-N bond cleavage upon photolysis of $\{\text{Mo}[\text{N}(\text{tBu})(\text{Ar})]_3\}_2(\mu\text{-}\eta^1\text{-}\eta^1\text{-N}_2)$.

These structural distortions have also been found in theoretical examinations on photochemical activation of stable, linear $\mu\text{-N}_2$ complexes ($\text{M} = \text{Fe}, \text{Ru}$) in the group of *Reiher*. The authors suggest population of antibonding π^* orbitals of N_2 upon photochemical excitation resulting in a bent diazenido like structure in the first excited state.^[101] This resembles the zigzag transition state, proposed for *Cummins* splitting mechanism and is in agreement with the observation of terminal nitrides as products of N_2 splitting. Qualitatively, the formation of $\text{Mo}[\text{N}(\text{tBu})\text{Ar}]_3$ together with N_2 can be explained by excitation of electrons in $2e_u$ orbitals (Figure 13). Therefore, the M-N bond is weakened with simultaneous strengthening of the N-N bond, which leads to release of N_2 .

Intermediate Trapping

N_2 Splitting from $\text{Mo}[\text{N}(\text{tBu})\text{Ar}]_3$ to the terminal nitride turned out to be redox-catalyzed. In the presence of Na/Hg , the reaction is significantly accelerated.^[87] By controlling the reaction parameters, the reduced compound $\text{Na}[(\text{N}_2)\text{Mo}(\text{N}(\text{tBu})\text{Ar})_3]$, formally a $\text{Mo}(\text{II})$ species, could be isolated, containing linearly bound and slightly activated N_2 . Since the starting material $\text{Mo}[\text{N}(\text{tBu})\text{Ar}]_3$ is not reduced by Na/Hg , dinitrogen coordination is considered to be the very first step in the cleavage mechanism. The monoanionic compound then presumably reacts with remaining $\text{Mo}[\text{N}(\text{tBu})\text{Ar}]_3$ to an anionic N_2 bridged dimer, which reduces again neutral $(\text{N}_2)\text{Mo}(\text{N}(\text{tBu})\text{Ar})_3$ under generation of the neutral dimer, which is known to split the N-N bond. Oxidation of the trapped anionic complex $[(\text{N}_2)\text{Mo}(\text{N}(\text{tBu})\text{Ar})_3]^-$ does not produce the neutral compound, but deliberates N_2 instantaneously to yield the starting material $\text{Mo}[\text{N}(\text{tBu})\text{Ar}]_3$. In contrast, the related isoelectronic complex $[(\text{Me}_3\text{SiNCH}_2\text{CH}_2)_3\text{N}]\text{Mo}(\text{N}_2)$ with triamidoamine ligand could be prepared by oxidation of $\{[(\text{Me}_3\text{SiNCH}_2\text{CH}_2)_3\text{N}]\text{Mo}(\text{N}_2)\}_2\text{-Mg}(\text{THF})_2$ in the group of *Schrock*.^[102,103] The monomeric complex was structurally characterized and turned out to be moderately stable. Apparently, the apical amine donor in *Schrock's* complex combined with the more reducing silyl-amides in the ancillary ligand increase the electron density at the metal in such an extent that N_2 end-on binding becomes more

stable. The anionic complex $[(N_2)Mo(N(tBu)Ar)_3]^-$ can be functionalized with electrophiles such as methyl triflate (MeOTf), methyl tosylate (MeOTs) or Me₃SiCl to form N_β-E (E = Me, SiMe₃) bonds. With MeOTf even a second methylation to cationic $[(N(tBu)Ar)_3Mo-NNMe_2]OTf$ is possible (Scheme 16).

Scheme 16: Formation of mononuclear end-on $[(N_2)Mo(N(tBu)Ar)_3]^-$ and subsequent functionalization (EX = MeOTf, MeOTs, Me₃SiCl).

Reactivity of the terminal nitrido complex $[Ar(tBu)N]_3Mo\equiv N$

The terminal nitride $[Ar(tBu)N]_3Mo\equiv N$ turned out to possess weak nucleophilic character. With a variety of Lewis acids formation of adducts has been observed to give compounds of formula $[Ar(tBu)N]_3MoN-EX_3$ (X = F, E = B; X = Cl, E = B, Al, Ga, In; X = Br, E = Al; X = I, E = Al) and $[Ar(tBu)N]_3MoN-ECl_2$ (E = Ge, Sn) by simple combination of the nitride with the Lewis acid in a 1:1 ratio.^[104] These adducts show only little change in Mo-N bond length. Besides, they were observed to decompose back to the starting materials within 0.5 – 3 h in THF solution at 25°C. With strong electrophiles such as MeOTf, Me₃SiOTf or PhC(O)OTf, formation of cationic imido complexes have been observed (Scheme 17). Such imido complexes are well documented in the literature.^[105] The Mo-N-C or Mo-N-Si units are linear in the crystal structures and Mo-N bond lengths are slightly elongated compared to the parent nitride ($[Ar(tBu)N]_3Mo\equiv N$: $d(MoN) = 1.651(4) \text{ \AA}$ ^[85]; $[Ar(tBu)N]_3Mo\equiv N-SiMe_3^+$: $d(MoN) = 1.795(6) \text{ \AA}$).^[104] Methylimido complex $[Ar(tBu)N]_3Mo\equiv N-Me^+$ can be deprotonated to give a ketimide, displaying a nearly linear M-N-C unit. The N-C bond length is in agreement with the presence of a double bond ($d(NC) = 1.300(7) \text{ \AA}$), whereas the Mo-N bond distance ($d(MoN) = 1.777(4) \text{ \AA}$) lies in between a single and a double bond. This ketimide reacts with excess MeI to give the ethylimido complex $[Ar(tBu)N]_3Mo\equiv N-Et^+$, displaying the nucleophilic character of the ketimide carbon. Interestingly, the ethylimido complex could not be obtained by addition of an appropriate Et⁺ source like EtOTf, EtI or $[Et_3O]BF_4$ to the nitride. The authors state, the increased steric bulk of the electrophile presumably slows down the rate of the nucleophilic substitution reaction.^[104]

Scheme 17: Functionalization of N₂ derived terminal nitrido complex [Ar(^tBu)N]₃Mo≡N with electrophiles.

Of particular interest towards the incorporation of N₂ derived nitrogen into organic molecules is the splitting of the Mo≡N triple bond. This strong bond is needed to provide a driving force for the splitting of the N≡N triple bond, but for N₂ fixation in valuable chemicals, the Mo≡N bond needs to be cleaved again. This proved to be possible, when the nitrido complex was reacted with trifluoroacetic anhydride. Within several minutes in dimethylformamide solution, the formation of an almost quantitative amount of CF₃C(O)NH₂ has been observed.^[106] Following analysis revealed the complex is degraded upon reaction and the observed “additional” protons stem from isobutene elimination of the *tert*-butyl groups of the amide ligands. Attempts to produce isocyanates from the reaction of CO with the terminal nitrido complex failed, although DFT computations predicted a thermodynamically favorable reaction.^[107] To rationalize the difference between the molybdenum system and similar vanadium nitrides reacting with CO to isocyanates^[108,109], further DFT calculations were carried out. Based on these studies, a metal-carbonyl intermediate was proposed for the vanadium model complex, which isomerized to give the isocyanate complex, thereby avoiding a large reaction barrier.^[107]

An elegant route for nitrogen functionalization and N-atom transfer was published in 2006, wherein dinitrogen was transformed into organonitriles and the metal complex could be recovered in high yield to form a synthetic cycle (Scheme 18).^[110] Starting from Mo[N(*t*Bu)Ar]₃, N₂ is split into nitrido complexes N≡Mo[N(*t*Bu)Ar]₃, which can be functionalized with acyl chlorides RC(O)Cl (R = Ph, *t*Bu, Me) under assistance of silyl triflates. Acyl chlorides do not react with the nitride alone, the latter needs to be activated by silylation to allow for acylation. Reduction with magnesium anthracene in the presence of Me₃SiCl produces a trimethylsiloxy-substituted ketimide, which can be reacted with Lewis acids like SnCl₂ or ZnCl₂ to remove the oxygen moiety and release the respective organonitrile under generation of the chlorinated complex [Ar(*t*Bu)N]₃MoCl. Further reduction by Mg affords the starting material Mo[N(*t*Bu)Ar]₃. In this

Scheme 18: Synthetic cycle for N₂ cleavage and conversion in nitriles by a molybdenum triamido complex.

cycle, nitrile release in up to 38% over all steps proved to be possible. Each molybdenum center is oxidized by 3 electrons upon N₂ cleavage and re-reduction is a purely metal centered process. Driving force in this synthetic scheme is formation of the very strong CN triple bond ($D^0(\text{HC}\equiv\text{N}) = 937 \text{ kJ mol}^{-1}$).^[111]

In a similar approach for generation of cyanides, the nitrido complex was reacted with a mixture of MeOCH₂Cl and *i*Pr₃SiOTf.^[112] The resulting methoxymethyl-imido complex can easily be deprotonated to give [Ar(*t*Bu)N]₃MoN=CH-OMe. As described above, nitrile extrusion under oxygen removal can be carried out using SnCl₂ with concomitant generation of [Ar(*t*Bu)N]₃MoCl. However, HCN elimination proved to be difficult, as free ligand and nitride complex have been observed and no HCN could be collected via vacuum transfer. If the reaction is carried out in the presence of base (Me₃SiNMe₂, 10 eq), the major product turned out to be the molybdenum(IV) cyanido complex [Ar(*t*Bu)N]₃Mo-CN (Scheme 19). In the reaction, no external reducing agent like Mg was employed for molybdenum reduction. Instead, electrons for the formal reduction from Mo(VI) to Mo(IV) originate from the carbon, which was deprotonated during the reaction, formally delivering 2 electrons to the molybdenum center. In this way, in the overall process N≡N is transformed to Mo≡N, which is then transformed to C≡N being again the driving force for the reaction without the use of strong reducing agents.

Scheme 19: Functionalization of N₂ derived nitride into cyanide ligand.

5.2 Dinuclear side-on bridging N₂-complexes

Defined N₂-splitting into nitrides mediated by side-on bound dinitrogen has not been examined in such detail so far. The first unequivocally established cleavage in two bridging nitrides was promoted by a vanadium complex and demonstrated in 1999 by the group of *Cloke*. Reduction of a diamidoamine vanadium(III) complex {V(N[N']₂)Cl}₂ (N[N'] = (Me₃Si)N[CH₂CH₂N(SiMe₃)]₂) with one equivalent of KC₈ under N₂ atmosphere led to the isolation of neutral bis(μ -nitrido) complex

$[V(N[N']_2)]_2(\mu-N)_2$ (Scheme 20).^[113] That both nitrides originate from the same N₂ molecule was confirmed by labelling experiments employing a ¹⁴N₂/¹⁵N₂ mixture. The V₂N₂ core is planar with $d(NN) = 2.50(2)$ Å, indicating that the N≡N triple bond has been completely cleaved by concomitant oxidation of the metals to V(V, d⁰) in agreement with the diamagnetic character. Further one electron reduction (or direct 2 electron reduction from the V(III) chloro complex) is possible to form anionic V(V, d⁰)/V(IV, d¹) in agreement with magnetic measurements. Thorough experiments were carried out for understanding the electronic and vibrational structure of the reaction products.^[114]

The proposed diamidoamine V(II) intermediate displays similarities with the triamido Mo(III) system of *Cummins*. The electronic configuration is the same and the ligand environment is comparable. However, side-on coordination is assumed based on the labelling experiments. DFT calculations confirm side-on bonding of N₂ to V(II) with subsequent coordination of another V(II) to form a side-on bridged dimer, which then cleaves the N-N bond.^[115] Side-on coordination was pointed out to be preferred over end-on coordination due to the orbital disposition imposed by the diamidoamine ligand. In this way, a trans-ligand is avoided, which would raise the σ -orbitals in energy. In addition, only in a side-on coordination mode, transition of electrons in σ -antibonding orbitals can be achieved, which was stated to be a prerequisite for N₂ cleavage. Importantly, again a $\{MNNM\}^{10\pi}$ electronic configuration seems to be necessary for complete N₂ reduction.

Reactivity of the nitrido complexes has not been reported to the best of our knowledge.

Scheme 20: N₂ Splitting into bis(μ -nitrido) complex $[V(N[N']_2)]_2(\mu-N)_2$.

6 Initial N₂-splitting along the periodic table

6.1 Actinides

N₂ cleavage with f-block elements is rare, despite a variety of N₂ complexes, displaying all sorts of activation. In 2002, the group of *Gambarotta* showed N-N bond splitting by reduction of the uranium(III) complex K[(Et₈-calix[4]tetrapyrrole)U(DME)] under N₂ atmosphere.^[116] The product was identified as mixed-valent U^V/U^{IV} compound K[{K(calix[4]tetrapyrrole)U}₂(μ-NK)₂] in 61% isolated yield. Each bridging nitride also interacts with one potassium center. Reactivity of this new compound has not been reported so far.

Scheme 21: N₂-splitting promoted by uranium.

N₂ cleavage with concomitant double hydrogen atom abstract to an amine moiety has been reported for a thorium compound.^[117] Reduction of thorium(V) compound K{[O₂]₂ThCl} ([H₂O₂] = (2-hydroxy-3-*tert*-butyl-5-methyl-C₆H₂)₂CH₂) with K(naphtalene) in DME under N₂ atmosphere results in isolation of K{[O₂]₂Th(NH₂)(DME)} in up to 47% yield. Labelling experiments with ¹⁵N₂ unequivocally confirm gaseous N₂ as origin of the amide, the source of the hydrogen atoms however as well as the mechanism of formation remain unclear.

Scheme 22: N₂ cleavage into an amide group mediated by a thorium compound.

6.2 Group 4

Titanium: N₂ cleavage mediated by group 4 metals is hard to achieve, because very low valent species are needed to provide enough electrons for N₂ reduction. The group of *Gambarotta* demonstrated N₂ splitting by reduction of a well-defined titanium(III) complex LTiCl (L = 2,5-((C₄H₃N)CPh₂)₂C₄H₂N(Me)) with 1.5 equivalents of Na/Hg.^[118] The nitride-imide bridged complex [Na(dme)₃][(LTi)₂(μ-NH)(μ-N)] was isolated in 25% yield from the reaction mixture. By the use of more reducing equivalents another product [Na(dme)₃]₄[{LNa}₂][(LTi)₂(μ-N)₂] with two separate dianionic moieties was obtained. The presence of [{LNa}₂]²⁻ indicates some kind of degradation during the reaction. Treatment of the nitrido complexes with HCl resulted in ammonia formation. Whereas the complexes proved to be unreactive towards methylation, silylation using Me₃SiCl was possible yielding mononuclear LTiNSiMe₃. Dinitrogen splitting turned out to be very sensitive towards the choice of solvent, as only in DME splitting products could be observed. Identical reactions in THF only led to intractable mixtures. The mechanism for splitting is proposed to proceed via two electron reduction to a Ti(I) species with side-on coordinated N₂, which is again reduced with subsequent hydrogen atom abstraction from the solvent or ligands to form the nitrido-imido complex [(LTi)₂(μ-NH)(μ-N)]. Excess reducing equivalents is likely to reduce the N₂ complex further to the bis(μ-nitrido) [(LTi)₂(μ-N)₂]²⁻.

Another approach to achieve N₂ splitting with group 4 metals has been investigated by the group of *Hou*. Instead of using only 2 metal centers which need to deliver 3 electrons each, they used 3. Notably, reducing equivalents were not introduced by strong alkali metals, but by the use of H₂ (Scheme 23).^[119,120] Reaction of the titanium(IV) alkyl complex Cp'Ti(CH₂SiMe₃)₃ (Cp' = C₅Me₄SiMe₃) with hydrogen (4 atm) affords a mixture of the trinuclear polyhydrides (Cp'Ti)₃(μ₃-H)(μ₂-H)₆ and (Cp'Ti)₄(μ-H)₈ (not

depicted in Scheme 23) in 69% and 10% yield respectively. The latter is also the main product in similar reactions of the higher group 4 analogues Zr and Hf and stable towards N₂.^[121] The former however reacts with N₂ (1 atm) under partial H₂ elimination

Scheme 23: Ammonia synthesis out of N₂ and H₂ mediated by a polynuclear titanium hydride.

to $(\text{Cp}'\text{Ti})_3(\mu_2\text{-NH})(\mu_3\text{-N})(\mu_2\text{-H})_2$, where the N-N bond has been split under retention of the formal oxidation states of titanium (formally two Ti(III, d¹) and one Ti(IV, d⁰)). The reaction can be monitored by low temperature NMR experiments, revealing formation of a dinitrogen side-on end-on bridged complex. At -10°C, N₂ splitting takes place almost quantitatively to a bis(μ -nitrido) complex. At 20°C the latter isomerizes to the observed nitrido-imido-dihydrido complex (bottom center, Scheme 23). Further N₂ incorporation has been observed upon heating (180°C) to produce $(\text{Cp}'\text{Ti})_3(\mu_3\text{-N})(\mu_2\text{-NH})_3$. The latter as well as the nitrido-imido-dihydrido complex are stable towards hydrogenation. However, in the presence of $\text{Cp}'\text{Ti}(\text{CH}_2\text{SiMe}_3)_3$ a reaction with H₂ is observed, resulting in quantitative formation of the bis(imido) complex $(\text{Cp}'\text{Ti})_3(\mu_3\text{-NH})_2(\mu_2\text{-H})_4$. Furthermore, direct reaction of $\text{Cp}'\text{Ti}(\text{CH}_2\text{SiMe}_3)_3$ under H₂ (4 atm) and N₂ (1 atm) at 60°C also leads to generation of the bis(imido) complex in 90% yield. Addition of anhydrous HCl affords NH₄Cl together with $\text{Cp}'\text{TiCl}_3$ almost quantitatively.

In very recent work, the group of *Hou* demonstrated further N₂ incorporation of $(\text{Cp}'\text{Ti})_3(\mu_3\text{-NH})_2(\mu_2\text{-H})_4$.^[122] Heating the neat complex to 180°C under N₂ atmosphere (1 atm) affords the diimide/dinitride complex $[(\text{Cp}'\text{Ti})_4(\mu_3\text{-NH})_2(\mu_3\text{-N})_2]$ in about 95% yield (Scheme 24). Intriguingly, this complex reacts with a variety of acid chlorides to the respective nitriles in good yields (60-85%, 60°C, 12 h). Nitrogen transfer from N₂ into organic substrates is therefore accomplished in two simple steps. A μ -oxo Ti(II) complex $[(\text{Cp}'\text{TiCl}_2)_2(\mu\text{-O})]$ is characterized as reaction product besides unidentified paramagnetic Ti(III) species. Addition of ethereal HCl to the crude mixture after reaction with acid chlorides yields the trichloride $[\text{Cp}'\text{TiCl}_3]$ (83%), which is the starting material for the synthesis of $\text{Cp}'\text{Ti}(\text{CH}_2\text{SiMe}_3)_3$. In this way, a synthetic cycle is closed, in which N₂ is converted into organic nitriles via reaction with H₂ and acid chlorides with the possibility of catalyst recycling. Importantly, the system is independent of further reagents like strong reducing agents or bases. It is noteworthy, that the tetranitride analogue $[(\text{Cp}'\text{Ti})_4(\mu_3\text{-N})_4]$, obtained by dehydrogenation of the diimide/dinitride complex, does not react with acid chlorides under the same reaction conditions.

Scheme 24: Synthetic cycle for the transformation of N₂ and acid chlorides into nitriles promoted by Ti complexes.

Zirconium and Hafnium: The higher homologues of group 4 have not been observed to initially split N₂, although N₂ activation can be very strong in these complexes. Nevertheless, N₂ cleavage has been achieved by functionalization of N₂ complexes, e.g. by hydrogenation. *Chirik* and coworkers could demonstrate generation of side-on bridging N₂ complex $[(\eta^5\text{-C}_5\text{Me}_4\text{H})_2\text{Zr}]_2(\mu\text{-}\eta^2\text{:}\eta^2\text{-N}_2)$.^[78] Unlike the end-on analogue with a slightly different ligand set (see chapter 4.3), which reacts with H₂ under elimination of N₂, the side-on complex is hydrogenated to form $[(\eta^5\text{-C}_5\text{Me}_4\text{H})_2\text{ZrH}]_2(\mu\text{-}\eta^2\text{:}\eta^2\text{-N}_2\text{H}_2)$ (Scheme 25).^[77] H₂ is subsequently split over the M-N bond under nitrogen reduction to generate the diazenido unit. The dihedral angle between the Zr moieties ($\theta = 64^\circ$) turned to be crucial as calculations predict no reaction with H₂ at a dihedral angle of 0°. Only in the twisted confirmation, the HOMO is a π -symmetric orbital with NN antibonding character and a metal centered LUMO, which is well suited to accommodate a hydride ligand.^[78] Heating the hydrogenated complex to more than 45°C results in H₂ loss and N-N bond cleavage to form $[(\eta^5\text{-C}_5\text{Me}_4\text{H})_2\text{Zr}]_2(\mu\text{-NH}_2)(\mu\text{-N})$, which can be treated with HCl to afford two equivalents of NH₄Cl. Furthermore, ammonia can be generated in 10-15% yield by heating the diazenido complex to 85°C under H₂ atmosphere

Scheme 25: Ammonia formation out of N₂ and H₂ mediated by a zirconocene complex.

The similar hafnocene N₂ complex $((\text{Me}_2\text{Si}(\eta^5\text{-C}_5\text{Me}_4)(\eta^5\text{-C}_5\text{H}_3\text{-3-}^t\text{Bu})\text{Zr})_2(\mu\text{-}\eta^2\text{:}\eta^2\text{-N}_2)$ has been observed to react with CO to different products depending on the CO concentration (Scheme 26).^[123] Stoichiometric CO addition results in N-N bond cleavage, N-C bond formation and activation of one C-H bond of the ancillary ligand. NH₄Cl and HNCO can be liberated from the complex by addition of HCl. If 1 atm of CO is admitted to the dinitrogen complex, N-N bond cleavage is accompanied by C-N and C-C bond formation to a bridging oxamidate ligand $(\text{N}_2\text{C}_2\text{O}_2)^{4-}$. Protonolysis with excess HCl yields the respective mononuclear dichloride complex along with free oxamide H₂NC(O)-C(O)NH₂ in more than 90% yield.

Scheme 26: Generation of N₂ and CO derived oxamide or ammonia mediated by a hafnocene complex.

6.3 Group 5

Vanadium: The first example of vanadium mediated cleavage of N₂ was reported in 1995 by the group of *Gambarotta*. The mononuclear V(II) complex [(Me₃Si)₂N]V[CH₂(SiMe₂)N(SiMe₃)](PMe₃) was pressurized with 60 atm of H₂.^[124] Unexpectedly, a new compound was isolated in 45% yield which turned out to be a mixed-valent species with both a dinuclear vanadium cation and anion. The cation proved to be the trihydrogen bridged complex {[(Me₃P)₃V]₂(μ-H)₃}⁺ with the anion containing two bridging nitrides {[(Me₃Si)₂N]₂V₂(μ-N)₂}⁻ (Scheme 27, top). The origin of the nitrides was proposed to be N₂, as no corresponding ligand decomposition products could be detected, but was not unambiguously confirmed. One year later, *Gambarotta* and coworker demonstrated the formation of a single-nitride bridged divanadium complex presumably derived from N₂.^[125] In the reaction of TMEDA (tetramethylethylenediamine) with Li₄[(oepg)VCl₂] (oepg = octaethylporphyrinogen) a side-product formed, which was identified as [Li(tmeda)₂]{[(oepg)VLi₂]₂(μ-N)} (Scheme 27, bottom) and isolated in up to 25% yield from the reaction mixture. The nitride is coordinated square planar to four lithiums and sandwiched between two V(oepg) moieties. A magnetic moment of μ_{eff} = 2.85 μ_B was determined, which is significantly lower than expected for two V(III, d²) centers, accounting for magnetic coupling between these two metals over the nitride bridge. The source of the nitride seemed to be N₂, but could not be proven definitely by labelling experiments.

Scheme 27: N₂ splitting reactions promoted by vanadium complexes.

Gambarotta looked further into N₂ activation with low valent vanadium complexes and reported formation of a stable end-on N₂ bridged V(II)/V(II) complex.^[126] Tripyrrolide starting compound [(MeTP)V(THF)] (MeTP = 2,5-{2-[(C₆H₅)₂C]pyrrole}₂(N-Me-pyrrole)) exhibits two σ -interactions with the outer pyrrole rings and one π -interaction with the methylated pyrrole ring in the middle of the ligand (Scheme 28). The fourth coordination site is occupied by Lewis basic solvents. If the latter is extracted with a strong Lewis acid, N₂ coordinates forming the dinuclear complex [(MeTP)V]₂(μ - η^1 - η^1 -N₂). By reduction with KC_{8.8} (1 equivalent per V) N₂ cleavage is observed producing the nitride bridged species [(MeTP)V]₂(μ -N) in 52% isolated yield. Magnetic measurements are in accordance with V(III, d²)/V(IV, d¹) oxidation states. Upon addition of aqueous HCl, 43% of ammonia could be collected. In contrast to *Cloke's* vanadium system (see chapter 5.2), splitting is not achieved from V(II) but from a more reduced species. Another difference is that N₂ is coordinated end-on, whereas in *Cloke's* case DFT predict a side-on coordination.^[115] The side-on mode might be hampered for steric reasons, allowing only for end-on coordination. Therefore, a more electron rich system might be needed to achieve splitting, as orbitals in the right symmetry to allow transition in σ -orbitals must be occupied. However, the mechanism is still unclear, since the splitting reaction from the dimer to the single-nitride bridged compound is unbalanced and the nature of possible side-products is unknown.

Scheme 28: N₂ Cleavage into bridging nitride by reduction of a V(II) N₂ bridged complex and subsequent ammonia formation.

Reduction of vanadium(III) complex [(ONO)V(THF)] (ONO = 2,6-(3-*t*Bu-5-Me-2-OC₆H₂CH₂)-4-*t*Bu-(*p*-tolyl)NC₆H₄) with KH (2 equiv.) under N₂ atmosphere resulted in the isolation of paramagnetic [{K(DME)}₂{(ONO)V(μ-N)}₂] in 61% yield with concomitant formation of H₂ (Scheme 29).^[127] The N-N distance was found as 2.550(3) Å, indicative for complete N-N bond scission. The complex is stabilized by four potassium ions and magnetic measurements are in accordance with a V(IV, d¹) oxidation state for both vanadiums in the planar V₂N₂ core. Oxidation with benzoquinone generated the terminal vanadium(V) nitride [{K(DME)}{(ONO)-VN}]₂. Regeneration of the bridging nitrides by reduction with KH was not successful, suggesting that V(V) nitride is no intermediate in the N₂ splitting process. The authors propose V(I) being responsible for N₂ splitting. However, this would imply a {MNNM}^{12π} electronic configuration in contrast to what has been stated in chapter 5.1, which rather points towards V(II). Furthermore, apparently the introduced alkali metals are mandatory to stabilize the structure. Generation of H₂ during N₂ splitting might be a consequence of these additional electrons and protons introduced by KH, which have to be released in order to obtain the right electronic configuration {MNNM}^{10π}.

Nitrogen atom transfer to CO or isocyanides was accomplished, generating isocyanate and carbodiimide complexes. C-N bond formation is accompanied by reduction of V(V) back to V(III). The isocyanate ligand can be replaced by addition of alkynes. In toluene solution, potassium isocyanate precipitates under quantitative formation of [(ONO)V(η²-MeCCMe)]. Regeneration of the starting material [(ONO)V(THF)] is possible by simply dissolving the complex in THF and removing the volatiles under vacuum. Therefore, a synthetic cycle comprising N₂ splitting into nitrides, nitrogen atom transfer to CO, release of isocyanate and regeneration of the starting material is accomplished.

Scheme 29: Synthetic cycle for N₂ to isocyanate conversion promoted by vanadium complexes.

The group of *Mindiola* examined N₂ activation with vanadium(II) in analogy to *Cummins'* molybdenum(III) complex. [128] The complex (nacnac)V(ODiP) (nacnac = [(2,6-*i*Pr₂C₆H₃)NC(CH₃)₂CH; ODiP = 2,6-di-*iso*-propylphenoxide) exhibits trigonal planar geometry around vanadium and SQUID data is consistent with a V(II, d³) high spin configuration. With N₂ the end-on bridged, diamagnetic compound [(nacnac)(ODiP)V]₂(μ-η¹-η¹-N₂) is formed, displaying significant N₂ activation and two antiferromagnetically coupled V(III) centers. However, the complex turned out to be indefinitely stable at room temperature. Thermally and photochemically only liberation of N₂ was observed under regeneration of the starting material (Scheme 30). Reduction also failed to cleave the N₂ bond. To gain more insights into why the vanadium dimer does not split N₂, despite having the right geometry and electron configuration, DFT calculations have been carried out. The results show that N₂ cleavage from the dimer into terminal nitrides is thermodynamically and kinetically prohibited, due to weaker d-π* interactions in both the dimer and the nitride and a large energy barrier for structure distortions in the rigid ligand framework. To achieve a zigzag like structure and allow for transition between π and σ subspaces, structural changes are necessary, which are precluded by the chelating nacnac ligand.

Scheme 30: Reversible formation of dinuclear N₂ bridged [(nacnac)(ODiP)V]₂(μ-η¹-η¹-N₂).

Niobium: First N₂ cleavage using niobium was reported for calix[4]arene systems. The dimer M₂{[p-^tBu-calix[4]-(O)₄Nb]₂(μ-η¹-η¹-N₂)} was prepared from [{p-^tBu-calix[4]-(O)₄]₂Nb₂(μ-M)₂] (M = Li, Na, K) containing a Nb(III)=Nb(III) double bond by simple addition of N₂.^[129,130] The bridging dinitrogen is considerably activated (d(NN) = 1.390(17) Å, ν(NN) = 1372 cm⁻¹ for M = Na). Two electron reduction of the dimer using Na in THF results in N₂ cleavage and formation of bis(μ-nitrido) species [{p-^tBu-calix[4]-(O)₄]₂Nb₂(μ-N)₂(μ-Na)₂Na₂], which turned out to be in equilibrium with the terminal Nb(V) nitride Na₂{[p-^tBu-calix[4]-(O)₄]₂NbN}. The role of the solvent was revealed to be crucial as in DME (dimethoxyethane) another main-product was found, where the NN bond was retained and a Nb-Nb bond formed. In this [{p-^tBu-calix[4]-(O)₄]₂Nb₂(μ-η²-η²-N₂)(μ-Na)₃-Na] complex, dinitrogen is side-on coordinated, stabilized by additional interactions with the sodium metals and preorganized to form the bridging nitrides. Heating of the latter consistently led to the bis(μ-nitrido) compound again. Formation of the side-on coordinated compound was attributed to a metal centered reduction and stabilization of this biradical by metal-metal bond formation. Thermally induced electron transfer from the metals to nitrogen, then cleaves the NN bond. If the reaction of the Nb=Nb starting material with N₂ is carried out in toluene instead of DME or THF, no N₂ bridged complex could be isolated but the formation of trinuclear nitride bridged [{p-^tBu-calix[4]-(O)₄]₃Nb₃(μ-N)₂Na₃] is assumed, which breaks up upon addition of TMEDA into the bis(μ-nitrido) compound [{p-^tBu-calix[4]-(O)₄]₂Nb₂(μ-N)₂{μ-Na₂-(TMEDA)₂}Na₂] and the single nitride bridged species [{p-^tBu-calix[4]-(O)₄]₂Nb₂(μ-N)][Na(TMEDA)₂]. The different reaction mechanisms and products are attributed to different reaction rates in each solvent, which allows for fine tuning of the desired products.^[130]

Heterobimetallic N₂ cleavage was demonstrated by the group of *Cummins* in 2000, comprising molybdenum and niobium triamido complexes. Nucleophilic reactivity at the β-nitrogen of [(N₂)Mo(N[R]Ar)₃]⁻ has been demonstrated (see chapter 5.1).^[87] Accordingly, reaction of NbCl(N^{*i*}Pr)Ar₃ with [Na(THF)_{*x*}][(N₂)Mo(N[R]Ar)₃] afforded neutral, paramagnetic N₂ bridged complex (Ar[^{*t*}Bu]N)₃Mo(μ-N₂)Nb(N^{*i*}Pr)Ar₃ (Scheme 31).^[131] One electron reduction yielded the known molybdenum(VI) nitride (Ar[^{*t*}Bu]N)₃MoN and the isoelectronic terminal nitride [K(cryptand-222)][(N)Nb(N^{*i*}Pr)Ar₃]. Oxidation of the latter produced a niobazene cyclic trimer {(μ-N)Nb(N^{*i*}Pr)Ar₂]₃ in up to 41% yield. Interestingly, the trimer exhibits 2 different Nb-N bond length, one short (average d(NbN) = 1.791(7) Å) and one long (average d(NbN) = 2.004(6) Å), which are attributed to π-interactions with the amide lone pairs of the ancillary ligands. Importantly, *Cummins* and coworkers developed a synthetic cycle for N₂ to nitrile conversion, similar to the homometallic molybdenum system, published shortly after.^[110,132] Addition of [(N₂)Mo(N[R]Ar)₃]⁻ to the niobium(IV) compound Nb(OTf)(N[Np]Ar)₃ (Np = neopentyl) affords the heterodinuclear complex (Ar[Np]N)₃Nb(μ-N₂)Mo(N^{*t*}Bu)Ar₃, which splits N₂ upon 1 electron reduction to the respective terminal nitrides. In a methathetical N for OCl

exchange, addition of acyl chlorides RC(O)Cl generates nitriles RCN, NaCl and the niobium(V)-oxo complex Nb(O)(N[Np]Ar)₃. By addition of trifluoromethanesulfonic anhydride (Tf₂O), the oxo-group is converted into triflate (OTf), generating Nb(OTf)₂(N[Np]Ar)₃. The latter can be reduced with Cp₂Co to the starting compound Nb(OTf)(N[Np]Ar)₃.^[132] By ligand modification an acylimido complex could be trapped, which converts into the oxo-complex upon heating. Therefore acylimido complexes are implicated as intermediates in nitrile generation. A variety of nitriles can be synthesized in high yield, providing the opportunity of selective, atom-efficient ¹⁵N-labelling employing ¹⁵N₂.

Scheme 31: Synthetic cycle for N₂ to organonitrile conversion mediated by a heterobimetallic Nb/Mo system.

The niobium(III) compound [P₂N₂]NbCl (P₂N₂ = PhP(CH₂SiMe₂NSiMe₂CH₂)₂PPh) can be reduced under N₂ atmosphere to afford paramagnetic dinuclear { [P₂N₂]Nb }₂(μ-η¹-η¹-N₂) (Scheme 32).^[133] Magnetic measurements reveal the existence of two antiferromagnetically coupled Nb(IV, d¹) centers and therefore a [N₂]⁴⁻ bridge. Consistently, protonation of the dimer with HNMe₃Cl yields hydrazine in 62% yield. Heating of the dimer at 110°C for 12 h results in formation of a new paramagnetic compound, which was identified as single nitride bridged dinuclear complex. The second nitrogen of the N₂ unit was observed to insert into the ligand backbone giving [PN₃]Nb-(μ-N)-Nb[P₂N₂] ([PN₃] = PhPMe(CHSiMe₂NSiMe₂CH₂P(Ph)-CH₂SiMe₂NSiMe₂N)). Magnetic examinations as well as crystallographic data support disproportionation of the two Nb centers into a Nb(III, d²)/Nb(V, d⁰) couple with S = 1.

Scheme 32: N₂ cleavage into a bridging nitride under insertion of one nitrogen in the M-P bond.

The mechanism of the splitting reaction is proposed to proceed via initial nitride formation. Phosphine attack at the nitride allows for P-N bond formation. Subsequent insertion of the nitride into the C-Si bond results in N-Si bond formation and transfer of the methylene group to the phosphorous. The resulting phosphamethylene is then protonated from an adjacent CH₂ group. However, the {MNNM}^{8π}, 2^δ unit is not in agreement with the electronic configuration for NN splitting stated in chapter 5. The complex may be destabilized by the two strong π-donors in the ligand backbone, opening the possibility of induced NN splitting by phosphine attack at one nitrogen. Following DFT studies compared *Fryzuk's* Nb system with *Cummins' Mo* system.^[134] In contrast to the latter, N₂ cleavage was calculated to be largely endothermic from the Nb-N₂-Nb dimer to terminal nitrides, whereas formation of the single bridging nitride was found exothermic. The ligand constraints in the [P₂N₂] were observed to have a dramatic effect on the overall reaction enthalpy, but especially on the N₂ cleavage step. Allowing the ligands to relax, revealed rotation of the amides about 90°C in a way that they lie in plane with the Nb-N bond. In this way the product nitride was found significantly lower in energy. Additionally, the exchange of the PR₃ groups by NR₃ groups were found to similarly increase the exothermicity of the reaction, as the resulting nitride would be considerably more stabilized with more electronegative and stronger bonding amine ligands.

In 2002, the group of *Kawaguchi* demonstrated N₂ cleavage by reduction of a Nb(V) dimer.^[135] The complex [Nb(^tBu-L)Cl₂]₂ with tridentate aryloxy ligands was reduced with 6 equivalent LiHBET₃ and formation of the bis(μ-nitrido) complex [Nb(^tBu-L)(μ-N)Li(thf)]₂ was observed in 41% yield. As reduction under argon afforded a bridging hydride complex, dinitrogen splitting was considered to proceed via such an intermediate under H₂ elimination. This assumption was supported when in 2007 a (μ-H)₄ complex was isolated.^[136] HNet₃([O₃]NbCl₃) (H₃[O₃] = tris(3,5-di-tert-butyl-2-hydroxyphenyl)methane) can be reduced with 4 equivalents of LiHBET₃ to generate K₂{([O₃]Nb)₂(μ-H)₄} under reduction of Nb(V, d⁰) to Nb(IV, d¹). The small Nb-Nb distance in the crystal structure indicates a metal-metal bond, accounting for the observed diamagnetism of this species. Interestingly, although rather high valent, the complex reacts with N₂ under H₂ elimination and N-N bond cleavage to the bis(μ-nitrido) complex K₂{([O₃]Nb)₂(μ-N)₂} (Scheme 33). Four of the six electrons needed

for N₂ splitting have been stored in the hydride ligands and two in the metal-metal bond, allowing for splitting without further reagents. Addition of 2,6-lutidinium chloride results in formation of ammonia in 61% yield under formation of the chloride complex $[\text{O}_3]\text{NbCl}_3$.^[137] The latter can be recycled to hydrido complex $\text{K}_2\{([\text{O}_3]\text{Nb})_2(\mu\text{-H})_4\}$ with KBHET_3 , thus generating a synthetic cycle for conversion of N₂ into NH₃.

Scheme 33: Synthetic cycle for N₂ derived ammonia formation mediated by a Nb triaryloxide complex.

C-N bond formation was demonstrated by addition of methyl iodide (MeI) (Scheme 34). Whereas one bridging nitride is readily methylated, methylation of the second needs prolonged heating yielding neutral $[\text{O}_3]\text{Nb}_2(\mu\text{-NMe})_2$ after 5d at 60°C.^[136] Cleavage into monomers is accomplished by addition of a Lewis base: Addition of pyridine (py) generates the mononuclear imido complex $[\text{O}_3]\text{Nb}(\text{NMe})(\text{py})_2$.^[137] Whereas the bridging nitride species does not react with CO₂, presumably because of low nucleophilicity and large steric bulk, a reaction of the mononuclear imido complex and CO₂ is observed generating a mixture of ureate complex $[\text{O}_3]\text{Nb}[(\text{NMe})_2\text{CO}](\text{py})$ and dinuclear bis(μ-oxo) $\{[\text{O}_3]\text{Nb}\}_2(\mu\text{-O})_2$ in a 2:1 ratio. The reaction is proposed to proceed via initial [2+2] addition of CO₂ with subsequent extrusion of isocyanate MeNCO and formation of an oxo complex, which then dimerizes. Isocyanate is reacting with another imido complex to form the observed ureate complex. However, no intermediates or free MeNCO could be detected. Liberation of the carbodiimide out of the product has not been shown yet.

6. Initial N₂-splitting along the periodic table

Scheme 34: Functionalization of N₂ derived bis(μ -nitrido) Nb complex with MeI.

The group of Mindiola recently demonstrated N₂ splitting starting from Nb(IV) and Nb(V) aryloxy complexes under reducing conditions.^[138] 4 electron reduction of dinuclear complex [(ArO)₂Nb(μ -Cl)Cl₂]₂ (ArO = 2,6-bis(diphenylmethyl)-4-*tert*-butylphenoxide) yields the Nb(III) compound K₃[(ArO)₄Nb₂(μ -Cl)₃Cl₂], which is stable towards dinitrogen (Scheme 35). Two electron reduction yields Nb(IV) complex [trans-(ArO)₂NbCl₂(THF)₂]. Four electron reduction of the dinuclear starting material readily affords the bis(μ -nitrido) complex [(ArO)₂Nb]₂(μ -N)₂ at room temperature. Further reduction is possible yielding anionic K[(ArO)₂Nb]₂(μ -N)₂, which can in turn again be oxidized to the neutral form. Addition of anhydrous HCl (ex.) to both nitrido complexes led to formation of NH₄Cl. However, a synthetic cycle was not possible, as also the aryloxy ligands are protonated and dissociate. Since the chloride bridged Nb(III) complex does not react with N₂, the authors conclude that bridging chlorides or metal-metal bonds prevent reactions with N₂.

Scheme 35: Reduction of a Nb(V) dimer with different reducing equivalents.

Tantalum: Storage of reducing equivalents for N₂ in the form of hydrides has been well examined with tantalum complexes. *Fryzuk* and coworkers demonstrated that dinuclear Ta(IV) hydride complex {[NPN]Ta}₂(μ-H)₄ ([NPN] = PhP(CH₂SiMe₂NPh)₂) reacts with N₂ to partially release H₂ and to produce dinitrogen compound {[NPN]Ta}(μ-H)₂(μ-η²-η¹-N₂) with N₂ being bound side-on end-on.^[81] Subsequent treatment with boranes^[139], silanes^[140-142], aluminum or zirconium hydrides^[143,144] or with 1,2-cumulenes^[145] led to cleavage of the dinitrogen bond.

A surface organometallic approach for N₂ functionalization is examined in the group of *Quadrelli*. Ta(III) and Ta(V) hydrides are grafted on a silica surface and exhibit thermal robustness without dimerization or sintering, preserving the molecular site isolation and environment of homogenous complexes. These silica supported complexes [(≡SiO)₂TaH_x] (x = 1, 3) not only activate ammonia or hydrazine, but also N₂.^[146-148] The reaction with N₂ produces imido-amido-tantalum(V) [(≡SiO)₂Ta(=NH)(NH₂)] at 250°C under atmospheric pressure of H₂.^[146] DFT calculations reveal that tantalum always stays in its high oxidation state and dinitrogen is reduced by hydride transfers or reduction with H₂, which is the source of protons and electrons.^[149]

The group of *Sita* examined all group 5 metals in the Cp*am ligand framework towards reactions with N₂.^[63] They discovered, that reduction of the vanadium(III) precursor Cp*amVCl under N₂ leads to thermally robust dinuclear [Cp*amV](μ-η¹-η¹-N₂). Similar to *Mindiola's* experiments (see above) N₂ cleavage did not seem to be possible and only replacement of N₂ with isonitriles was observed. End-on N₂ bridged complexes with niobium^[63] and tantalum^[61] were also synthesized and these display significantly stronger N₂ activation (see Table 1). The stability of the dimers strongly depends on the substituents of the amidinate ligand with bigger substituents like phenyl, producing the most stable complexes. Small ligand substituents like methyl and/or temperatures above 0°C afford the respective bis(μ-nitrido) complexes, thus thermal cleavage of the N-N bond (Scheme 36). The niobium N₂ complexes turned out to be the least stable, cleaving directly into the dinuclear nitride species with methyl substituted amidinate. Kinetic measurements suggest that the energy barrier for N₂ cleavage with niobium is significantly smaller as for the tantalum analogue and sterically demanding substituents stabilize the N₂ complex kinetically. The mechanism is likely to proceed via side-on coordinated N₂ as it has been proposed for *Floriani's*^[130] and *Fryzuk's*^[133] niobium complexes and by theoretical investigations.^[94,150] As intermediate mononuclear nitrides could not be ruled out, additional experiments were performed by isotopic labelling.^[63] Kinetic isotope effects as well as crossover experiments support side-on configuration. In addition, treatment of the tantalum end-on bridged N₂ complex with N₂O generated side-on bound N₂ and a bridging oxo [Cp*amTa]₂(μ-η²-η²-N₂)(μ-O), confirming that this coordination mode is possible with Ta(V). Functionalization of the tantalum nitride could be achieved in terms of N-Si bond formation with silanes.^[61] No reaction of the

nitride with H₂ could be observed and DFT calculations show a large energy barrier as well as high endothermicity for this hydrogenation.^[150]

Scheme 36: Reduction of Nb or Ta complexes to produce end-on bridging N₂ dinuclear dimers which thermally cleave the N-N bond and functionalization of the resulting nitrides with silanes.

6.4 Group 6

Thermal N₂ cleavage promoted by molybdenum

Molybdenum complexes are very well studied in N₂ activation chemistry, not only because Mo has been found in the cofactor of the nitrogenase, but also because of the aforementioned first defined N₂ splitting of *Cummins*. In 2012, the group of *Schrock* achieved full N₂ cleavage in terminal nitrides by employing a Mo(III) complex with POCOP pincer ligand (POCOP = 2,6-[OP(^tBu)₂]₂C₆H₃).^[151] Reduction of (POCOP)MoI₂ with Na/Hg and 15-crown-5 under N₂ atmosphere produces [Na(15-crown-5)][(POCOP)Mo(N)(I)] (Scheme 37). The Mo≡N bond length is comparable with *Cummins* Mo(VI) nitrido complex (d(MoN) = 1.659(2) Å and d(MoN) = 1.651(4) Å respectively). *Schrock's* nitride however is in accordance with a Mo(IV) low spin formulation. The splitting mechanism has not been examined in detail, but it has been proposed to proceed via a (μ-η¹:η¹-N₂) bridged dimer analogous to *Cummins* system, which then splits into a Mo(V) nitride which is subsequently reduced to the observed anionic Mo(IV) nitride. Alternatively, presumably formed Mo(II)-N₂-Mo(II) dimer is first reduced by two electrons and cleaves thereupon. The last assumption would be supported by molecular orbital considerations in analogy to *Cummins* system. In both cases the starting compounds are isoelectronic Mo(III) complexes, but in *Schrock's* system, the complex is in a fourfold geometry. In a MO scheme of the dimer, this results in two additional δ-orbitals. To reach the same {MNNM}^{10π} electron configuration as in *Cummins* dimer, there is need for 4 additional electrons (2 per molybdenum) consistent with experimental data. Another driving force for the N-N bond cleavage would then be the electronic repulsion between the two negatively charged molybdenum units.

Protonation of the nitrido complex with [Et₃NH][BAr^F₄] leads to formation of a neutral species, in which the proton bridges between the Mo and one P atom. Since

the nitride could not be protonated, catalytic ammonia formation seemed unpromising. So it was not surprising, that under *Nishibayahshi's* conditions [36] only 0.34 equivalents and under *Schrock's* catalysis conditions [31] 0.30 equivalents of ammonia were detected.

Scheme 37: N₂ Cleavage and subsequent protonation of the formed terminal nitride with Schrock's {(POCOP)Mo} system.

Recently, the group of *Mézailles* reported N₂ splitting by 2 electron reduction of a Mo(III) complex with PPP pincer ligand (P^{Ph}P₂^{Cy})MoCl₃ in the presence of NaI under N₂ atmosphere.^[152] An analogous mechanism to *Schrock's* system has been proposed and the terminal nitride [(P^{Ph}P₂^{Cy})Mo(N)(I)] was observed in 80% spectroscopic and 60% isolated yield (Scheme 38). An intermediate Mo(I) dimer is in agreement with a {MNNM}^{10π4δ} electronic configuration as it may be involved in *Schrock's* example. The respective η¹-η¹-N₂-bridged Mo(0) ({MNNM}^{12π4δ}) compound with additional end-on coordinated N₂ [(P^{Ph}P₂^{Cy})Mo(N₂)₂(μ-N₂)Mo(N₂)₂(P^{Ph}P₂^{Cy})] was reported earlier and did not result in N₂ splitting into nitrides.^[153]

Scheme 38: 2 electron reduction of (PPP)MoCl₃ yielding the terminal nitride (PPP)Mo(N)(I).

The terminal nitride could be functionalized by addition of silanes under N-Si bond formation. Importantly, the use of bis(silanes) enables a second intramolecular Si-H insertion and generates free bis(silyl)amine and a molybdenum(II) hydride (Scheme 39). The latter could not be characterized yet, however reduction to Mo(II) could be verified by addition of PMe₃ and resulted in the isolation of [(P^{Ph}P₂^{Cy})Mo(H)(I)(PMe₃)]. Regeneration of the Mo(I) species to close a synthetic or even catalytic cycle could not be accomplished so far, but represents an intriguing approach. Removal of one H-atom would generate the Mo(I) species required for N₂ splitting without the need of strong reducing agents.

Scheme 39: Functionalization of a N₂ derived terminal nitride with bis(silanes).

N₂ cleavage by photolysis promoted by molybdenum and tungsten

First photoinduced N₂ splitting was demonstrated by the group of *Floriani* in 2001. Exposure of thermally stable [(Mes)₃Mo]₂(μ-η¹-η¹-N₂) to UV light (λ = 365.0 nm) produces the single nitrogen bridged compound [(Mes)₃Mo]₂(μ-N). *Floriani* proposes a mechanism that consists of initial light induced N₂ splitting into monomeric nitrides, which then act as a Lewis base and react with excess starting material to form a transient tetranuclear [Mo-N-Mo-N-N-Mo-N-Mo] species. This compound loses N₂ and forms the observed bridging nitride (Scheme 40). In agreement with a {MNM}^{7π} system leading to a doublet spin state, the isolated compound is paramagnetic with μ_{eff} = 1.68 μ_B. The linear M-N-M core (179.1(3)°) displays M-N bond distances (d(MoN) = 1.952(5) and 1.936(5) Å) which are significantly longer than in similar [L₃Mo]₂(μ-N) compounds.^[90,92,93] An alternative mechanism is proposed by *Cummins*, who could demonstrate N-N and M-N cleavage being in competition. Coupling of intermediate terminal nitride with (Mes)₃Mo would also generate the observed nitrogen bridged species.^[85]

Scheme 40: N₂ cleavage by photolysis of N₂ bridged dimer [(Mes)₃Mo]₂(μ-η¹-η¹-N₂) as proposed by Floriani.

In 2014, the groups of *Nishibayashi* and *Yoshizawa* published an end-on N₂ bridged dimer supported by a ferrocenyldiphosphine ligand, which cleaves N₂ under visible light irradiation at room temperature into the corresponding terminal nitrides. Moreover, the nitrides can be oxidized to reform the N-N bond and to produce an N₂ bridged dimer again.^[154,155] The dinuclear monocationic complex [{Mo(depf)(Cp*)}₂(μ-η¹-η¹-N₂)] [BAR^F₄] (depf = 1,1'-bis(diethylphosphino)ferrocene) can either be oxidized to the dicationic compound or reduced to the neutral dimer (Scheme 41). As in the case of *Cummins* isolated N₂ bridged dimers (Figure 12), the

neutral complex exhibits the lowest N₂ activation and longest Mo-N bond distances ($d(\text{MoN}) = 1.955(4) \text{ \AA}$). With increasing positive charge, N₂ activation becomes larger ($d(\text{NN}) = 1.226(4) \text{ \AA}$ for the cation, not depicted in Scheme 41). However, only the neutral complex contains a $\{\text{MNNM}\}^{10\pi}$ system stated necessary for splitting. Consistently, only the neutral complex cleaves the N-N bond, not thermally though, but upon photochemical excitation ($580 \text{ nm} > \lambda > 400 \text{ nm}$) to form the corresponding Mo(IV) terminal nitrides. Simulated UV/Vis spectra and electron density difference maps point out loss of electron density for a transition around 500 nm, which could therefore be responsible for the cleavage of the bridging N₂. Oxidation of the nitride leads to dimerization to the dicationic N₂-bridged complex $[\{\text{Mo}(\text{depf})(\text{Cp}^*)\}_2(\mu\text{-}\eta^1\text{-}\eta^1\text{-N}_2)][\text{BAR}^{\text{F}_4}]_2$ (**A**). Coupling of nitrides is usually observed for late transition metals. For rhodium and iridium nitrides a nitridyl radical $\text{M}=\text{N}\cdot$ is proposed as key reactive intermediate with spin density being almost equally distributed over the M-N unit.^[156,157] In contrast, nearly no spin density on the nitrogen could be found by DFT calculations for the molybdenum system. If oxidation is carried out in the presence of cyclohexadiene though, a mixture of the dicationic dimer and the cationic Mo(IV) imide results (**B**), demonstrating hydrogen atom abstraction still being possible. In the presence of a proton source, the same products are observed with concomitant generation of H₂. Besides, 0.37 equivalents of ammonia could be detected by reaction with excess CoCp_2^* and $[\text{LutH}][\text{BAR}^{\text{F}_4}]$ under argon.

Scheme 41: N₂ cleavage and functionalization mediated by a $\{\text{Mo}(\text{depf})(\text{Cp}^*)\}$ complex.

Sita and coworkers demonstrated formation of end-on coordinated N₂ bridged dinuclear molybdenum and tungsten complexes bearing Cp* and amidinate ligands.^[62] These complexes exhibit a {MNNM}^{8π, 4δ} unit and proved to be thermally stable. Exposure to irradiation however, results in splitting of the N-N bond.^[158] In the case of molybdenum two products were identified, a bis(μ-nitrido) complex [Cp*amMo]₂(μ-N)₂ with formal Mo(V, d¹), Mo(V, d¹) centers and a single nitrogen bridged species [Cp*amMo]₂(μ-N) with formal Mo(III, d³), Mo(IV, d²) centers (Scheme 42).

Scheme 42: N₂ cleavage in μ-nitrido and complexes and bis(μ-nitrido) complexes and functionalization of the latter with electrophiles.

These findings are consistent with the reported observation of both N₂ cleavage and N₂ extrusion upon photolysis of N₂-bridged dinuclear complexes as described earlier (see chapter 5.1).^[85,99] For the corresponding tungsten analogues, only the bis(μ-nitrido) complex were found. These react with R₃ECl (R₃E = Me₃Si, Ph₃Si, Me₃Ge, Me₃C) to produce a 1:1 mixture of the mononuclear nitride-chloride complex Cp*amM(N)(Cl) and the functionalized imido complexes Cp*amM(N-ER₃). The mechanism is thought to proceed via chloride-atom abstraction and capture of the so formed ECl₃ radical to give two mononuclear species. Interestingly, combination of the photochemical N₂ cleavage with the functionalization in a one pot reaction yielded solely the imido complex and the dichloride Cp*amMCl₂ in a 2:1 ratio. Since reaction of the imido complexes with CO to liberate isocyanates under formation of a bis-CO complex had been shown before, N₂ derived nitrogen group transfer is possible with isocyanate yields up to 64%.^[158,159] The bis-carbonyl complexes is converted to the respective dichlorides by reaction with CO₂ and Me₃SiCl. The dichloride complexes can be reduced under N₂ atmosphere with sodium to yield the N₂-bridged dinuclear compounds again.^[62] In this way, a synthetic cycle can be closed for transformation of N₂ into isocyanates. To simplify this multistep cycle, *Sita* and coworkers worked out a more efficient path (Scheme 43). Reaction of the imido complexes with CO₂ (1.4 - 4.8 bar) and excess Me₃SiCl produces directly the dichloride together with free isocyanate. Here, simultaneous nitrogen group and oxygen atom transfer takes place. The whole N₂ fixation reaction in one pot yielded up to 82% of recovered starting

material after one cycle, providing a highly efficient platform and an excellent starting point for catalytic N₂ functionalization.

Scheme 43: Synthetic cycle for N₂ to isocyanate conversion by Sita.

Chromium: An evaluation of the group of *Schrock* in 2006 pointed out, that N₂ activation with chromium is more difficult compared to molybdenum especially attributed to the low lying high spin states and the weak reduction potential of Cr(III) compounds.^[160] In addition, DFT calculation in the group of *Stranger* predict N₂-splitting with Cr(III) in a triamido ligand system to be unlikely due to thermodynamic reasons.^[97] In 2007 however, the first example of N₂ cleavage mediated by a well-defined chromium complex was reported by the groups of *Budzelaar* and *Gambarotta*.^[161] Reduction of N₂ bridged dichromium complexes with diiminepyridine ligands $\{[2,6-[2,6-(iPr)_2PhN=C(CH_3)]_2(C_5H_3N)]Cr(THF)\}_2(\mu-\eta^1-\eta^1-N_2)$ with 2 equivalents of NaH lead to a species with a bridging NNH unit. The N-N bond was elongated but still intact and the hydrogen stemmed from one of the methyl groups in the diimine ligand transferred in a formal hydrogen atom abstraction from carbon to the N₂ unit. Treatment with an additional equivalent of NaH, splits the N-N bond and forms an anionic chromium imide. Ammonia could be collected in 87% yield after addition of aqueous HCl and further workup. Another example of ammonia formation mediated by chromium N₂ complexes was reported by the group of *Mock* upon addition of several equivalents of acid to a formal chromium(0) bis(η^1-N_2) complex.^[162] However, ammonia was only a side-product with the main product being hydrazine.

6.5 Group 7

For transition metals of group 7, no initial N₂ cleavage has been observed until the start of this PhD thesis in 2013, although nitrides are well-known.^[105] For manganese,

dinitrogen coordination and even its functionalization into azomethane has been reported, however the N-N bond has not been cleaved.^[163]

6.6 Group 8

Iron: Iron is together with molybdenum the most studied metal for dinitrogen activation, as both are present in the active site of the nitrogenase and iron surfaces are used as catalysts in the *Haber Bosch* process. Accordingly, there have been published many dinitrogen complexes of iron and formation of ammonia with such complexes is not unknown, however these complexes and/or their mechanisms are often rather ill-defined and yields are low.^[46,164–167] Iron nitrides are also known and exhibit interesting reactivity. Ammonia formation by hydrogen atom transfer has been reported and even electrophilic character of iron nitrides by reactions with CO or isonitriles has been shown, pointing towards an intriguing path towards nitrogen functionalization into organic compounds.^[168,169] Nevertheless, iron dinitrogen complexes have not been reported to cleave into defined nitrides until 2011. *Holland* and coworkers reported a multinuclear iron potassium complex with N₂-derived bridging nitride units.^[170] The authors started their investigations using bulky, low coordinate iron(II) chloro complexes as starting materials, which are depending on their steric demand either mono- or dinuclear. Two electron reduction of the mononuclear β -diketiminato complex LFeCl (L = HC[C(^tBu)N(2,6-ⁱPr₂C₆H₃)]₂) yields dinuclear N₂ bridged K₂[LFeNNFeL], where dinitrogen is end-on bridging two iron centers and side-on to two potassium ions.^[171] N₂ is relatively strongly activated for a formally iron(0) compound (d(NN) = 1.23 Å, ν (NN) = 1589 cm⁻¹).^[164,166] Decreasing the steric bulk by using a methyl substituted diketiminato ligand led to the isolation of a compound containing 2 potassium, 4 iron, 2 chloride atoms together with two bridging nitrides (Scheme 44).^[170] The N-N distance of 2.799(2) Å accounts for complete scission of the bond. The rather complicated structure involves one nitride bridging three iron centers and the other nitride bridging two irons and to potassiums. Each potassium interacts with two chlorides, which are connected to the fourth iron. NMR studies suggest that the structure is also held in solution. Mössbauer spectra reveal the existence of two high-spin Fe(II) and two high-spin Fe(III) centers, which is in agreement with a 6 electron reduction of N₂ by four formal Fe(I) formed by reduction of the Fe(II) precursor. The participation of four iron centers for N₂ reduction avoids the formation of high oxidation states and five Fe-N bonds provide a driving force for the reaction. Theoretical investigations indicate that initial formation of a FeNNFe core is followed by coordination of a third Fe(I) complex in a side-on mode, which is only possible if the steric demand of the ligands allows such a conformation. After rearrangement to a side-on / side-on / end-on conformation, the fourth iron coordinates and enables N-N cleavage. These investigations also point out

the importance of an alkali metal for stabilization of the resulting nitride.^[172] Following research revealed that apparently the right number and size of the alkali metals influences the N-N splitting reaction. Too many alkali metals introduced by over-reduction or too big alkali metals like caesium have been found to inhibit N-N cleavage, presumably because they cannot hold the right geometry of the Fe₃(N₂) unit necessary for splitting.^[173] Addition of 100 equivalents of anhydrous HCl gave ammonia in 82 ± 4 % yield, demonstrating the nucleophilic reactivity of the nitrides. Unfortunately, the complex degrades under these conditions what imposes difficulties to a catalytic application.^[167,170] The bis(μ-N) complex is reported to degrade slowly in benzene solution at room temperature with the main decomposition product being a LFe(benzene) complex.^[174] Therefore, coupling of the nitrides back to N₂ was assumed. Addition of strong π-acceptor ligands like isonitriles or CO supports this assumption as they stabilize the resulting Fe(I) species LFe(L')₃ (L' = CO, CNAr) under release of N₂. These results demonstrate that the system can both cleave and form the N-N bond without thermodynamic sinks which are often a problem in nitride chemistry.

Scheme 44: N₂ cleavage and ammonia formation mediated by a dinuclear iron compound.

Murray and coworkers used the multimetal cooperative approach to design a triiron(II) complex, which is reported to cleave dinitrogen after reduction with K₈C₈ under N₂ atmosphere.^[175] The three iron centers in the main product were found to bridge through three NH_x functions. Mössbauer spectra show the presence of mixed-valent triiron (II/II/III) centers in the resulting complexes. Since there are three nitrogen atoms per cluster, intra- and inter-complex cooperativity is assumed for the N₂ splitting process. The origin of the hydrogens in the bridging NH_x moieties could not be determined so far. Reaction in silylated glassware, deuterium labelling experiments and addition of compounds with weak C-H bonds (9,10-dihydroanthracene) did not give any satisfactory results. Upon addition of HCl about 30% of ammonia could be detected, indicating that only one of three nitrogen units can be liberated in this way.

Ruthenium: Despite many ruthenium N₂ complexes, cleavage of the N≡N bond has not been observed so far. Ruthenium nitrides on the other hand are well-known and even reported to react with H₂ to form ammonia.^[176] Nevertheless, ruthenium dinitrogen complexes show only minor N₂ activation and N-N bond splitting in defined complexes has only been reported for the reaction of ruthenium hydride complexes with hydrazine.^[177,178] DFT calculations however, suggest ruthenium pincer complexes to be the most promising of the group 8 metals concerning NH₃ formation from N₂ and H₂.^[179]

Osmium: Osmium dinitrogen complexes have not been shown to cleave N₂ in the electronic ground state so far. *Vogler* and coworkers demonstrated however N₂ cleavage from the mixed valent Os(II)/Os(III) complex $\{[(\text{NH}_3)_5\text{Os}](\mu\text{-}\eta^1\text{-}\eta^1\text{-N}_2)\}^{5+}$ by irradiation in aqueous solution.^[180] Formation of the osmium(VI) nitride $[\text{Os}^{\text{VI}}(\text{NH}_3)_4\text{N}]^{3+}$ was stated by comparison of UV/Vis and excitation spectra. Another product was identified as $[\text{Os}^{\text{III}}(\text{NH}_3)_4(\text{H}_2\text{O})]^{3+}$. Disproportionation of the unstable osmium(V) nitride $[\text{Os}^{\text{V}}(\text{NH}_3)_4\text{N}]^{2+}$ as intermediate after N₂ cleavage is assumed. Consistently, in the presence of oxygen as oxidant the yield in Os(VI) nitride product was enhanced. Striking is the presumed protonation of intermediate $[\text{Os}^{\text{IV}}(\text{NH}_3)_4\text{N}]^+$ to release ammonia and form the observed aqua-complex. The presence of Os^{II} turned out to be crucial as by irradiation of the Os(II)/Os(III) dinitrogen bridged complex in a qualitative experiment only vigorous evolution of N₂ was observed. The higher energy of metal to ligand charge transfer (MLCT) for Os^{III} compounds was attributed to this observation. Irradiation of the mixed-valent species in the presence of OCl₂ yielded a new species, which was identified as $[\text{Os}(\text{NH}_3)_5\text{NO}]^{3+}$ and represents unusual oxidative N₂ cleavage.^[181]

7 Scope of this work

Several examples for transition metal (TM) mediated initial N_2 splitting were described in the previous chapter. However, defined systems for full 6 electron reduction of N_2 into nitrides still remain scarce. The formation of strong M-N bonds in order to overcome the large N_2 dissociation energy is a prerequisite, accordingly examples are reported commonly for early transition metals until group 6. As the bond dissociation energies (BDEs) for diatomic $[M\equiv N]^+$ decrease along the TM series ($M = \text{Ti-Cu}$), N_2 cleavage into nitrides is favored with these systems.^[182] However, the main disadvantage of these formed terminal nitrides is their stability and inertness towards N-centered functionalizations due to the aforementioned strong $M\equiv N$ bonds. Even if such functionalizations are achieved, the availability of empty d-orbitals caused by high oxidation states strengthens the resulting M-NR_x bond and liberation of the functionalized nitrogen containing moiety is subject to significant kinetic and thermodynamic barriers.^[14]

By going to the right in the periodic table, more electron rich complexes are generated and population of M-N π^* orbitals disfavors multiple bonded nitrogen. Low valent late transition metal terminal nitrides are challenging to synthesize and only few examples for such complexes are reported, employing iron,^[183-187] ruthenium,^[176,188] osmium,^[189] rhodium^[157,190] and iridium,^[156,191] albeit not from N_2 .^[14]

Aim of this thesis is combining strong $M\equiv N$ BDE and thus enabling N_2 cleavage with mid to late transition metal nitride reactivity observed for electron rich complexes. Rhenium as group 7 element accounts for the metal of choice. N_2 splitting into nitrides, their functionalization and finally the liberation of nitrogen-containing compounds on the same metal platform represents the central goal.

As described in chapter 5, prerequisite for N_2 cleavage is an $\{MNNM\}^{10\pi}$ entity, which affords a low valent rhenium species as stable precursor for N_2 activation. Furthermore, the complex must allow for N_2 coordination, i.e. by offering a vacant coordination site. Flexible platforms for stabilizing various oxidation states have been successfully demonstrated by the *Schneider* group with the PNP pincer ligand of two phosphine and one amide donor bridged by an ethylene backbone prone to further amide donor fine tuning by ligand oxidation. By variations of the ligand such as reduction of steric bulk on phosphorous or decreasing the amides π -donor strength upon backbone oxidation, the splitting process can be examined in more detail to get more insights about the requirements and steric and electronic influences.

With the nitride in hand, functionalization experiments and reactivity studies will be executed. Rhenium nitrides usually react nucleophilic,^[105] however electrophilic reactivity cannot be excluded. The aim of all functionalization reactions is to extrude the nitrogen containing moiety in order to convert N₂ into chemically more valuable compounds. Standard experiments comprise protolysis or hydrogenation reactions to liberate ammonia. As described in chapter 1, about one-fifth of all NH₃ produced in the *Haber-Bosch* process is used for organic molecules.^[11,12] In this regard, N₂ is reduced to NH₃ in a tremendously energy extensive process, which then needs to be reacted in a second step with organic compounds, like alkenes. Therefore, using N₂ directly as NH₃ surrogate under ambient conditions is an appealing goal. Especially organic nitriles represent an attractive synthetic target, as the conversion of N₂ to RCN conserves the high energy triple bond. Therefore, the high energy demand for the cleavage of the strong N≡N bond (941 kJmol⁻¹) can be offset by the formation of strong C≡N bonds ($D^0(\text{HC}\equiv\text{N}) = 937 \text{ kJmol}^{-1}$) in a “triple bond metathesis”, rendering this reaction thermodynamically feasible.^[111] Besides, generation of amines by hydrogenation of an alkylimido complex represents an interesting target reaction.

Therefore, C-N bond formation will be focused. The formed imido complexes must be characterized and transformed into amines by hydrogenation or to nitriles. Possible strategies for the latter reaction type have been demonstrated by *Cummins* and *Tuczek*.^[110,112,132,192] Envisaged is not only the extrusion of the formed nitrile, but also the recovery of the starting material to close a synthetic cycle. Such a cycle comprising N₂ splitting, functionalization and liberation of N-containing molecules represents the final goal of all efforts.

II Results and discussion

1 Re(III) starting platform

1.1 (PNP^{tBu})ReCl₂

Parts of this chapter were published in the *Journal of the American Chemical Society* under the title: “Dinitrogen Splitting and Functionalization in the Coordination Sphere of Rhenium” in 2014.^[193]

Precursor for the (PNP)Re(III) platform is the Re(V) complex Re(O)(Cl)₃(PPh₃)₂ (**1**), which can easily be prepared from commercially available Re₂O₇ or KReO₄.^[194] Reduction of these oxo-complexes with excess PPh₃ in the presence of acetonitrile leads to the Re(III) precursor Re(Cl)₃(PPh₃)₂(NCMe) (**2**).^[195] As ligand, the PNP pincer bridged by ethylene groups with *tert*-butyl substituents on the phosphorous atoms was chosen. As the aim was to synthesize an electron rich, coordinatively undersaturated species, the electronic donor properties of this ligand as well as the steric shielding of the substituents was thought to be beneficial. Accordingly, addition of pincer ligand ^HPNP^{tBu} to the Re(III) precursor **2** in THF solution together with a base (NEt₃) affords highly air sensitive, violet (PNP)ReCl₂ (**3**) after 2 h at reflux in high yield. Without a base, no selective reaction could be observed. In the following “PNP” without further indication always describes the monoanionic pincer ligand with *tert*-butyl substituents on the phosphorous atoms.

Scheme 45: Synthesis of Re(III) platform (PNP)ReCl₂.

On the NMR timescale, **3** exhibits C_{2v} symmetry, whereas in the crystal structure a distortion from both trigonal bipyramidal and square pyramidal geometry is observed ($\tau = 0.37$). The complex is diamagnetic in the ground state ($\delta(^{31}\text{P}) = -51.5$ ppm) attributed to the strong π -donor amide in the ligand backbone as indicated by the sum of bond angles around the nitrogen atom (360°) and the short Re–N distance ($1.923(7)$ Å).¹

Figure 14: Molecular structure of **3** in the crystal. ORTEP plot with anisotropic displacement parameters drawn at the 50% probability level. The C–H hydrogen atoms are omitted for clarity. Selected bond lengths [Å] and angles [°]: Re1–Cl1 2.331(2), Re1–Cl2 2.364(2), Re1–N1 1.923(7), Re1–P1 2.402(2), Re1–P2 2.407(3); N1–Re1–Cl1 109.7(3), N1–Re1–Cl2 140.8(3), Cl1–Re1–Cl2 109.49(9), P1–Re1–P2 163.04(9).

3 is thermodynamically stable (up to 110°C), but degrades quickly in the presence of moisture, oxygen or upon longer exposure (> 1 day) to chlorinated solvents (DCM). With acetonitrile as coordinating solvent, equilibrium formation was observed. Small amounts are tolerated (about 1-2 equivalents), whereas addition of 10 equivalents to a benzene solution of **3** yields a green precipitate, which reforms the violet starting material after separation and dissolution in THF. In a $\text{CD}_2\text{Cl}_2/\text{d}_3$ -Acetonitrile mixture, the formation of a diamagnetic species ($\delta(^{31}\text{P}) = -18$ ppm) displaying broadened signals in the ^1H -NMR, could be observed, that has not been fully characterized so far. However single crystals were obtained out of a benzene/acetonitrile/pentane solution, which confirm coordination of acetonitrile to **3** (Figure 15).¹ The Re– N_{MeCN} bond distance is elongated compared to the Re– N_{PNP} bond length ($2.074(2)$ and $1.901(2)$ Å respectively) and in agreement with an ordinary single bond. The Re– N_{PNP} bond distance is even slightly shorter than in **3** ($\Delta d = 0.02$ Å). The amide is still planar (sum of angles: 359°), but the acetonitrile ligand is a little bent (Re–N–C: $170.9(2)^\circ$), indicating some “push-pull” relation by π -donation from the PNP-amide in metal orbitals, which backdonate into C–N antibonding orbitals of the nitrile ligand. The $\text{C}\equiv\text{N}$

¹ X-Ray diffraction was performed by Dr. Christian Würtele.

bond distance of the latter (1.137(3) Å) is however slightly shorter than for free acetonitrile (1.157 Å).^[196]

Figure 15: Molecular structure of **3** coordinated by acetonitrile. ORTEP plot with anisotropic displacement parameters drawn at the 50% probability level. The C–H hydrogen atoms are omitted for clarity, except for the acetonitrile ligand. Selected bond lengths [Å] and angles [°]: Re1–Cl1 2.3681(6), Re1–Cl2 2.5058(6), Re1–N1 1.901(2), Re1–N2 2.074(2), Re1–P1 2.4415(7), Re1–P2 2.4184(7), N2–C21 1.137(3); N1–Re1–Cl1 105.23(7), Cl1–Re1–Cl2 89.57(2), Cl2–Re1–N2 83.90(6) N2–Re1–N1 81.48(9), P1–Re1–P2 165.48(2), Re1–N2–C21 170.9(2).

1.2 (^HPNPⁱPr)ReCl₃

The sterically less demanding *iso*-propyl derivate of the PNP ligand is well examined in our group^[197–200] and prepared in a straightforward synthesis. To test, if the steric bulk is indeed a prerequisite for the synthesis of **3**, its application in the rhenium system was tested.

Heating a mixture of the free ligand ^HPNPⁱPr and the precursor complex **2** in THF to 70°C for 1 h leads to a clear green solution of the Re^{III} compound [(^HPNPⁱPr)ReCl₃] (**4**, Scheme 46).

Scheme 46: Synthesis of PNP^{iPr}-derivative **4**.

In agreement with an octahedrally coordinated complex with a d^4 electron count, the product shows paramagnetically shifted signals in the ^1H -NMR spectrum (Figure 16) and no ^{31}P -NMR signal. Interestingly, the observed signals are very sharp and even show some multiplet-like structure. One signal of the backbone protons is probably superimposed by the benzene signal and the amine proton is shifted far downfield ($\delta_{\text{H}} = 138.5$ ppm). Some diamagnetic impurities could not be removed and the complex has not been fully characterized yet.

Figure 16: ^1H -NMR spectrum of **4** in C_6D_6 .

In analogy to the synthesis of **3**, NEt_3 was added to the reaction mixture to deprotonate **4** in situ to a five coordinate dichloro species. However, no reaction was observed and also direct addition of NEt_3 to **4** does not lead to deprotonation.

Stronger bases were then tested. Deprotonation with 1 equiv. KBTSA or KO^tBu gives two diamagnetic signals ($\delta_{\text{P}} = -1$ and -18 ppm) in an about 2:3 ratio in the ^{31}P -NMR spectrum. However, these products have not been identified so far. Deprotonation employing 1,3,5-Triazabicyclo[4.4.0]dec-5-ene (TBD) as base results in selective formation of another product ($\delta_{\text{P}} = -6$ ppm), which still contains signals corresponding to TBD in the ^1H -NMR spectra after workup. Single crystals of this complex could be obtained and X-ray analysis revealed coordination of hexahydropyrimidinopyrimidine (hpp) to the rhenium complex (Figure 17).² TBD can be deprotonated to hpp, a bidentate ligand, forming the complex $[(\text{PNP}^{\text{iPr}})\text{Re}(\text{hpp})\text{Cl}]$ (**5**) upon elimination of two equivalents of HCl, although illustrating coordination and deprotonation of the PNP^{iPr} ligand (Scheme 47).

Scheme 47: Reaction of **4** with TBD generating **5**.

A disorder has been found in the unit cell of the crystal structure with a population of 0.878(2) on the main domain. The two substructures are quite similar and exhibit usual bond lengths. The $\text{Re}-\text{N}_{\text{PNP}}$ bond distance is comparable with **3** ($1.9193(17)$ Å) and the amide is also planar (sum of angles at N = 359.6° and 360.0°) in both substructures of **5**. However, the $\text{C}-\text{N}_{\text{PNP}}-\text{C}$ angle of the main structure ($115.7(4)^\circ$) is about $3\text{--}5^\circ$ larger than usually observed, whereas the same angle for the minor complex is particularly small ($98.5(6)^\circ$). Different refinement did not change this result significantly. Striking difference in both substructures is the opposite orientation of the two ^iPr -groups of the ligand backbone on the site of the chlorine atom. It seems like this orientation is compressing the backbone, leading to a smaller angle at the amide.

² X-Ray analysis was performed by Dr. Christian Würtele.

Figure 17: Molecular structure of **5**. ORTEP plot with anisotropic displacement parameters drawn at the 50% probability level. The C–H hydrogen atoms are omitted for clarity. Disorder depicted in grey. Selected bond lengths [Å] and angles [°]: Re1–N1 1.9193(17), Re1–N2 2.1499(15), Re1–N3 2.2143(15), Re1–Cl1 2.3860(15); N1–Re1–Cl1 111.63(5), N1–Re1–N2 99.91(7), N2–Re1–N3 59.53(6), P1–Re1–P2 169.22(8), P1A–Re1–P2 160.60(11), C9–N1–C1 115.7(4), C9A–N1–C1A 98.5(6).

1.3 (P=N=P)ReCl₂ and (P=NP)ReCl₂

The utilized PNP ligand provides the intriguing opportunity for functionalization of the alkylamido to enamido (P=NP) or dienamido (P=N=P) units (P=N=P = N(CHCHP^tBu₂)₂). By oxidation of the backbone, the ligand's rigidity as well as the π -donor properties of the amide can be fine-tuned.^[201] H-atom abstraction using the 2,4,6-tri-*tert*-butylphenoxy radical (PhO \cdot) proved to be the method of choice.^[202] Addition of benzoquinone or its derivatives in analogy to the iridium case only leads to complex degradation.^[203] Addition of 6 equiv. of PhO \cdot to the dichloro complex **3** results in full conversion to the divinyl compound [(P=N=P)ReCl₂] (**6**). Its ³¹P-NMR signal is slightly broadened (full width at half maximum (FWHM) = 0.12 ppm) and shifted far into the negative region ($\delta_P = -276$ ppm). Besides, also its ¹H-NMR (notably $\delta_H(\text{tBu}) = 2.6$ ppm, $\delta_H(\text{PCH}_2) = 0.9$ ppm, Figure 18) and ¹³C-NMR signals are rather unusual for these kinds of coordination compounds. This behavior indicates mixing in of paramagnetic excited states and therefore contribution of temperature independent paramagnetism (TIP).^[204] Identification of the corresponding signals in the NMR spectra has been accomplished by means of H,H-COSY and H,C-HSQC NMR spectroscopy. A paramagnetic side-product in varying amounts (5-20%) is observed ($\delta_H = 15.2$ ppm) in the reaction, which is tentatively assigned to [(P=N=P)ReCl₃] (**7**, Scheme 48). Control experiments suggest this assignment, as **7** can be prepared

independently from trichloro complex **23** (see chapter 4.3) by H-atom abstraction with PhO· (Figure 19) and can be converted cleanly into **6** by reduction with CoCp₂ (Scheme 49). The origin of the additional chloride could not be determined, as no other degradation products were observed by NMR spectroscopy and no chlorinated solvents or other additives were used.

Scheme 48: Reaction of **3** with excess PhO· to **6**, contaminated with **7**.

Figure 18: ¹H-NMR spectrum of **6** and small amounts of **7** in C₆D₆ after removal of 2,4,6-tri-tert-butylphenol by washing with pentane; Expansion: ³¹P{¹H}-NMR spectrum.

Scheme 49: Control experiments for the identification of **7**.

Figure 19: ^1H -NMR spectrum of the reaction mixture of **23** and $\text{PhO}\cdot$ in C_6D_6 .

If only 2-2.5 equiv. of $\text{PhO}\cdot$ are used, a C_1 symmetric species is observed in the NMR spectra, which corresponds to the enamido complex **8** with a chemical shift (^{31}P -NMR) in between the alkylamide **3** and the dienamido **6** (Figure 20). The constitution of **8** is supported by LIFDI mass measurements, but **8** could not be isolated as it is always contaminated either with **3** or **6** or both and they all show similar solubility properties. Further addition of $\text{PhO}\cdot$ generates **6** (Scheme 50).

Scheme 50: Reaction of **3** with $\text{PhO}\cdot$ to enamido **8** and dienamido **6**.

Figure 20: $^{31}\text{P}\{^1\text{H}\}$ -NMR spectrum of **3** with 2.5 equiv. of $\text{PhO}\cdot$ to form **8** in C_6D_6 .

In the following, this thesis focuses on the *tert*-butyl substituted ligand with the fully saturated ligand backbone (PNP).

2 Dinitrogen splitting

This chapter has been published partly in the *Journal of the American Chemical Society* under the title: “*Dinitrogen Splitting and Functionalization in the Coordination Sphere of Rhenium*” in 2014.^[193]

2.1 Nitride synthesis

3 is rapidly reduced by 1 equiv. Na/Hg in THF. Under N₂ atmosphere, (PNP)Re(N)Cl (**9**) is obtained in 90% spectroscopic yield upon comparison (³¹P, ¹H, ¹³C NMR) with an original sample, prepared by reaction of the dichloro complex **3** with an azide source ([PPN]N₃). The use of ¹⁵N₂ afforded the ¹⁵N-nitride isotopologue ($\delta(^{15}\text{N}) = 371$ ppm, Figure 21), confirming N₂ as source for nitride formation. Accordingly, reduction of **3** with Na/Hg under argon only gives an intractable mixture of compounds by NMR, which were not further characterized, and no indication for the formation of the nitride. Nitride formation could also be observed after addition of the nitride transfer reagent Li[DBABH] to **3** (Scheme 51). Moreover, reduction of **3** with Co(Cp*)₂ under N₂ also gives the nitride with slightly lower yields up to 75%. A hydride complex is found as main side product ($\delta_{\text{P}} = 31.2$ ppm; $\delta_{\text{H}} = -9.28$ ppm), which did not incorporate deuterium upon use of d₈-THF, possibly pointing toward traces of water or CoCp₂* itself as origin for the reduced yield. However, to the best of our knowledge, this is the first report of well-defined N₂ splitting into nitrides, which allows the use of organometallic reducing agents as also utilized in protocols for catalytic ammonia generation.^[31,39,44]

Figure 21: ^{15}N -NMR spectrum of **9** in d_8 -THF obtained from $^{15}\text{N}_2$ ^[205] besides an impurity (-14.0 ppm (d , $J = 6.1$ Hz) and -80.9 ppm (d , $J = 6.1$ Hz)).

Scheme 51: Different synthetic routes to the nitride complex **9**.

The ^1H and ^{13}C -NMR spectra of **9** indicate C_s symmetry as expected for a square-pyramidal nitride complex. All efforts to grow single-crystals suitable for X-ray diffraction were unsuccessful. Computational modeling confirmed the square-pyramidal geometry with the nitride in apical position and a typical $\text{Re}\equiv\text{N}$ bond length (1.65 Å).^[105] The lack of a low-lying, vacant d-orbital results in the absence of $\text{Re}-\text{N}_{\text{PNP}}$ π -bonding with the pincer ligand, as expressed in a long bond distance (2.03 Å), pyramidal nitrogen coordination and high amide basicity (see below).

The nitride complex **9** was characterized by cyclic voltammetry (CV) in CH_2Cl_2 . A reversible redox wave was found at -0.13 V vs $\text{FeCp}_2/\text{FeCp}_2^+$ assignable to the $\text{Re}^{\text{V}}/\text{Re}^{\text{VI}}$ redox couple. At more positive potential, an irreversible second oxidation is observed. Comparison with the CV of protonated $[(^{\text{H}}\text{PNP})\text{Re}(\text{N})\text{Cl}]^+$ (synthesis and characterization see below) suggests the latter as decomposition product. Importantly, no reduction of the nitride was observed within the electrochemical window of the solvent.

Figure 22: CV of $(\text{PNP})\text{Re}(\text{N})\text{Cl}$ in CH_2Cl_2 (1 mM, 0.1 M $[\text{N}^n\text{Bu}_4][\text{PF}_6]$, RT, glassy carbon working electrode, scan rate 400 mV/s).

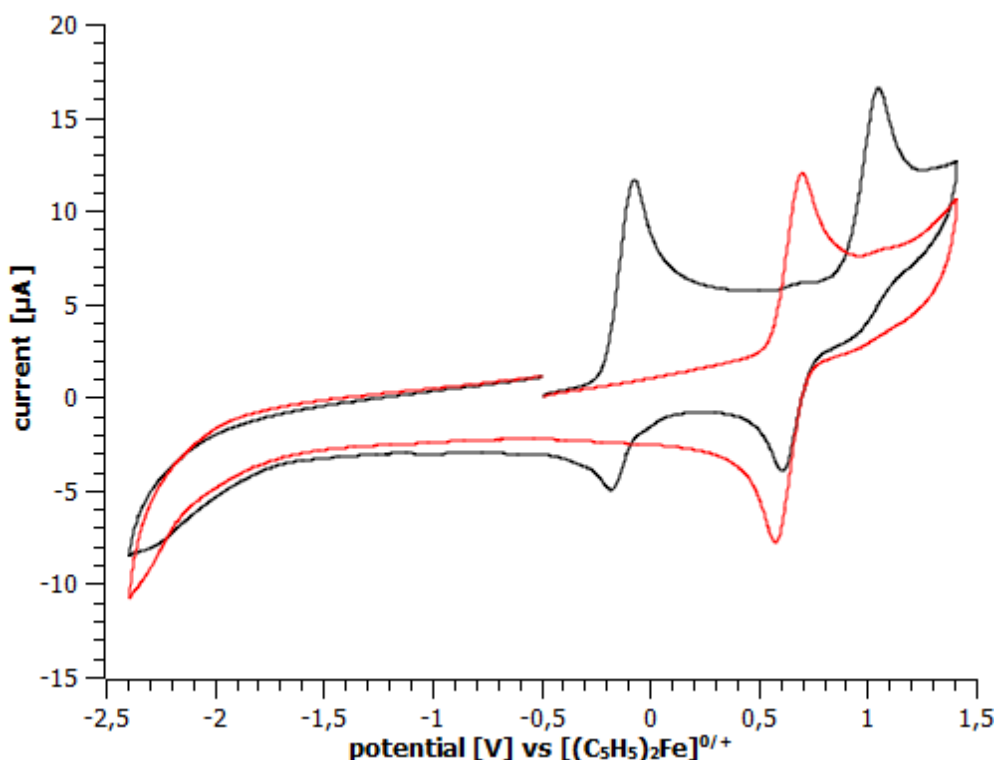

Figure 23: CVs of (PNP)Re(N)Cl (black) and [(^HPNP)Re(N)Cl]⁺ (red) in CH₂Cl₂ (1 mM, 0.1 M [NⁿBu₄][PF₆], RT, glassy carbon working electrode, scan rate 400 mV/s).

2.2 The Mechanism of N₂ Splitting

N₂ splitting with *Cummins'* Mo triamido system proceeds from a linear N₂-bridged dimer via a zigzag {Mo=N–N=Mo} transition state to the final nitrides.^[84,86,97,134,206] An analogous mechanism was proposed for reverse N–N coupling with [IrN(P=N=P)].^[156] Given the steric bulk of the Re(PNP) platform, a dimeric intermediate like [(PNP)ClRe(N₂)ReCl(PNP)] (**10**), which is formed upon reduction of **3**, represents a reasonable intermediate. While at the current stage no experimental mechanistic data are available, this pathway was evaluated computationally. For the dimer, both the triplet and an open-shell singlet states were found to be very close in energy. Both exhibit approximate square-pyramidal metal coordination and an almost linear {Re–N=N–Re} moiety (D_{NN} : 1.20 Å). A transition state towards N₂ cleavage could only be located on the singlet surface with a zigzag {Re=N–N=Re} conformation (D_{NN} : 1.64 Å). A moderate barrier has been found with $\Delta G^\ddagger = 84.4 \text{ kJmol}^{-1}$ and conformational

refinement could lower this barrier to $\Delta G^\ddagger = 71.4 \text{ kJmol}^{-1}$ later on (D3-PBE/def2-TZVP//def2-SV(P), Figure 24).³ N_2 cleavage was computed to be exergonic by 98.3 kJmol^{-1} , suggesting this route to be a feasible mechanism for dinitrogen splitting.⁴

Scheme 52: Proposed mechanism of N_2 -splitting by reduction of **3**.

Figure 24: Computed Free Energies for N_2 Splitting Starting from dimer **10** (D3-PBE/def2-TZVP//def2-SV(P)).

³ The PBE functional showed good performance in previous studies on PNP pincer nitride chemistry.^[176] A higher barrier ($\Delta G^\ddagger = 117.8 \text{ kJmol}^{-1}$) was found for a single-point calculation of the transition state with hybrid functional PBE0 (D3-PBE0/def2-TZVP//D3-PBE/def2-SV(P)), which is considered as an upper limit.

⁴ DFT Calculations were performed by Dr. Markus Finger.

Figure 25: Qualitative MO-scheme (left) and calculated MO's (right) for dimer 10.

The calculated MO's (Figure 25) fit well to the qualitative molecular orbital scheme, which has been introduced in Chapter I.5.1 (Figure 5). Because of fourfold symmetry, a set of basically non-bonding δ -orbitals (1b and 2b) is occupied. However, there are still a total of 10 electrons in the π -system of a tentative Re(II) dimer and therefore enough electrons for full N_2 reduction and generation of stable closed shell nitrides (Figure 26). The HOMO has been found to be the MN antibonding and NN bonding orbital, similar to *Cummins* system, mentioned in the introduction.

Figure 26: MO scheme for N_2 splitting from dimer **10** into **9**; blue: electrons in the {MNNM} π -system.

Because of the bulky t Bu-substituents on the PNP ligands, these are supposed to exhibit a staggered conformation in the dimeric complex (Scheme 52). A more symmetric arrangement with all phosphorous atoms in one plane cannot be adopted due to steric reasons. The π -donor amide is therefore interacting with both d_{xz} and d_{yz} orbitals (both orbitals of one MO set) in an equal manner, keeping the $2e_u$ level degenerate and therefore a triplet state dimer. In the zigzag transition state, symmetry is lowered, which allows for mixing of the σ -N-N-antibonding orbital $3b_u$ with the $2b_u$ π -orbitals. Transition of electrons is therefore possible and stable closed shell nitrides are created.

The fast splitting reaction without an observable N_2 -complex may partly be attributed to the influence of the π -donor in the ligand backbone. As stated by the group of *Cummins*, ligand rotation to allow for π -backbonding from one amide into the MO with π^* character of N_2 is believed to occur, lowering the barrier for splitting (Scheme 12). The PNP ligand already imposes such a geometry. Additionally, both orbitals of the $2e_u$ set are raised in energy due to the π -donor influence favoring “relaxation” in a zigzag confirmation. Additionally, steric repulsion between the bulky t Bu-groups is believed to support the N-N splitting reaction.

2.3 Possible implications of ligand variations

2.3.1 A decreased steric bulk

The steric bulk of the substituents at the phosphorous atoms is proposed to play an important role in the N_2 splitting mechanism. Because of the sterically demanding t Bu-groups, DFT calculations predict a twisted confirmation for the tentative N_2 -bridged intermediate dimer **10**, leading to an energetically rather high lying open shell singlet state. Splitting is then achieved via a triplet transition state to the nitride **9** on the singlet surface (Figure 27, black). If the steric demand was decreased for example by utilization of methyl-substituents, rotation of the $\{(PNP)ReCl\}$ fragments would be possible. In an inversion symmetric arrangement of the dimer, the amide in the ligand backbone N_{PNP} interacts with only one of the $2e_u$ orbitals, resulting in an energetic splitting of these orbitals and therefore formation of a closed shell singlet state dimer. Computations predict a strong stabilization of this dimeric species in the singlet state, with the triplet state being about 71 kJmol^{-1} higher in energy. In fact, this stabilization would even lead to a nearly isothermal splitting reaction with a quite high transition state ($\Delta G^\ddagger = 126.0 \text{ kJmol}^{-1}$, D3-PBE/def2-TZVP//def2-SV(P), Figure 27, blue).⁵

Figure 27: Computed Free Energies for N_2 Splitting Starting from dimer **10**; black: PNP^{tBu} , blue: PNP^{Me} (D3-PBE/def2-TZVP//def2-SV(P)).

⁵ DFT calculations carried out by Dr. Markus Finger.

Hence, there is the possibility to isolate such an N₂-bridged intermediate and to study its reactivity. Furthermore, confirmation of these computational results by experimental evidence provides an opportunity towards tuning of the N₂ splitting reaction energies and might even lead to catalytic N₂ activation.

However, in this thesis the focus lies on the first described system with the *tert*-butyl ligand system. Further work will examine the role of different substituents on the phosphorous atoms.

2.3.2 Oxidation of the ligand backbone

The π -donor strength of the amide in the ligand backbone is believed to have a significant influence on the N₂ splitting mechanism (*vide supra*) and lowering its strength should have an impact at least on the speed of the reaction. In this way an intermediate might be observed or even captured. Furthermore, the amide in the nitrido complex **9** displays strong basicity due to the lack of available d-orbitals for π -backbonding and protonation to $[(^H\text{PNP})\text{Re}(\text{N})(\text{Cl})]^+$ (**12**) is the pronounced reactivity (see next chapter). Delocalizing the amide's electron density over the ligand backbone offers a path towards more reactivity at the nitrido unit or at the metal center. By lowering the π -donor strength of the amide, d-orbital splitting at the metal is decreased, orbitals sink in energy and should therefore become available e.g. for H₂ coordination.

Preliminary reactivity tests towards N₂ splitting did not give definite results. **6** was converted to the nitrido compound **11** by addition of [PPN]N₃ to determine its spectroscopic signature ($\delta_{\text{P}} = 71$ ppm in C₆D₆). Afterwards, N₂ splitting was tested by reduction of **6** with 1 equiv. Na/Hg under N₂ atmosphere. Some small signals in the region around 60 ppm in the ³¹P-NMR spectrum were detected right after the reaction, which have vanished the day after and could perhaps correspond to some N₂ bridged intermediate (Figure 28). Only the very small signal in a similar region to **11** of the ³¹P-NMR spectrum is left and indicates that a nitride might have formed ($\delta_{\text{P}} = 67$ ppm in d₈-THF). However, isobutene formation and the lack of any bigger, distinct signals in the NMR spectra propose over-reduction by the strong reducing agent.

Figure 28: $^{31}\text{P}\{^1\text{H}\}$ -NMR spectrum of the reaction mixture of **6** with 1 equiv. Na/Hg under N_2 atmosphere about 10 min after the reaction in d_8 -THF.

The same reduction carried out under an atmosphere of argon does not show any ^{31}P -NMR signals and besides isobutene no characteristic signals in the ^1H -NMR spectrum.

A cyclovoltamogram of **6** has not been measured yet and no weaker reducing agents, like CoCp_2^* have been tested. As reduction of **6** is different under N_2 and argon atmosphere, a reaction with N_2 is likely to occur. However, more experiments are necessary to evaluate the outcome and the intermediates in this reaction.

3 Nitride functionalization

Parts of this chapter have been published in the *Journal of the American Chemical Society* under the title: “Dinitrogen Splitting and Functionalization in the Coordination Sphere of Rhenium” in 2014^[193] and in the *Journal Angewandte Chemie int. Ed.* under the title “Conversion of Dinitrogen into Acetonitrile under Ambient Conditions”.^[207]

3.1 Ammonia formation?

Our group recently reported hydrogenolysis of terminal nitride [Ru^{IV}(N)(PNP)] with H₂ to ammonia at mild conditions.^[176] In contrast, **9** does not react with H₂ even under more forcing conditions (3 bar H₂, 80°C, 18 h) or in the presence of base (KOtBu). Presumably, the strong nitride trans influence prevents H₂ heterolysis at the vacant site, due to the lack of available d-orbitals for coordination. These are involved in π -bonding to the nitride and therefore energetically augmented. Coordination at this site therefore seems to be hampered.

Protonation of the nitride with several acids (HCl, HOTf) results in exclusive protonation of the amido group giving [(^HPNP)Re(N)Cl]X (X = Cl, OTf) (**12**) even with up to 12 equiv HCl. DFT computations confirmed that amide over nitride protonation is thermodynamically favored by $\Delta G^0 = 31.9 \text{ kJmol}^{-1}$. The identical NMR data of **12-Cl** and **12-OTf** (except N–H) and the molecular structures from single-crystal X-ray diffraction indicate that the anions are not coordinated to the metal in solution and in the solid state.⁶ This observation reflects the strong nitrido trans influence and stabilizing N–H \cdots X hydrogen bonding. The Re ion in **12-Cl** is square-pyramidally coordinated with only minor distortion ($\tau = 0.04$) and a typical Re \equiv N triple bonding distance (1.642(4) Å).^[105]

⁶ X-Ray diffraction was performed by Dr. Christian Würtele.

Figure 29: Molecular structure of **12-Cl** in the crystal. ORTEP plot with anisotropic displacement parameters drawn at the 50% probability level. The C-H hydrogen atoms are omitted for clarity. Selected bond lengths [Å] and angles [°]: Re1-Cl1 2.4001(12), Re1-N1 2.132(4), Re1-N2 1.642(4), Re1-P1 2.4578(13), Re1-P2 2.4420(12); N1-Re1-Cl1 153.93(12), N1-Re1-N2 99.59(19), Cl1-Re1-N2 106.48(15), P1-Re1-P2 157.35(5).

In analogy to the parent nitride, the CV of **12-OTf** features a reversible oxidation wave, yet at more positive potential (+0.64 V, Figure 23) owing to the positive charge. Importantly, as for the neutral nitride, no reduction was observed. Chemical reduction with KC_8 only generated **9** and H_2 . Hence, the electrochemical results and reactivity indicate that the formation of ammonia seems not accessible on this route.

Although the cyclic voltammogram of nitride complex **9** did not show a reduction wave until a potential of -2.4 V vs. Fc/Fc^+ in DCM (Figure 22), chemical reduction with a very strong reducing agent (KC_8) proved to be possible. Addition of 2 equiv. of KC_8 and 2 equiv. of 18-crown-6 resulted in nearly complete disappearance of the spectroscopic signature of **9**. In benzene, the NMR spectra showed formation of a C_1 symmetric species in 80% yield ($\delta_{\text{P}} = 113.7$ ppm (d, $^2J_{\text{PP}} = 103$ Hz) and 30.1 ppm (d, $^2J_{\text{PP}} = 103$ Hz)), exhibiting only three signals for ^tBu -groups of the ligand backbone ($\delta_{\text{H}} = 1.82, 1.64$ and 1.22 ppm) with ^1H - ^{31}P coupling constants of 11.0 - 12.5 Hz (Figure 30). The fate of the fourth ^tBu -group is indicated by isobutene formation ($\delta_{\text{H}} = 4.8$ ppm (hept, $J = 1.2$ Hz) and 1.59 ppm (t, $J = 1.2$ Hz)). Upon reduction, it seems that one of the ^tBu -groups of the PNP ligand is eliminated, which is the reason for the low symmetry of the complex. The exact structure of this complex has not been identified though. About 10% of a side-product was formed ($\delta_{\text{P}} = 107.3$ ppm) and this amount increased to about 30%, when the reaction was carried out in THF instead of benzene (Figure 31) and which is a rather acceptable amount for further conversions. The complex exhibits signals in agreement with a C_s symmetric compound in the NMR spectra. In contrast to the asymmetric species described above, it features pentane solubility. However, this complex could not be isolated due to formation of different unidentified side-products. Reduction without ligand degradation would offer an interesting route towards functionalization of the nitride, but further experiments

(for example low temperatures) are suggested to identify the nature of these reaction products.

Figure 30: ^1H -NMR spectrum of the reduction of **9** with 2 equiv. KC_8 and 18-crown-6 in C_6D_6 ; Expansion: signals corresponding to isobutene formation.

Figure 31: $^{31}\text{P}\{^1\text{H}\}$ -NMR spectra of the reduction of **9** with 2 equiv KC_8 and 18-crown-6; Top: in d_8 -THF; Bottom: in C_6D_6 .

3.2 Reaction with nucleophiles

To test for reactivity towards nucleophiles, metal organyls were added to **9**. Addition of methyl lithium (MeLi) to the nitride **9** allows for quantitative exchange of the chloride substituent by a methyl group. In this way, the complex $[(\text{PNP})\text{Re}(\text{N})(\text{CH}_3)]$ (**13**) could be isolated and fully characterized.

Scheme 53: Synthesis of **13** from **9** and MeLi.

^1H and ^{31}P -NMR spectra of **13** are similar to **9**. A new signal corresponding to the methyl group appears at 2.32 ppm (t, $^3J_{\text{HP}} = 4.1$ Hz) in the ^1H -NMR spectrum with the appropriate signal at -17.6 ppm in the ^{13}C -NMR spectrum, indicating metal coordination (Figure 32).

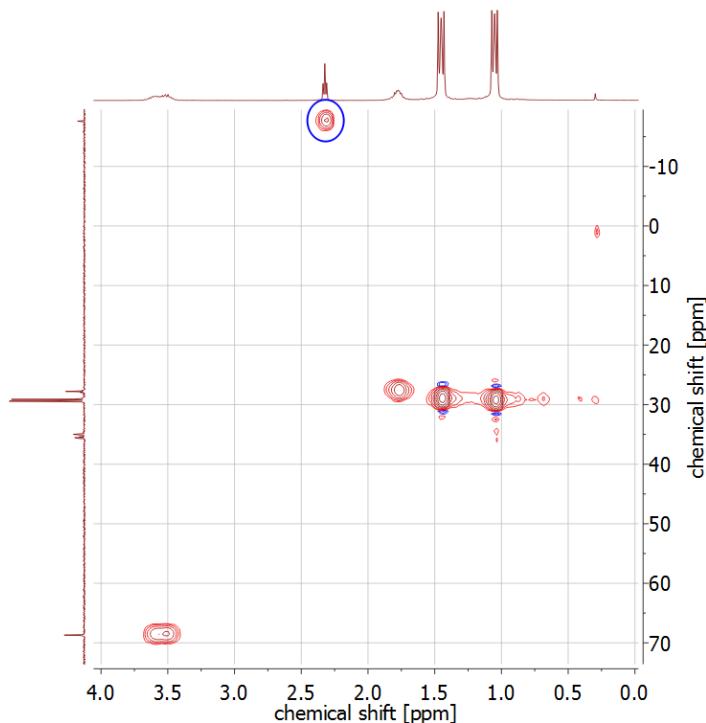

Figure 32: ^1H - ^{13}C HSQC NMR spectrum of **13**.

The solid state structure of the complex describes a square pyramid with the nitride in the apical position and only minor distortions ($\tau = 0.10$, Figure 33).⁷ The Re \equiv N bond length (1.656(5) Å) is in a typical range for terminal rhenium(V) nitrides.^[105] The Re-N_{PNP} bond length (2.054(4) Å) is elongated compared to most other {(PNP)Re} complexes and the nitrogen is pyramidally coordinated, as also predicted for **9** by DFT. In fact, the Re-N_{PNP} bond distance is only slightly shorter than in the protonated complex **12** ($\Delta d = -0.08$ Å), indicating only minor π -bonding between the amide and the metal center as it has been supposed for **9**. The ease of protonation of parent **9** is in agreement with this observation. Further reaction with a second equivalent of the metal organyl was not observed. Furthermore, **9** is stable in the presence of Grignard reagents (MeMgCl, *i*PrMgCl, PhMgBr) or hydride sources (LiHBET₃).

Figure 33: Molecular structure of complex **13** derived by single-crystal X-ray diffraction. ORTEP plots with anisotropic displacement parameters set at 50% probability. Hydrogen atoms are omitted for clarity. Selected bond lengths [Å] and angles [°]: Re1-N2 1.656(5), Re1-N1 2.054(4), Re1-C21 2.208(5), N2-Re1-N1 110.6(2), N1-Re1-C21 147.73(18), P1-Re1-P2 153.80(5).

⁷ X-Ray diffraction was performed by Dr. Christian Würtele.

3.3 Reaction with isonitriles

Introduction of a *trans*-substituent to the nitride at the rhenium center should increase nitride centered reactivity upon weakening of the $\text{Re}\equiv\text{N}$ bond strength. As coordination at this vacant site is proved to be hampered due to the strong *trans*-influence, strong ligands like isonitriles were investigated. To follow this approach, *tert*-butyl-isonitrile (CN^tBu) was added to a solution of **9**. A slow reaction yielding two diamagnetic, C_s symmetric main products in a 1:1 ratio is observed in ^1H and ^{31}P NMR spectra ($\delta_{\text{P}} = 94$ and 61 ppm), which is complete after 2 d at 70°C . Besides, characteristic signals for the formation of isobutene are observed in the ^1H -NMR spectrum. Since the elimination of a *tert*-butyl group as isobutene should be accompanied by H^+ release, the reaction was next carried out in the presence of DBU as base. The reaction is not accelerated, but turned out to be selective to one of the products observed before ($\delta_{\text{P}} = 94$ ppm), besides isobutene. After workup, the pentane insoluble material exhibits signals in the ^1H -NMR spectrum similar to the nitride **9** with no observable signals for a *tert*-butyl group of the isonitrile (Figure 34). Hence, elimination of its ^tBu -group as isobutene under HCl abstraction is assumed, generating the cyanide complex **14** (Scheme 54a). This type of dealkylation is known and has already been observed for ^tBu -isocyanide complexes.^[208,209]

Figure 34: Comparison of ^1H -NMR spectra of **14** (red) and **9** (green) in C_6D_6 .

Scheme 54: Assumed reaction of the nitride **9** with isonitrile and DBU as base to **14** (a) and of the protonated nitride **12-OTf** with isonitrile to **15** (b).

Addition of isonitrile to the protonated nitride **12-OTf** generates selectively the other product **15** ($\delta_P = 61$ ppm) with one singlet for the *tert*-butyl group of the isonitrile ligand in the $^1\text{H-NMR}$ spectrum in agreement with the above described observations (Scheme 57b). Complete characterization of the reaction products has not been carried out yet.

In this way, the chlorido ligand of **9** could easily be exchanged by a cyanido ligand in **14**. Furthermore, a reaction between **9** and isocyanides is demonstrated, illustrating that additional coordination to the nitrido complex is at least possible. However, these results point out that a ligand *trans* to the nitride is preferably avoided, unless the amide in the ligand backbone is protonated to an amine. The choice of another isocyanide, where its substituent is not as prone to elimination, might be able to activate the nitride moiety by coordination, at least as intermediate in further functionalizations.

3.4 Reaction with electrophiles

Typically early and mid TM nitrides react nucleophilic.^[105] In order to functionalize the nitride unit, **9** was converted with different electrophiles. The use of organohalides (MeI), acid chlorides (acetyl chloride), anhydrides (acetic anhydride, trifluoroacetic anhydride), aldehydes, silicon compounds (Me₃SiCl, Me₃SiBr, Me₃SiOTf), phosphines (PPh₃, PMe₃), CO₂ and CO did not result in any reaction with the nitride.

With an organic electrophile, such as an alkyl triflate, **9** reacts selectively at the nitrido ligand. Imido complex [Re(=NMe)Cl(PNP)]OTf (**16a**) is selectively formed with MeOTf (Scheme 55).^[193] Methylation of the nitrido, rather than the amido group of the PNP backbone is indicated by the absence of ¹H-NOESY crosspeaks with the pincer backbone protons (Figure 35) and confirmed by single crystal X-ray diffraction. The square-pyramidally coordinated Re ion ($\tau = 0.16$) in the imido complex exhibits a typical bond length (1.700(2) Å)^[105] to the slightly bent (168.31(17)°) methylimido ligand. The amido nitrogen features planar coordination, indicating N_{PNP} → Re π -donation, unlike in parent **9**. Importantly, DFT computations confirm that nitride over amide methylation is, in fact, favored by $\Delta G^0 = 33.2$ kJmol⁻¹, contrasting with the thermodynamic preference of protonation. *Caulton* and co-workers reported the same selectivity for electrophilic amide vs nitride attack in case of [RuN{N(SiMe₂CH₂P^tBu₂)₂}], which was attributed to steric effects.^[210]

Figure 35: $^1\text{H},^1\text{H}$ NOESY NMR spectrum of **16a**.

Figure 36: Molecular structure of **16a** in the crystal. ORTEP plot with anisotropic displacement parameters drawn at the 50% probability level. The C–H hydrogen atoms are omitted for clarity. Selected bond lengths [Å] and angles [°]: Re1–Cl1 2.4030(5), Re1–N1 1.9486(18), Re1–N2 1.700(2), Re1–P1 2.4776(6), Re1–P2 2.4450(6); N1–Re1–Cl1 141.23(6), N1–Re1–N2 115.58(9), Cl1–Re1–N2 103.14(7), P1–Re1–P2 150.99(2), Re1–N2–C21 168.31(17).

In analogy, the ethylimido complex **16b** is obtained upon reaction of nitride **9** with ethyl triflate (EtOTf) in essentially quantitative isolated yield (a = methyl-, b = ethyl-substituted, Scheme 55). Usually, the only observed side-product is protonated nitride **12**, which can be removed by washing with diethylether or crystallization out of toluene/ether. The NMR spectroscopic features of **16b** are close to **16a**, suggesting square-pyramidal geometry with the imide in the apical position as confirmed by X-ray diffraction for **16a** (Figure 36).^[207]

Scheme 55: Synthesis of imides **16-OTf** by addition of alkyl triflates to **9**.

Generation of the imides **16a/b-BF₄** can also be achieved using Meerwein salts [Me₃O][BF₄] or [Et₃O][BF₄].

To expand the reactivity scope to organotriflates containing π -systems, benzyl triflate was synthesized according to published procedures out of the respective organohalide (benzylbromide) and AgOTf and used *in situ*.^[211] Interestingly, the alkylation is only possible if a non-nucleophilic base (2,6-di-*tert*-butyl-2-methyl-pyridin) was added to the organotriflate mixture prior to the addition to **9**. Otherwise, the latter is almost quantitatively converted to the protonated species **12**, presumably due to the instability of the formed organotriflate. [(PNP)Re(NBn)(Cl)]OTf (**16c-OTf**, c = benzyl-substituted) is isolated in up to 60% yield and characterized by NMR spectroscopy and LIFDI mass spectrometry. The color of the complex and the chemical shift of its ³¹P-NMR signal ($\delta_P = 90$ ppm) is in the same region as for **16a** and **16b**. A singlet is observed for the benzylic NCH₂Ph group at 4.60 ppm in the ¹H-NMR spectrum (Figure 37), which shows coupling to the phenyl-groups in the aromatic region of the H,H-COSY-NMR spectrum (Figure 38). C-N bond coupling is indicated by NOESY cross peaks of the aromatic signals with the ^tBu groups of the PNP ligand as well as to the benzylic protons (Figure 39). The signals for the PNP-backbone have a similar chemical shift compared to the other imido complexes **16a/b**.

3. Nitride functionalization

Figure 37: ^1H -NMR spectrum of isolated **16c-OTf** in C_6D_6 .

Figure 38: $^1\text{H},^1\text{H}$ -COSY NMR spectrum of **16c-OTf** in C_6D_6 .

Figure 39: $^1\text{H},^1\text{H}$ -NOESY spectrum of **16c-OTf** in d_8 -THF.

Hence, N_2 splitting and functionalization of the resulting nitride in terms of C-N bond formation has been accomplished. The next step represents the cleavage of the Re-N bond and the release of nitrogen containing organic molecules.

3.5 Reaction with trifluoromethanesulfonic anhydride

The yield of the benzylation is acceptable (60% isolated), however far lower than the yield for methyl- and ethylation (almost quantitative). In an attempt to avoid the formation of **12** as main side-product, another procedure to prepare organotriflates was utilized. This procedure uses the respective alcohol, a non-nucleophilic base and trifluoromethanesulfonic anhydride (Tf_2O).^[212,213] Following this approach, the tentative organotriflate mixture was directly added to **9** without further workup. Intriguingly, **16c-OTf** was only observed in minor amounts in the resulting mixture with the main product being a new diamagnetic, C_s symmetric species ($\delta_P = 102$ ppm). A new signal was observed in the ^{19}F -NMR spectrum besides the triflate anion, indicating a reaction between **9** and Tf_2O . If the latter is purely added to **9**, the color of the solution immediately changes from yellow to green and selective formation of the new species is observed. Only signals for the ^tBu substituents and the ligand backbone are observed in the ^1H -NMR spectrum. Product identification was accomplished by single crystal X-ray analysis⁸ (Scheme 56) and LIFDI mass spectrometry, which allow an assignment as $[(\text{PNP})\text{Re}(\text{NTf})\text{Cl}]\text{OTf}$ (**17-OTf**). Unfortunately, due to strong disorder, the crystallographic resolution does not allow for description of bond lengths and angles. This product could be isolated in high yield (87%) from the reaction mixture.

Figure 40: ^1H -NMR and $^1\text{H}\{^{31}\text{P}\}$ -NMR spectrum with selective phosphorous decoupling at 102 ppm of **17-OTf** in d_8 -THF.

⁸ Determination of the molecular structure was performed by Christian Volkmann.

Figure 41: Molecular structure of complex **17-OTf** derived by single-crystal X-ray diffraction. ORTEP plots with anisotropic displacement parameters set at 50% probability. Hydrogen atoms are omitted for clarity.

Heating a solution of **17-OTf** in benzene (50°C, 3 days) or toluene (100°C, 18 h) results in selective formation of the protonated nitride **12-OTf**. The fate of the triflyl-group is indicated by ^{19}F -NMR spectroscopy, which shows for benzene one ($\delta_{\text{F}} = -62.4$ ppm) and for toluene three ($\delta_{\text{F}} = -61.5$ (39%), -62.1 (26%) and -62.3 ppm (35%)) new signals (Figure 42), which correspond to trifluoromethyl benzene (-64.0 ppm)^[214] and *ortho*-, *meta*- and *para*-trifluoromethyl toluene (-62.5 (para), -63.3 (meta) and -63.6 (ortho) ppm), respectively.^[215] Further analysis of this reaction e.g. by GC-MS has not been carried out yet.

Scheme 56: Reaction of **9** with Tf_2O to produce **17-OTf** and its presumed degradation in aromatic solvents.

Figure 42: $^{19}\text{F}\{^1\text{H}\}$ -NMR spectrum of **17-OTf** after heating to 100°C for 18 h in d_8 -toluene.

Addition of a base to deprotonate **12-OTf** back to **9** might enable a catalytic application of this reaction. However, this base must be stable under the reaction conditions and strong enough to deprotonate **12-OTf**. Catalytic trifluoromethylation of arenes and heteroarenes is a highly studied field especially in organic and pharmaceutical chemistry.^[216,217] Common cross-coupling reactions usually require stoichiometric reactants, harsh conditions and/or preactivated substrates and are in general catalyzed by late TM (Cu, Ag, Pd, Ni). Various CF_3 sources, which exhibit nucleophilic (e.g. Me_3SiCF_3),^[218] electrophilic (e.g. Umemoto's reagent)^[219] or radical reactivity (e.g. Langlois' reagent, NaSO_2CF_3) are known.^[220,221] Prefunctionalized (hetero)arenes, aryl halides and boronic acids are usually used with nucleophilic or electrophilic CF_3 reagents. Trifluoromethylation of non-activated arenes can be achieved by CF_3 radicals as shown for the first time by *MacMillan* in 2011, using photoredoxcatalysis with ruthenium complexes and $\text{CF}_3\text{SO}_2\text{Cl}$ as CF_3 source.^[222] Remarkable progress has been made recently by the groups of *Li* and *Mi*, which used TM free photocatalysis for trifluoromethylation of arenes, employing NaSO_2CF_3 .^[223] In this context, the observed CF_3 -group transfer reactivity of **17-OTf** is a novel contribution. Catalysis with mid/early TM is uncommon, only a base and Tf_2O are needed and the use of Tf_2O as CF_3 source has not been shown to the best of my knowledge. However, in first instance, it has to be clarified, if the observed trifluoromethylation is actually a thermally induced process or photoinduced and if the mechanism involves electrophilic $^+\text{CF}_3$ or $\cdot\text{CF}_3$ radicals.

Further preliminary reactivity tests of **17-OTf**, did not give any satisfactory results. With H₂ or alkenes, no reaction is observed. Hydrid sources (LiHBEt₃), Grignard reagents (MeMgCl) and phosphines (PMe₃) cause degradation in various signals in the ¹H- and ³¹P-NMR spectra. However, the easy functionalization with Tf₂O might offer a route to a more activated {ReN}-moiety and therefore allow different functionalizations of the nitrogen unit.

4 Conversion of Dinitrogen to Organonitriles

Parts of this chapter have been published in 2016 in the Journal *Angewandte Chemie int. Ed.* under the title: “Conversion of Dinitrogen into Acetonitrile under Ambient Conditions”.^[207]

4.1 Strategy for N₂ into organonitrile transformation

According to thermochemical arguments, nitriles are attractive targets as the formation of strong C≡N bonds ($D^0(\text{HC}\equiv\text{N}) = 937 \text{ kJmol}^{-1}$) facilitates offsetting the large N₂ bond energy (941 kJmol⁻¹).^[111] Cummins and co-workers reported elegant synthetic cycles for the six-electron transformation of N₂ to nitriles mediated by Mo and Nb complexes.^[110,132] The routes start with initial dinitrogen splitting,^[83] followed by nitride acylation with silyltriflate and acylchloride. Subsequent stepwise three-electron reduction requires further silyltriflate and Lewis acid (SnCl₂ or ZnCl₂) for oxygen removal with nitrile release in up to 38% yield over all five steps.^[110] In this synthetic scheme re-reduction of the (formal) catalyst is a purely metal-centered process (Scheme 57, a).

Scheme 57: Schematic pathways of nitrile synthesis after N₂-splitting and functionalization: Through nitride acylation established by Cummins et al. (a)^[110] or through nitride alkylation (b and c) evaluated herein.

This work was the inspiration to evaluate new ways of N_2 into nitrile conversion, which rely on intramolecular electron transfer: The interconversion of imido and nitrile ligands via 1-azavinylidenes (or ketimides) by simple double de/protonation was previously reported (Scheme 57, b), but not applied to N_2 fixation.^[192,224] Importantly, both deprotonation steps are associated with formal metal/ligand two-electron redox steps offering new strategies for metal reduction within a (pseudo)-catalytic N_2 functionalization cycle (Scheme 57, b and c). Following these strategies, in this chapter several routes for the conversion of N_2 into acetonitrile via rhenium-mediated N_2 splitting, nitride alkylation, and ligand oxidation are reported leading up to a synthetic cycle in three steps in over 50% yield per cycle.

4.2 Acetonitrile release by double deprotonation

In the previous chapter, dinitrogen splitting upon reduction of rhenium(III) pincer complex **3** with Na/Hg or $CoCp^*_2$ and alkylation of the resulting rhenium(V) nitride **9** to the imido complexes **16a-c-OTf** was reported. This chapter is focusing on the conversions of **16b-OTf**.

16b-OTf is deprotonated quantitatively with $KN(SiMe_3)_2$ (KBTSA) giving the respective red-brown 1-azavinylidene rhenium(III) complexes $[(PNP)Re(N=CHCH_3)Cl]$ (**18b**; Scheme 58). The synthesis of **18b** can also be carried out as a one-pot reaction directly from **9** by successive alkylation and deprotonation in benzene with almost quantitative spectroscopic and over 80% isolated yield.

Scheme 58: Alkylation of **9** and deprotonation of the resulting imide **16** to yield the azavinylidene species **18**.

Spectroscopic characterization of complex **18b** indicates the presence of two isomers in about 60:40 ratio with diagnostic 1H , ^{13}C , and ^{15}N NMR signals for the azavinylidene ligands, respectively (Figure 44). This observation is in line with the

formation of two stereoisomers as a result of hindered 1-azavinylidene rotation about the Re=N and N=C double bonds owing to strong Re \rightarrow N back bonding. The N=C double bond stretching vibration of the ketimide can be assigned to a weak band in the vibrational spectrum at 1594 cm⁻¹, which shifts by 22 cm⁻¹ upon ¹⁵N-labelling.

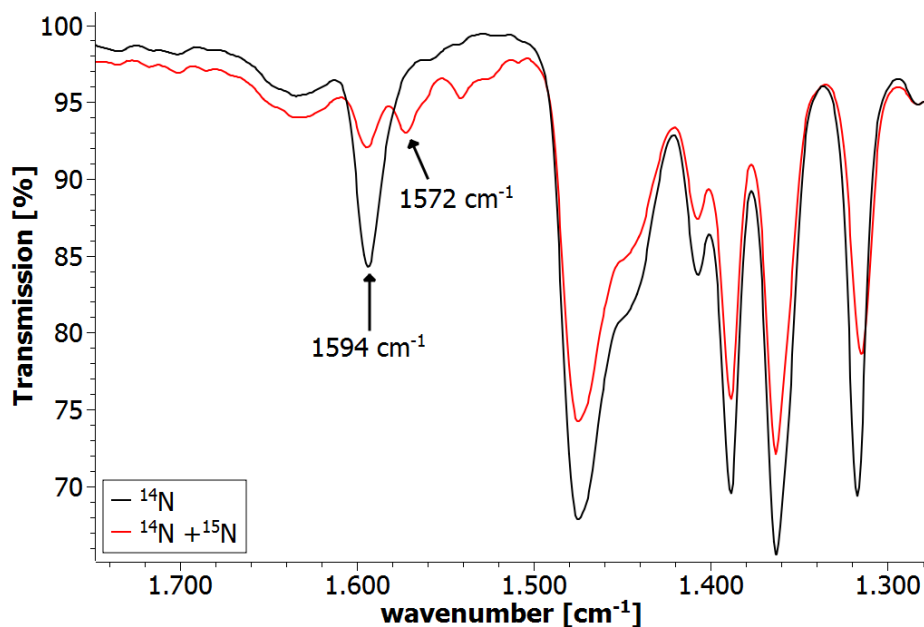

Figure 43: IR spectrum of **18b** (black) and 50% ¹⁵N labelled **18b-¹⁵N** (red) with bands assigned for $\nu(\text{C}=\text{N})$.

Figure 44: ¹H and ³¹P{¹H}-NMR spectra of the two isomers of **18b** in C₆D₆.

The structural assignment of **18b** is confirmed by single-crystal X-ray diffraction (Figure 45).⁹ The coordination geometry around the rhenium ion is close to that in the methylimide **16a** and all N-Re-N and N-Re-Cl bond angles of the two structures are the same within 5°. However, the almost linear Re-N-C moiety of **18b** exhibits considerably longer Re-N ($\Delta d = + 0.12 \text{ \AA}$) and shorter C-N ($\Delta d = -0.17 \text{ \AA}$) bonds than **16a**, in line with the changes in Re-N and C-N bond orders and with the only other structurally characterized rhenium 1-azavinylidene complex reported.^[225]

Figure 45: Molecular structures of complex **18b** derived by single-crystal X-ray diffraction. ORTEP plots with anisotropic displacement parameters set at 50% probability. Hydrogen atoms except for the azavinylidene ligand are omitted for clarity. Selected bond lengths [\AA] and angles [$^\circ$]: Re1–N1 1.948(5), Re1–N2 1.822(4), Re1–Cl1 2.3962(14), N2–C20 1.273(7), C20–C21 1.489(10); N1–Re1–N2 120.5(2), N1–Re1–Cl1 135.07(15), N2–Re1–Cl1 104.39(16), P1–Re1–P2 162.01(5), Re1–N2–C20 174.3(5), N2–C20–C21 125.7(7).

The ketimido complex **18b** can be further deprotonated if the resulting rhenium(I) ion is stabilized by strong π -acceptor ligands. For example, the reaction of **18b** with KBTSA and *tert*-butylisocyanide (CN^tBu , 2 eq) gives the bis-isonitrile complex $[(\text{PNP})\text{Re}(\text{CN}^t\text{Bu})_2]$ (**19**) immediately in almost quantitative yield with concomitant release of acetonitrile (Scheme 59, Figure 46). If no external base is added, the amide in the ligand backbone is protonated and the octahedrally coordinated tris-isonitrile complex $[(^{\text{H}}\text{PNP})\text{Re}(\text{CN}^t\text{Bu})_3]\text{Cl}$ (**20**) is generated in about 90% spectroscopic yield over the course of 10 days (Scheme 59). Two intermediates ($\delta_{\text{P}} = 58$ and 62 ppm) are observed during the reaction, but escaped further characterization (Figure 47). Heating of the reaction mixture (60°C) leads to degradation in several compounds. Besides the characteristic C_s symmetric signals in the $^1\text{H-NMR}$ spectrum of **20** (N-H: $\delta_{\text{H}} = 7.8$ ppm in C_6D_6 , three singlets for CN^tBu), the structural assignment could be verified by X-ray analysis (Figure 48).⁹ The crystallographic resolution however, does not allow for description of bond lengths and angles due to strong disorder.

⁹ X-ray diffraction was performed by Christian Würtele.

Scheme 59: Reactions of ethylazavinylidene **18b** with CN^tBu under different conditions.

Figure 46: Deprotonation of **18b** with $KN(SiMe_3)_2$ in d_8 -THF in the presence of CN^tBu (2.2 eq).

Figure 47: Time dependent $^{31}\text{P}\{^1\text{H}\}$ NMR spectra of the addition of excess CN^tBu to **18b** in C_6D_6 .

While **19** has C_{2v} symmetry in solution on the NMR time-scale, in the crystal (Figure 48) this compound features one strongly bent isonitrile ligand (C26-N3-C27: $134.2(4)^\circ$) while the other isonitrile remains almost linear (C21-N2-C22: $168.7(5)^\circ$).¹⁰ Such a strong bending is rare and indicates an unusually high degree of $\text{Re} \rightarrow \text{C}$ π -back bonding as a consequence of the electron-rich nature of the $\{(\text{PNP})\text{Re}^I\}$ fragment.^[226] Accordingly, the C26-N3 bond ($1.222(5) \text{ \AA}$) of the bent isonitrile is considerably longer than in the linear isonitrile moiety (C21-N2: $1.181(6) \text{ \AA}$).

¹⁰ X-ray diffraction was performed by Christian Würtele.

Figure 48: Molecular structures of complexes **19** (a) and **20** (b) derived by single-crystal X-ray diffraction. ORTEP plots with anisotropic displacement parameters set at 50% (a) and 30% (b) probability. Hydrogen atoms are omitted for clarity. Selected bond lengths [Å] and angles [°] for **19**: Re1–N1 2.028(3), Re1–C21 1.937(4), Re1–C26 1.906(4), C21–N2 1.181(6), C26–N3 1.222(5); N1–Re1–C21 131.76(15), N1–Re1–C26 140.30(15), Re1–C21–N2 171.9(4), Re1–C26–N3 168.9(3), C21–N2–C22 168.7(5), C26–N3–C27 134.2(4).

The electronic asymmetry is also resolved in the IR spectrum, which features bands in two regions at around 1960 cm^{-1} and 1760 cm^{-1} , respectively assignable to the linear and bent isonitriles (Figure 49). The low-energy stretching mode reflects the strongly reduced character of the bent isonitrile. Both bands are split into two, respectively, which can be rationalized with conformational isomers, as was previously reported for complexes with mixed linear/bent isonitriles.^[226]

Figure 49: IR spectrum of **19** (KBr pellet).

For completion, the reactivity of imido complex **16b-OTf** towards isonitriles was examined. As expected, in the presence of 2 equiv. of base, the bis(isonitrile) complex **19** is formed selectively, since the first equivalent of base deprotonates the imide to **18b**, which can be further deprotonated to **19** under release of acetonitrile (Scheme 59). However, CN^tBu also immediately reacts with the imido complex **16b-OTf** without a base. In a stoichiometric reaction, the selective formation of a new compound is monitored ($\delta_{\text{P}} = 33.6$ ppm). Curiously, a signal shifted rather to the high field region of the ^1H -NMR spectrum is observed ($d_{\text{H}} = -0.0$ ppm), which couples only to a doublet at a chemical shift of 3.9 ppm, as stated by COSY-NMR spectroscopy (Figure 50). These signals are assigned to a newly formed azavinylidene group. A broad signal in the low field region ($d_{\text{H}} = 6.0$ ppm) coupling to backbone protons, indicates protonation of the backbone nitrogen. It is assumed, that coordination of the isonitrile favors proton migration from the ethyl substituent to the amide N_{PNP} , generating $[(^{\text{H}}\text{PNP})\text{Re}(\text{NCHCH}_3)(\text{CN}^t\text{Bu})(\text{Cl})]\text{OTf}$ (**21**, Scheme 60). Although the complex is cationic, the comparatively high electron density is expressed by strong shielding and a considerable high field shift of the $\text{N}=\text{CH}-\text{R}$ proton.

Scheme 60: Formation of **21** and **20** upon addition of isonitriles to **16b**.

Structural confirmation could be obtained by X-ray diffraction (Figure 51). The bond lengths of the azavinylidene ligand are similar to **18**, however the $\text{Re}-\text{N}-\text{C}$ unit is slightly more bent (166.6° compared to 172.6° (**18a**) and 174.3° (**18b**)). The isonitrile ligand is bound linearly (179.6°) and the $\text{Re}-\text{C}$ bond length is a little elongated compared to the bis(isonitrile) complex **19** ($\Delta d = +0.1$ Å).

If further equivalents of isonitrile are added to **21**, degradation to **20** occurs with spectroscopic yields of 65% and formation of various side-products.

Figure 50: $^1\text{H},^1\text{H}$ -COSY-NMR spectrum of **21** in d_8 -THF.

Figure 51: Molecular structure of complex **21** derived by single-crystal X-ray diffraction. ORTEP plots with anisotropic displacement parameters set at 50% probability. Hydrogen atoms are omitted for clarity except for the azavinylidene ligand and the N-H proton. Selected bond lengths [\AA] and angles [$^\circ$]: Re1–N1 2.2020(11), Re–N2 1.8177(12), Re1–C23 2.0137(14), N2–C21 1.2785(18), C23–N3 1.1587(18); N1–Re1–N2 114.71(5) $^\circ$, N2–Re1–C23 84.59(5) $^\circ$, C23–Re1–Cl1 77.85 $^\circ$, N1–Re1–Cl1 82.84 $^\circ$, P1–Re1–P2 159.520(12) $^\circ$, Re1–C23–N3 179.56(14), Re1–N2–C21 166.60(12).

4.3 Acetonitrile release by oxidative functionalization

Intramolecular four-electron charge transfer from the ethylimido ligand to the metal by double deprotonation (Scheme 57b) is in fact feasible, if the electron-rich $\{(PNP)Re^I\}$ fragment is trapped by π -accepting ligands, such as isonitriles. However, regeneration of parent **3** on this route was unsuccessful, so far. Therefore, conversion of **18b** by oxidative functionalization of the azavinylidene ligand was examined. Cyclic voltammetry (CV) reveals reversible oxidation of **18b** at low potential ($E_0 = -0.58$ V) and irreversible oxidation beyond $+0.55$ V (Figure 52).

Figure 52: Cyclic voltammogram of complex **18b** (2 mM, DCM, 100 mV/s).

Accordingly, chemical oxidation with one equivalent of $AgPF_6$ in CH_2Cl_2 results in the formation of a red, paramagnetic product (Figure 53). While this compound could not be isolated due to slow degradation, in situ hydrogen-atom transfer (HAT) with 2,4,6-tri-*tert*-butylphenoxy radical (after preceding oxidation of **18b** with $AgOTf$) gives the vinylimido complex $[(PNP)Re(N-CH=CH_2)Cl][OTf]$ (**22-OTf**) in spectroscopic yields beyond 80% (Scheme 61). The vinyl substituent in **22** is unequivocally identified by its 1H -NMR signature (Figure 54), while the signals for the pincer ligand exhibit only small differences from those of the imido and ketimido complexes **16** and **18**. Notably, without preceding oxidation of **18b** (with $AgPF_6$ or $AgOTf$) no reaction is observed with 2,4,6-tri-*tert*-butylphenoxy radical.

Figure 53: $^1\text{H-NMR}$ spectrum of the $1e^-$ oxidation of **18b** with Ag^+ in CD_2Cl_2 .

Scheme 61: Synthesis of acetonitrile upon oxidation of N_2 -derived ketimide **18b**.

Hence, formal hydride abstraction from **18b** by stepwise one-electron oxidation and subsequent HAT favors the formation of an unusual rhenium(V) vinyl imide over the rhenium(III) acetonitrile tautomer (Scheme 62). This observation again emphasizes the distinct tendency of the electron-rich $\{(\text{PNP})\text{ReCl}\}$ core for $\text{M} \rightarrow \text{N}$ back bonding. However, the nitrile isomer $[(\text{PNP})\text{Re}(\text{NCMe})\text{Cl}]^+$ was computed to exhibit a triplet ground state that lies only around $\Delta G^0 = +16 \text{ kJmol}^{-1}$ higher in energy than **22**. This result suggests that acetonitrile elimination might be accessible on the rhenium(III) stage by trapping of the $\{(\text{PNP})\text{ReCl}\}^+$ fragment. Accordingly, the reaction of **22** with LiCl, crown ether (12-C-4) and substoichiometric amounts of 1,8-diazabicyclo[5.4.0]undec-7-ene (DBU) results in formation of parent **3** and acetonitrile, closing a full synthetic cycle. Without DBU no reaction is observed and

the non-nucleophilic base presumably facilitates proton transfer for vinyl-group tautomerization.

Scheme 62: Proposed equilibrium between **22** and its acetonitrile tautomer.

Figure 54: 1H -NMR spectrum of the synthesis of **22** from **18b** in C_6D_6 .

Albeit the spectroscopic yield in **3** and MeCN is only around 30% (internal 1H -NMR standard naphthalene, Figure 55) besides several other unidentified products, these results define the requirements for oxidative acetonitrile release from **18b**: A two-electron oxidant and a base for formal hydride removal in combination with a chloride source to stabilize rhenium(III).

To raise the overall yield of the synthetic cycle, several reagents were screened that fulfill the aforementioned requirements. For example, **18b** reacts with a mixture of $CuCl_2$ (2 eq) and DBU (1 eq) to give **3** in around 20% spectroscopic yield (^{31}P -NMR, Figure 56). The main product however turned out to be a C_1 symmetric species,

indicating an alteration of the ligand backbone. Not only the azavinylidene ligand is prone to oxidation, but also the CH₂ groups of the saturated ethylene bridges (see chapter II.2), which might occur under these reaction conditions. Best results were obtained using N-chlorosuccinimide (NCS) for oxidation. Reaction of **18b** with 2 eq NCS (Scheme 5) gives free acetonitrile in over 90% yield by ¹H-NMR (internal standard hexamethylbenzene, Figure 57).

Figure 55: ¹H-NMR spectrum of the release of acetonitrile from **22** with LiCl/12-C-4/DBU in d₈-THF.

Figure 56: $^{31}\text{P}\{^1\text{H}\}$ -NMR spectrum of the oxidation of **18b** with 2 eq CuCl_2 and 1 eq DBU in THF; Integrals are normalized to 100%.

Figure 57: ^1H -NMR spectrum of the reaction of **18b** with *N*-chlorosuccinimide (2 eq) in C_6D_6 (hexamethylbenzene as internal standard).

In addition, rhenium(IV) complex [(PNP)ReCl₃] (**23**) is obtained almost quantitatively according to comparison of the ¹H-NMR ($\delta_{\text{H}}(^t\text{Bu}) = 10.7$ ppm) and UV/Vis spectra with an authentic sample (Figure 58). Complex **23** was independently prepared by oxidation of **3** with 1 equivalent NCS and fully characterized. The molecular structure determined by single-crystal X-ray diffraction (Figure 59) reveals octahedrally coordinated rhenium with some distortion mainly arising from the pincer bite angle.¹¹ The magnetic moment in solution at room temperature from Evans' method (1.5 μ_{B}) is in agreement with a d³ low-spin configuration resulting from the strong pincer π -donation and some orbital contribution to the magnetic moment that leads to reduction of the magnetic moment with respect to the spin-only value. Contrariwise, EPR measurements did not show any signal. The facile synthesis of rhenium(IV) complex **23** from parent rhenium(III) dichloride **3** and NCS (1 eq) indicates that **3** could in fact be an intermediate in the oxidation of **18b** with NCS.

Figure 58: UV-vis spectra of isolated **23** in THF prepared by oxidation of **3** (red spectrum) and of **18b** (black spectrum) with *N*-chlorosuccinimide, respectively.

¹¹ X-ray diffraction was performed by Christian Würtele.

Figure 59: Molecular structures of complex **23** derived by single-crystal X-ray diffraction. ORTEP plots with anisotropic displacement parameters set at 50% probability. Hydrogen atoms are omitted for clarity. Selected bond lengths [Å] and angles [°]: Re1–N1 1.9038(16), Re1–Cl1 2.3893(5), Re1–Cl2 2.4024(5), Re1–Cl3 2.3700(5); N1–Re1–Cl1 91.50(5), N1–Re1–Cl2 178.69(5), N1–Re1–Cl3 91.59(5), P1–Re1–P2 160.046(16), Cl1–Re1–Cl2 88.090(17), Cl1–Re1–Cl3 176.471(16).

Finally, the synthetic cycle could be closed by reduction of **23** with Na/Hg (2 eq) under dinitrogen (1 bar) at room temperature (Scheme 63). The nitride **9** is obtained in over 70% spectroscopic yield (Figure 60). This full cycle of N₂ conversion into acetonitrile was further confirmed with a ¹⁵N-labeled sample producing ¹⁵N-labeled acetonitrile ($\delta_N = -129.9$ ppm). The reaction of **23** with only one equivalent of reductant (CoCp*₂) under argon quantitatively gives complex **3** as determined by ¹H and ³¹P-NMR spectroscopy, indicating that N₂-splitting starting from **23** might also pass through rhenium(III) complex **3** as an intermediate.

Scheme 63: Most efficient synthetic cycle for acetonitrile synthesis from N₂ with (PNP)Re complexes.

Figure 60: $^{31}\text{P}\{^1\text{H}\}$ NMR spectrum of the reduction of **23** with Na/Hg (2 eq) under N_2 (1 bar) at r.t.

In summary, the best synthetic cycle is composed of three simple reaction steps with 52% overall yield. A catalytic application is due to the need for both, strong electrophiles (EtOTf) and reducing conditions (Na/Hg) difficult. The solvent of choice to carry out the whole synthetic cycle in one pot has been found to be 1,4-dioxane, as it is sufficiently polar for the N_2 reduction step, but inert towards ring opening polymerization in contrast to THF. However, it was not possible so far to run the complete cycle a second time as no N_2 splitting could be achieved anymore in the presence of formed acetonitrile, succinimide, bis(trimethylsilyl)amine and KOTf.

4.4 Formation of benzonitrile

In analogy to the acetonitrile release by conversion of **16b-OTf**, the synthesis of benzonitrile from **16c-OTf** was envisaged to expand the reported synthetic cycle towards nitriles containing π -systems. **16c-OTf** displays the same reactivity as its ethyl analogue and can easily be deprotonated by KO^tBu or KBTSA to the azabenzylidene complex **18c** (Scheme 64). In the NMR spectra, **18c** also displays two sets of signals in the same region as observed for **18b** in agreement with two stereo isomeric structures. The benzylic protons displays small coupling to the phosphorous atoms ($^4J_{\text{HP}} = 2.0$ and 2.2 Hz) as usually observed for ketimido species **18**. Interestingly, some of the signals of the phenyl groups are broadened in the ^1H -NMR spectrum (Figure 61) and in contrast to the corresponding imide **16c-OTf** (Figure 38), no cross peaks between the phenyl groups and the benzylic protons are observed in the H,H-COSY NMR spectrum (Figure 62), which might indicate exchange of these protons. In the H,H-NOESY spectrum, spatial proximity between the phenyl groups and the ligand backbone is still observed by cross peaks (Figure 63).

Scheme 64: Synthesis of **18c** by benzylation of the nitride **9** with subsequent deprotonation and benzonitrile release upon reaction with NCS.

Figure 61: $^1\text{H-NMR}$ spectrum of **18c** in C_6D_6 .

Figure 62: $^1\text{H},^1\text{H-COSY}$ NMR spectrum of **18c** in C_6D_6 .

Figure 63: ¹H,¹H-NOESY NMR spectrum of **18c** in C₆D₆.

Single crystals of **18c** were examined by X-ray diffraction.¹² The asymmetric unit cell contained two complex molecules of **18c**, with one being disordered at one site of the PNP ligand backbone (Figure 64). The two structures are very similar and all bond length and angles are the same within 0.01 Å and 3.5° and describe a distorted square pyramide with the benzylidene group in the apical position ($\tau = 0.4$). Comparison with **18b** does not reveal any significant differences.

¹² X-ray analysis was performed by Dr. Christian Würtele.

Figure 64: Molecular structures of complex **18c** derived by single-crystal X-ray diffraction. ORTEP plots with anisotropic displacement parameters set at 50% probability. Hydrogen atoms are omitted for clarity, except for the azabenzylidene groups. Selected bond lengths [Å] and angles [°]: Re1-N1 1.938(2), Re1-N2 1.798(2), Re1-Cl1 2.3964(6), N2-C21 1.289(3), Re2-N3 1.944(2), Re2-N4 1.796(2), Re2-Cl2 2.3952(6), N4-C48 1.287(3); N1-Re1-N2 114.54(10), N1-Re1-Cl1 137.19(8), P1-Re1-P2 161.80(2), Re1-N2-C21 170.2(2), N3-Re2-N4 115.83(9), N3-Re2-Cl2 137.88(6), P3-Re2-P4 161.62(2), Re2-N4-C48 173.7(2).

In analogy to the release of acetonitrile,^[207] the reaction with 2 equiv. NCS generates signals corresponding to benzonitrile in about 50% spectroscopic yield (based on ¹H-NMR integration with hexamethylbenzene as internal standard) with concomitant formation of **23** (Scheme 64). A synthetic cycle for benzonitrile generation out of N₂ is therefore possible with an overall yield of about 13%. However, these are preliminary results as full characterization of **16c-OTf** and **18c** as well as ¹⁵N-labelling experiments have not been carried out yet. Nevertheless, the N₂ functionalization route is not only limited to alkyltriflates, but can also be used for π-conjugated systems.

In summary, these results describe a new strategy for dinitrogen functionalization to valuable chemicals beyond ammonia, which still represents a rare reaction type. Besides the thermochemical attractiveness of forming C≡N triple bonds after N₂ splitting, this work also offers mechanistic implications regarding the restoration of low-valent rhenium after N₂ splitting. As demonstrated, the alkylimide to nitrile ligand oxidation can be partially coupled with metal re-reduction. Such proton-coupled metal–ligand redox processes are therefore of particular relevance for future efforts to design truly (electro-)catalytic variants of N₂ transformation to organic compounds.

5 Reactivity of the methyl-imido analogue

5.1 Deprotonation and characterization of the methyl-ketimide

In 2011, the group of Cummins demonstrated N_2 conversion to cyanide with the $Mo(N^tBuAr)_3$ system. After N_2 splitting, alkylation and deoxygenation in the presence of base, they could observe the formation of a cyanido complex (Scheme 19).^[112] HCN could not be detected.

In analogy to acetonitrile release of the ethyl-substituted complex **16b-OTf**,^[207] the question arose whether the formation of cyanides or HCN is possible from the methyl-substituted complex **16a-OTf**. Hence, the latter was deprotonated as described in the previous chapter and **18a** could be isolated in high yield (Scheme 65).

Scheme 65: Synthesis of methyl-ketimido complex **18a**.

The spectroscopic signature is similar to **18b** and **18c**, although there is only one isomer. Nevertheless, the two protons of the $N=CH_2$ group display two characteristic multiplets with coupling to each other ($^2J_{HH} = 4.8$ Hz) and to the phosphorous atoms ($^4J_{HP} = 2.4$ Hz). Single crystal X-ray analysis¹³ revealed also comparable bond lengths to **18b**, only the N2-C21 bond distance of the azavinylidene group is slightly shorter ($\Delta d = 0.03\text{-}0.04$ Å). The Re-N-C angle is still close to linear ($172.6(2)^\circ$), but the

¹³ X-ray analysis was performed by Dr. Christian Würtele.

structure around the rhenium center is more distorted. **18a** is best described as a heavily distorted square pyramide, with the chloride in the apical position ($\tau = 0.46$), whereas **18b** and **18c** display a similar geometry, but with the azavinylidene/azabenzylidene ligand in the apical position ($\tau = 0.45$ and 0.40 respectively).

Figure 65: Molecular structure of complex **18a** derived by single-crystal X-ray diffraction. ORTEP plots with anisotropic displacement parameters set at 50% probability. Hydrogen atoms except for the azavinylidene ligand are omitted for clarity. Selected bond lengths [\AA] and angles [$^\circ$]: Re1–N1 1.9563(15), Re1–N2 1.8365(16), Re1–Cl1 2.3775(5), N2–C21 1.248(3); N1–Re1–N2 134.81(7), N1–Re1–Cl1 117.51(5), N2–Re1–Cl1 107.67(5), P1–Re1–P2 162.140(16), Re1–N2–C21 172.56(16).

Since the objective is an oxidative functionalization of **18a** as it has been found for **18b**, the product was characterized by cyclic voltammetry. The cyclic voltammogram displays similar to **18b** a reversible and an irreversible oxidation wave, although the potentials are shifted to slightly higher values (Figure 66).

Figure 66: Cyclic voltammogram of **18a** vs Fc/Fc^+ in DCM (200 mV/s, GC-Working electrode, 0.1 M $[\text{N}^n\text{Bu}_4][\text{PF}_6]$).

Reversibility for the lower wave was proven by scanning only in the region from -1 to 0 V with different scan rates (Figure 67). The rather quasi-reversible behavior of this wave in the bigger potential window (Figure 66) is therefore attributed to the second, completely irreversible oxidation wave.

Figure 67: Cyclic voltammogram of **18a** vs Fc/Fc⁺ in DCM with different scan rates.

5.2 Oxidative functionalization of the methyl-ketimide

Chemical oxidation of **18a** with 1 equiv. Ag⁺ however does not generate a paramagnetic complex similar to **18b**. Instead, a mixture of diamagnetic complexes is formed with the main product exhibiting only a singlet for the N=CH₂ group in the ¹H-NMR spectrum (Figure 69, note: chloride exchanged by a methyl group: $\delta_{\text{H}}(\text{ReCH}_3) = 3.54$ ppm, $\delta_{\text{H}}([\text{ReNCH}_2])_2 = 2.78$ ppm) in contrast to parent **18a**. This behavior would be in agreement with a dimerization of the complex. Exchanging the chloride substituent of **18a** by a methyl group (**25a**, see below) followed by 1 e⁻ oxidation allowed for crystal growth and X-ray diffraction of the product **24** (Figure 68).¹⁴ The obtained structure confirmed the dimerization of the complex to form a {Re-N-CH₂-CH₂-N-Re} bridge, but unfortunately, due to disorder problems, the crystallographic

¹⁴ Determination of the molecular structure was performed by Dr. Christian Würtele.

resolution does not allow for description of bond lengths or angles. Since the reaction affords some side-products with similar solubility, **24** has not been fully characterized yet. It is assumed, that **18a** forms a radical upon oxidation, with couples with another formed radical at the CH₂-group (Scheme 66).

Scheme 66: Chloride exchange by a methyl group and dimerization of **25a** to **24** upon oxidation.

Figure 68: Molecular structure of **24** derived by single-crystal X-ray diffraction. ORTEP plots with anisotropic displacement parameters set at 30% probability. Anions omitted for clarity.

Figure 69: $^1\text{H-NMR}$ spectrum of **24** after crystallization in CD_2Cl_2 .

To verify the radical reactivity of oxidized **18a**, a trapping reaction was performed. The redox potential of the trityl cation ($^+\text{CPh}_3$) is high enough to oxidize **18a** (-0.11 vs Fc/Fc^+ in acetonitrile).^[227] The oxidized form then instantaneously couples with the so generated trityl radical ($\cdot\text{CPh}_3$) to form $[(\text{PNP})\text{Re}(\text{NCH}_2\text{CPh}_3)(\text{Cl})][\text{PF}_6]$ (**16d-PF₆**) (Scheme 67).

Scheme 67: C-C Coupling of **18a** with the trityl cation.

The spectroscopic yield ($^{31}\text{P-NMR}$ integration) is about 50%. The main side-product (40%) turned out to be **16a**, tentatively due to residual moisture in the trityl salt $[\text{CPh}_3][\text{PF}_6]$. That coupling indeed occurred was verified by 2D-NMR spectra. In the $^1\text{H-NMR}$ spectrum of the resulting mixture, a singlet at 4.52 ppm is assigned to the NCH_2CPh_3 group, since the spectroscopic signature of **16a** is known (NCH_3 at 2.86 ppm). HSQC in combination with DEPT135 spectra confirm this signal to be a CH_2 group (Figure 70). In the $^1\text{H-NOESY}$ spectrum, distinct coupling between this signal

and the aromatic signals of the phenyl substituents (NCH_2CPh_3) as well as one *tert*-butyl group of the PNP ligand can be detected (Figure 71).

No nucleophilic reactivity of the methylene unit towards carbon electrophiles (MeOTf) has been reported, so nucleophilic attack of **18a** at the trityl cation is unlikely.

Figure 70: HSQC spectrum of an about equimolar mixture of **16a** and **16d** in d_8 -THF; vertical trace is the DEPT 135 spectrum of the same reaction mixture.

Figure 71: ^1H -NOESY spectrum of a mixture of **16a** and **16d** in d_8 -THF.

Deprotonation of this mixture with KBTSA affords the compounds **18a** and **18d**. The ^{31}P -NMR signal for the latter is in a slightly different region as for all other azavinylidene species ($\delta_{\text{P}} = 41$ and 44 ppm). Interpretation of the ^1H -NMR spectrum is hampered due to excessive signal overlap.

Scheme 68: Deprotonation of **16d-PF₆** to **18d**.

However, single crystals of **18d** suitable for X-ray diffraction could be obtained. The structure is disordered in one arm of the PNP ligand, but illustrates the C-C coupling reaction upon oxidation (Figure 72). Interestingly, the geometry of this complex resembles more a square pyramid than all other azavinylidene complexes ($\tau = 0.33$), maybe due to steric reasons. All bond lengths are comparable to **18a-c**. Striking

difference is the Re-N-C angle of the azavinylidene unit ($164.55(15)^\circ$), which deviates significantly from linearity and about 10° from the angles observed for **18a-c**. This might be due to steric reasons, as the bulky phenyl groups are rather close to one of the ^tBu-groups of the PNP ligand. All other angles are within 5° similar to **18a-c**. Since **18d** has not been isolated, nitrile release has not been tested.

Figure 72: Molecular structure of complex **18d** derived by single-crystal X-ray diffraction. ORTEP plots with anisotropic displacement parameters set at 50% probability. Hydrogen atoms except for the azavinylidene ligand are omitted for clarity. Selected bond lengths [Å] and angles [°]: Re1–N1 1.9403(17), Re1–N2 1.8237(16), Re1–Cl1 2.4120(5), N2–C21 1.283(2), C21–C22 1.556(3); N1–Re1–N2 113.37(7), N1–Re1–Cl1 138.73(5), N2–Re1–Cl1 107.88(5), P1–Re1–P2 158.747(18), Re1–N2–C21 164.55(15).

Cyanide generation from **18a** by an oxidative approach similar to **18b** seems to be difficult, since the oxidized form is not stable at all. Addition of 2 equiv. NCS to a solution of **18a** however results in formation of **23**, verified by $^1\text{H-NMR}$ spectroscopic investigations as well as a LIFDI mass record of the reaction mixture. Nevertheless, the reaction is rather unselective, as also diamagnetic and paramagnetic side-products are detected in the NMR spectra ($^1\text{H-NMR}$: Figure 73). A yield for **23** could not be determined so far. Mass spectrometry does not show any cyanide containing complex. Contrariwise, absorption bands in the range of $2260\text{--}2220\text{ cm}^{-1}$ in the IR-spectrum of the dried residue of the reaction (Figure 74) indicate coordinated or substituted $\text{C}\equiv\text{N}$ (free $\text{CN}^- = 2076\text{ cm}^{-1}$).^[228,229] Further investigations are necessary to clarify the fate of the {CN} unit.

Figure 73: $^1\text{H-NMR}$ spectrum of **18a** with 2 equiv. NCS in C_6D_6 .

Figure 74: IR spectrum (KBr) of the dried residue of the reaction of **18a** with 2 equiv. NCS; Selected wavenumbers [cm^{-1}]: $\nu(\text{R-C}\equiv\text{N})$: 2259, 2224 (w); $\nu(\text{C=O})$ = 1763, 1709 (s).

6 Further reactivity of the imides and ketimides

6.1 Reaction with metal alkyls

Linear {M-N-R} imido moieties often display electrophilic reactivity.^[105] To verify, if generation of amides is possible, the imido complexes **16** were tested towards nucleophiles like lithium organyls or grignard reagents. However, no reactivity at the imido nitrogen has been observed. Instead, 2 equiv. of MeLi or MeMgCl deprotonate the imide and substitute the chloride ligand to generate [(PNP)Re(NCHR)(CH₃)] (**25**, Scheme 69). The structural parameters for **25a** are basically the same as for **16a** (Figure 75) and the NMR data is similar. The new Re-CH₃ group of **25a** displays a triplet in the ¹H-NMR spectrum at 2.2 ppm (³J_{HP} = 4.2 Hz) and a negative chemical shift in the ¹³C-NMR (-10 ppm). The same reaction starting from **16b** generates **25b**, identified by a similar spectroscopic signature. No further reactivity is observed if an excess of metal organyl is used.

Scheme 69: Reaction of **16** with 2 equiv. of metal organyl to **25**.

Figure 75: Molecular structure of complex **25a** derived by single-crystal X-ray diffraction. ORTEP plots with anisotropic displacement parameters set at 50% probability. Hydrogen atoms except for the azavinylidene and methyl ligand are omitted for clarity. Selected bond lengths [Å] and angles [°]: Re1–N1 1.9837(14), Re1–N2 1.8416(15), Re1–C21 2.1416(18), N2–C22 1.271(2); N1–Re1–N2 143.36(6), N1–Re1–C21 112.59(7), N2–Re1–C21 104.04(7), P1–Re1–P2 161.895(16), Re1–N2–C22 169.52(14).

The use of PhMgBr also leads to deprotonation of the imide with a spectroscopic signature similar to **18a**, but the resulting complex does not incorporate any aromatics, as observed by NMR spectroscopy. Only very small signals are observed in the aromatic region of the ^1H -NMR spectrum, pointing towards residual Grignard reagent. Unexpectedly, the spectra are not identical with **18a** (Figure 76). The main difference is described by the chemical shift of the two signals for the NCH_2 -group, which are shifted by about 0.6 ppm each to higher field. An exchange of the chloride substituent by bromide is most likely, but has not been examined in more detail yet.

Figure 76: ^1H -NMR spectrum of **18a** (green) and the resulting complex from deprotonation of **16a** with PhMgBr (red, signals integrated) in C_6D_6 .

6.2 Imide reduction

To further analyze the reactivity of the imido complexes **16**, cyclic voltammetry was carried out using **16a**. The resulting voltammogram exhibits two irreversible reduction waves at a potential of -1.8 and -2.1 V in THF vs Fc/Fc⁺ (Figure 77).

Figure 77: Cyclovoltammogram of **16a** (1 mM) vs Fc/Fc⁺ in THF (400 mV/s, GC-Working electrode, 0.1 M [NⁿBu₄][PF₆]).

Chemical 2 electron reduction of **16a** using 2 equiv. KC₈ in THF produces selectively one diamagnetic, C_s symmetric compound in about 90% spectroscopic yield ($\delta_P = 79$ ppm). This compound features the characteristic signals for a N=CH₂ group as well as a hydride signal at a chemical shift of -4.3 ppm (d₈-THF) in the ¹H-NMR spectrum. Hence, not only reduction from Re^V to Re^{III} took place, but also chloride abstraction and most likely β -hydrogen elimination to produce [(PNP)Re(NCH₂)(H)] (**26a**, Scheme 70). For **16b**, similar results are obtained, albeit the spectroscopic yield in **26b** is lower (60% based on ³¹P-NMR integration).

Scheme 70: Reactions to produce **26** by reduction of **16** and by hydrogenation of **25**.

To verify the structural assignment of the products, H_2 was added to **25** and formation of the same compound was achieved (Scheme 70), proving that there is no chloride left in **26**. After heating to 70°C for 18 h (**25a**), complete conversion is observed under release of CH_4 (Figure 78).

Figure 78: $^1\text{H-NMR}$ spectrum of the addition of H_2 to a solution of **25** in $d_8\text{-THF}$ after 18 h at 70°C .

6.3 Hydrogenation reactions

Hydrogenation of the imido complexes is an interesting goal, as it offers the possibility of amine generation out of N₂-derived complexes. A reaction of **16a** with H₂ gas is not observed, unless small amounts of MeOTf or HCl are present, indicating catalysis of protons or Lewis acids. A new product is formed thereby in spectroscopic yields of about 85% ($\delta_P = 66$ ppm). No signals in the negative region of the ¹H-NMR spectrum are observed, but deprotonation of this product with 2 equiv. KO^tBu yields **26** again. Hydride signals might therefore be suppressed (broadened) by exchange with H₂ gas or are located in the positive region of the spectrum. The product is assumed to be [(^hPNP)Re(NCH₃)(H)(Cl)]OTf (**27**), although full spectroscopic characterization is lacking (Scheme 71).

Furthermore, hydrogenation of **18** is slow and results in two products in an 1:1 ratio after heating to 80°C for several days. One of them is **26**, as compared with original spectra (e.g. from imide reduction, see above), indicating that HCl is eliminated. The other one is **27**, as compared with hydrogenation of **16**, pointing towards HCl addition (Scheme 71). Hence, **18** disproportionates upon hydrogenation into **26** and **27**. Accordingly, the hydrogenation is selective towards **26** in the presence of a base as the formed HCl is trapped. In the presence of HCl on the other hand, only **27** is observed, supporting the above stated assignments.

Scheme 71: Hydrogenation reactions of **16** and **18**.

Protonation of **26** is accomplished using 1 equiv. of HOTf, HBar^F₄ or NH₄PF₆ and yields the imido complex **28** (Scheme 72). Expected signals for an alkyl group as well

as one hydride signal ($\delta_{\text{H}} = -6.2$ ppm, CD_2Cl_2) are observed in the ^1H -NMR spectrum. The ^{31}P -NMR shift is similar to all other imido complexes ($\delta_{\text{P}} = 97$ ppm). Similar to **16**, hydrogenation of **28** is possible, if some residual acid is present forming a new C_s symmetric compound **29**. However, this reaction is much faster and takes only a few minutes indicated by color change from green to rose, compared to three days at 80°C for **16** to yield blue **27**. Presumably, the presence of the hydride as strong σ -donor enhances the electron density at the metal, which favors H_2 coordination and splitting. Moreover, also for **29**, no hydride signals in the negative region of the ^1H -NMR spectrum can be observed anymore, pointing towards exchange with gaseous H_2 , self-exchange or a positive chemical shift. Unfortunately, the product could not be isolated, since vacuum application led to partial back-reaction to **28**.

Scheme 72: Hydrogenation of **28**: Possibility of amine release?

Equilibrium formation between **29** and a polyhydride under an atmosphere of H_2 represents a viable route to generate amines. To verify this assumption, hydrogenation of **28-BAr^F₄** was carried out in the presence of an additional equivalent of HBAr^F₄ in order to protonate (and preferably precipitate) potentially formed amine. In this way, a reaction back to **28** by vacuum application would be hampered. As before, **29** formed selectively. However, after evacuation of the reaction mixture, the same product distribution of **29** and **28** was found. Therefore, amine generation out of hydrogenation of the N_2 -derived imido complexes has not been accomplished so far.

III Summary

To fulfill the task of rhenium mediated N₂ splitting, a low valent, coordinatively unsaturated rhenium pincer complex was synthesized. The synthesis of Re(III) complex **3** containing *tert*-butyl substituents on the phosphorous atoms is straightforward and achieved in good yields (usually around 80% isolated). The complex is indefinitely stable at room temperature under argon atmosphere and no reaction with N₂ is observed. On the other hand, reduction of this complex under N₂ atmosphere using Na/Hg or CoCp*₂ generates the nitrido complex **9** in high spectroscopic yields. Although no well resolved crystal structure of this complex was obtained, comparison of its spectroscopic signature with an authentic sample prepared from an azide source ([PPN]N₃) as well as ¹⁵N-labelling confirmed the existence of a terminal nitride. Spectroscopically, no intermediates could be detected. However, the splitting mechanism is proposed to proceed via a linear μ-η¹-η¹-N₂ dimer analogous to the mechanism observed by *Cummins*.^[83,84] DFT calculations predict this mechanism to be a feasible route with a broken symmetry singlet state dimer as reaction intermediate. During N-N splitting a *zigzag* transition state is reached with a moderate barrier, which cleaves into the nitride complexes. The N-N splitting process was calculated to be exergonic by about 98 kJmol⁻¹. A {MNNM}^{10π4δ} system is believed to play an important role for the N-N cleavage to take place and is therefore stated to be a prerequisite. This is in agreement with most other dinuclear systems, which also contain a 10π-electron system and which also reduce N₂ into metal nitrides.

The utilized PNP ligand allows for simple variations in order to probe the influence of steric bulk, rigidity and π-donor strength of the involved amide. As DFT calculations predict a lower steric bulk to impede N-N splitting and may allow for isolation of an N₂ bridged intermediate, the *iso*-propyl-derivative PNP^{iPr} was employed. A five-coordinate amide like **3** seems to be disfavored. Contrariwise, the octahedrally coordinated amine **4** is formed. However, the latter has not been used for N₂ splitting in this thesis. Oxidation of the ligand backbone to enamide **8** and dienamide **6** can easily be accomplished by H-atom abstraction. The nitride **11** is a stable species, but a preliminary N₂ splitting test from **6** did not unambiguously confirm, that cleavage is possible with these systems.

A reaction of the nitride complex **9** with CO, CO₂ or H₂ gas has not been observed. Protonation of **9** yields the amine, nitride **12-X**, which is protonated at the backbone nitrogen and not at the nitride functionality. However, the nitride was found to react nucleophilic. Functionalization in terms of N-C coupling was achieved by reaction with strong electrophiles like alkyl triflates or alkyl oxonium compounds (Meerwein salts) to generate the respective imido complexes **16-X**. Addition of Tf₂O generates the triflated compound **17-OTf**. Weaker electrophiles like alkyl halides, acid chlorides, silicon compounds or anhydrides do not show a reaction with the nitride.

Usually, coordination *trans* to the nitride is inhibited due to its strong *trans* influence. However, strong σ -donors, like isonitriles do show a reaction. CN^tBu in combination with a base presumably forms the cyanide complex **14**. The *tert*-butyl group of the isonitrile is thus eliminated as isobutene. With strong electrophiles like MeLi, chloride exchange by a methyl group to **13** could be observed. Grignard reagents or hydride sources do not react with **9**. Synthesis and found reactivity of **9** is summarized in Scheme 73.

Scheme 73: Synthesis of the nitride complex **9** by N_2 splitting from **3** with subsequent functionalizations.

17-OTf displays interesting reactivity upon heating in aromatic solvents. Clean generation of **12-OTf** is observed and CF_3 -group transfer to the solvent is assumed. By addition of a suitable base, a catalytic application would be an intriguing possibility, although this was not tested during the course of this thesis.

The imido complexes **16** can be deprotonated by KO^tBu or KBTSA to generate the respective azavinylidene species **18**. If the deprotonation is carried out with MeLi or MeMgCl, additionally substitution of the chloride by the methyl group is observed to yield **25**. Addition of H_2 to the latter leads to exchange of the methyl group by a hydride substituent in **26**. The complex **26a** can also be synthesized by 2 electron

reduction from **16a-OTf**. Reduction from **16b-OTf** to **26b** is possible, but not as selective. Protonation of the azavinylidene species **18** and **26** to the respective imido complexes **16** and **28** is possible, however excess acid can cause degradation. Protonation of **25** has not been tested. These transformations are summarized in Scheme 74.

Hydrogenation of the imides and the azavinylidenes is possible, but usually protonation at the backbone nitrogen and the generation of a hydride is observed and no reactivity at the N₂-derived nitrogen.

Scheme 74: Transformations of all characterized azavinylidene species.

With the objective of acetonitrile release from **18b**, deprotonation of the latter was tested. However, only in the presence of strong π -acceptors like isocyanides (CN^tBu) a stabilization of the Re(I) species was observed under release of the nitrile. In **19**, the high electron density is expressed by an unusual, but not unprecedented, bending of one isocyanide ligand due to strong π -backbonding. However, the starting material for N₂ splitting, complex **3**, could not be recovered from **19**. In a second step, deprotonation and 2 electron oxidation was combined in order to oxidize the resulting Re(I) directly back to Re(III). Oxidation and simultaneous H-atom abstraction resulted in formation of the vinyl compound **22-OTf** instead of acetonitrile. However, the nitrile could be liberated in low yields by addition of a chloride source under generation of **3**. Addition of a chlorinating agent (NCS) to **18b** resulted in formation of the trichloro complex **23** with concomitant release of acetonitrile. The latter can be reduced by one electron to **3** or by 2 electrons under N₂ atmosphere to yield **9**. In this way a synthetic cycle for the transformation of N₂ in acetonitrile is achieved with an overall yield of 52% (Scheme 75).

Scheme 75: Synthetic cycles for the conversion of N_2 into acetonitrile.

Oxidation of the azavinylidene analogue **18a** resulted in C-C coupling, indicating that the oxidized form is quite unstable. If only an oxidizing agent (Ag^+) is added to the reaction, the main product turned out to be the dimer **24**. In situ formation of the trityl radical by oxidation of **18a**, allowed for the detection of the C-C coupling product **16d**. Utilizing this radical reactivity may allow for further functionalizations of the N_2 -derived moiety.

Chlorination of **18a** by NCS seems to produce **23** as observed for **18b**. However, the reaction is not as clean and the fate of the $\{CN\}$ moiety is unclear.

In summary, rhenium mediated N_2 splitting in terminal nitriles could be achieved. A $\{MNNM\}^{10\pi}$ electronic configuration is assumed to be necessary to lead to N-N cleavage. Unfortunately, the nitride turned out to be rather stable with efficient $Re\equiv N$ π -backbonding. NH_3 could not be generated in any way. However, functionalization with strong electrophiles leads to C-N bond formation. Further conversion of these imides could be achieved to liberate acetonitrile carrying N_2 derived nitrogen. By recovering of the starting material, a synthetic cycle could be closed. The system still has potential for the generation of different nitriles or even cyanide. A truly catalytic process seems unlikely with this system, but an electro-catalytic application might be feasible. Furthermore, the ligand system offers the possibility of fine-tuning of the steric and electronic requirements to not only obtain more insights into the N_2 splitting mechanism, but also to achieve more reactivity at the formed nitrido unit.

IV Experimental details

1 Methods

1.1 General Methods

Inert Gas

All reactions with reagents sensitive to air or moisture were performed using standard Schlenk techniques under an atmosphere of argon or N₂ where indicated (both 5.0, *Linde* gas). H₂ gas (5.0) was passed through a steel coil cooled with liq. N₂ to freeze out all moisture. All glassware was pretreated in a KOH/isopropanol bath, neutralized with diluted HCl, washed with deionized water and heated to 120°C. Before utilization, the glassware was heated under applied vacuum and flushed with argon in three cycles. Solvents were added via steel cannulas and rubber septum or trap-to-trap transferred in the reaction vessel. Glass fiber filters (Whatman GF/B) attached to Teflon cannulas with Teflon band were used for standard filtrations. A glass frit (G4) was charged with hot celite (min. 24 h at 120°C) for filtration over celite. Dewar vessels cooled with isopropanol/N₂ *liq.* or dry ice baths were used for low temperature synthesis. All small scale experiments (< 20 μmol) were performed in *J-Young* NMR tubes.

Glove box

Small scale reaction work up and weighing of sensitive materials was carried out in a glove box of *MBraun* under argon atmosphere. The atmosphere was circulated through columns filled with activated carbon, copper catalyst and molecular sieves (4 Å) to remove traces of oxygen, moisture and solvents.

Solvents

Pentanes, benzene, THF, toluene, DCM and diethylether were passed through columns packed with activated alumina and/or molecular sieves in a solvent purification system of *MBraun*. Methanol, ethanol, isopropanol, acetone and DMSO were dried by stirring over molecular sieves. Triethylamine was distilled from KOH under argon. Acetonitrile was dried over CaH₂ and distilled under argon. Deuterated solvents were dried over Na/K-alloy (C₆D₆ and *d*₈-THF) or CaH₂ (CD₂Cl₂), distilled by trap-to-trap transfer *in vacuo*, and degassed by three freeze-pump-thaw cycles, respectively. All solvents were stored under argon atmosphere.

1.2 Analytical Methods

Elemental Analysis

Elemental analyses were obtained from the Analytical Laboratories at the Georg-August University (Göttingen, Germany) on an *Elementar Vario EL 3*.

NMR Spectroscopy

NMR spectra were recorded on a *Bruker Avance III 300*, *Bruker Avance III 400 MHz* or a *Bruker Avance DRX 500* spectrometer and were calibrated to the residual proton resonance of the solvent (C_6D_6 : $\delta_H = 7.16$ ppm, $\delta_C = 128.39$; d_8 -THF: $\delta_H = 3.58$ ppm, CD_2Cl_2 : $\delta_H = 5.32$ ppm). ^{31}P and ^{15}N NMR chemical shifts are reported relative to external phosphoric acid and nitromethane ($\delta = 0.0$ ppm), respectively. Signal multiplicities are abbreviated as: s (singlet), d (doublet), t (triplet), m (multiplet), br (broad).

Mass Spectrometry

Electrospray mass spectrometry was performed with a *Bruker HCT ultra ESI-MS* under N_2 atmosphere. LIFDI mass spectrometry was carried out on a *JEOL AccuTOF JMS-T100GCV* spectrometer. The sample solution was introduced to the spectrometer via a steel cannula from a vial with rubber septum under argon atmosphere.

IR Spectroscopy

IR spectra were recorded on a *Thermo Scientific Nicolet iZ10* Transmission spectrometer as nujol mulls between KBr plates or as KBr pellets. Spectra in liquid phase were measured in a cuvette containing KBr windows and sealed with teflon plugs. All sample preparation was carried out in a glove box. Signal intensities are abbreviated as: w (weak), m (medium), s (strong).

UV-Vis Spectroscopy

UV-Vis absorption spectra were recorded on a *Varian* Cary 300 Scan spectrophotometer with sealed UV-Vis cuvettes under argon atmosphere.

Cyclic Voltammetry

Cyclic voltammograms were recorded on an Autolab PGSTAT101 from *Metrohm* in a glove box. Measurements were performed in a freshly prepared 0.1 M [*n*Bu₄N][PF₆]-solution of either THF or DCM with glassy carbon working electrode, Ag/AgNO₃ reference electrode and Pt counter electrode. Original spectra were referenced against the [(C₅H₅)₂Fe]^{0/+} couple.

Magnetic Measurements

Magnetic moments were determined in THF at room temperature by Evans' method as modified by Sur and corrected for diamagnetic contribution.^[230,231] Therefore, the sample (ca. 5 mg) was weighed in a J-Young NMR tube and dissolved in a defined volume (ca. 0.500 mL) of d₈-THF and referenced against the signal of a sealed capillary of the same solvent. The difference in chemical shift of the residual proton resonance of the solvent and the sealed capillary was used for the calculation of the magnetic moment.

2 Reagents and starting materials

2.1 Commercially available reagents and starting materials

MeOTf and EtOTf (Alfa Aesar) were distilled and stored at -34°C over molecular sieves or MgSO₄. *N*-chlorosuccinimide (Acros), [Fe(C₅H₅)] and KOtBu (Sigma) were sublimed prior to use. PPh₃ (ABCR) was recrystallized out of ethanol. CN^tBu (abcr) was degassed and stored over molecular sieves. Trifluoromethanesulfonic anhydride (ChemPur), Di-*tert*-butylchlorophosphine, benzylbromide (Alfa), ¹⁵N₂, Lithium granula, [N(PPh₃)₂]Cl, KBTSA, TBD, NH₄PF₆, CoCp₂, CoCp₂*, BuLi (2.5 M in hexanes), PhMgBr (1 M in THF), MeMgCl (3 M in THF, Sigma Aldrich), MeLi (1.6 M/Et₂O, Acros), KF, NaN₃ (Merck), AgOTf, AgPF₆, KReO₄, HCl (2 M in Et₂O, abcr) and HOTf (abcr) were used as purchased.

2.2 Non commercially available reagents and starting materials

Following reagents and starting materials were not obtained commercially and were synthesized according to following literature:

| Compound | Literature |
|--|------------|
| Re(O)(PPh ₃) ₂ Cl ₃ (1) | [194] |
| Re(Cl) ₃ (PPh ₃) ₂ (NCCH ₃) (2) | [195] |
| Di(2-chloroethyl)trimethylsilylamine | [232] |
| Bis(di- <i>tert</i> -butylphosphinoethyl)amine (PNP) | [233,234] |
| KC ₈ | [235] |
| Na/Hg | [236] |
| [N(PPh ₃) ₂]N ₃ ([PPN]N ₃) | [234,237] |
| 2,3:5,6-Dibenzo-7-azabicyclo[2.2.1]hepta-2,5-diene (HDBABH) | [238] |
| 2,4,6-tri- <i>tert</i> -butylphenoxy radical | [239] |
| H[B{C ₆ H ₃ (CF ₃) ₂ }] ₄ (H[BAr ^F] ₄) | [240] |

3 Synthesis

3.1 Re(III) platform

3.1.1 (PNP)ReCl₂ (3)

Published route

Re(Cl)₃(PPh₃)₂(NCCH₃) (**2**) (220 mg, 0.256 mmol, 1 eq), ¹HNP (92.7 mg, 0.256 mmol, 1 eq) and NEt₃ (71 μL, 0.513 mmol, 2 eq) are suspended in THF (30 mL) and heated to reflux for 1 h, leading to a color change from yellow to dark brown-violet. The mixture is allowed to cool to room temperature and the solvent is removed *i. vac.* The crude product is consecutively extracted with benzene (3 x 10 mL) and pentane (10 x 10 mL), filtered, and the solvent is removed *i. vac.* After lyophilization (benzene), residual PPh₃ is sublimed off by heating to 80°C for 3 d at 30 mTorr. The product **3** is obtained as violet powder. Yield: 126 mg, 0.204 mmol, 79%.

Improved synthesis

[Re(Cl)₃(PPh₃)₂(NCCH₃)] (**2**) (1.025 g, 1.194 mmol, 1 eq), ¹HNP (504.7 mg, 1.396 mmol, 1.2 eq) and NEt₃ (331 μL, 2.388 mmol, 2 eq) are suspended in THF (50 mL) and heated to reflux for 2.5 h, leading to a color change from yellow to dark brown-violet. The mixture is allowed to cool to room temperature and the solvent is removed *i. vac.* The crude product is extracted with benzene (3 x 10 mL) and after evaporation of the solvent, the residue is washed with pentanes until the color changes from brown to violet (ca. 4 x 5 mL). After lyophilization (benzene), residual PPh₃ is sublimed off by heating to 80°C for 30 h at 30 mTorr. The product **3** is obtained as violet powder. Yield: 634.7 mg, 1.028 mmol, 86%.

Spectroscopic Characterization

¹H NMR (300 MHz, C₆D₆, [ppm]): δ = 1.54 (A₁₈XX'A'₁₈, N = |³J_{HP} + ⁵J_{HP}| = 6.0 Hz, 36H, P(C(CH₃)₃), 2.20 (A₂B₂XX'B'₂A'₂, N = |³J_{HP} + ⁴J_{HP}| = 6.0 Hz, ³J_{HH} = 6.6 Hz, 4H, NCH₂), 2.28 (m, 4H, PCH₂).

¹³C{¹H} NMR (75.5 MHz, C₆D₆, [ppm]): δ = 32.0 (A₆XX'A'₆, N = |²J_{CP} + ⁴J_{CP}| = 2.0 Hz, P(C(CH₃)₃), 36.7 (AXX'A', N = |¹J_{CP} + ³J_{CP}| = 6.9 Hz, PCH₂), 52.4 (A₂XX'A'₂, N = |¹J_{CP} + ³J_{CP}| = 7.7 Hz, P(C(CH₃)₃), 98.0 (AXX'A', N = |²J_{CP} + ³J_{CP}| = 4.1 Hz, NCH₂).

³¹P{¹H} NMR (121.5 MHz, C₆D₆, [ppm]): δ = -51.5 (s, P^tBu₂).

3.1.2 Synthesis of [HPNP^{iPr}ReCl₃] (4)

HPNP^{iPr} (2.2 mg, 6.8 μ mol, 1.1 eq) is dissolved in C₆D₆ and added to **2** (5.2 mg, 6.1 μ mol, 1 eq) in a J-Young NMR tube. The mixture is heated to 65°C for 2 h during which the suspension clears off. The solvent is reduced to about 0.1 mL and pentane is added (0.7 mL). After filtration, the residue is again washed with pentanes (2 x 0.7 mL). The residue is extracted with benzene and filtered over Celite. NMR-spectra show formation of paramagnetic **4**.

¹H NMR (300 MHz, C₆D₆, [ppm]): δ = -12.1 (m, 2H), -6.7 (m, 2H), -0.1 (m, 2H), 6.7 (m, 2H), 8.2 (m, 6H), 8.6 (m, 6H), 9.0 (m, 12H), 9.7 (m, 2H), 137.2 (s, 1H).

3.1.3 Deprotonation of [HPNP^{iPr}ReCl₃] (4)

KO^tBu or KBTSA:

To a solution of **4** (3.5 mg, 5.8 μ mol, 1 eq) in d₈-THF (0.5 mL) the respective base, KO^tBu (0.7 mg, 6.4 μ mol, 1.1 eq) or KBTSA (1.2 mg, 5.8 μ mol, 1 eq), is added. The solution turns dark brown immediately and the ³¹P-NMR spectra show formation of two diamagnetic products.

³¹P{¹H} NMR (121.5 MHz, C₆D₆, [ppm]): δ = -1.4 (s, 35%), -17.0 (s, 65%).

TBD (Synthesis of 5):

To a solution of **4** (3.5 mg, 5.8 μ mol, 1 eq) in C₆D₆ (0.5 mL) TBD (0.8 mg, 5.8 μ mol, 1 eq) is added, followed by a color change to grass green and selective formation of one compound. The solvent is evaporated and the residue is extracted with pentanes. After drying *i. vac.* the residue is dissolved in C₆D₆. Crystallization out of pentane confirmed the formation of **5**.

³¹P{¹H} NMR (121.5 MHz, C₆D₆, [ppm]): δ = -6.1 (s, PⁱPr₂).

3.1.4 Synthesis of [(P=N=P)ReCl₂] (6)

3 (40.0 mg, 64.8 μmol , 1 eq) and 2,4,6-tri-*tert*-butylphenoxy radical (101.6 mg, 388.6 μmol , 6 eq) are dissolved in benzene (5-8 mL) and warmed to 50°C until the color changes from blue to green (5 h). The reaction is then stirred for another 15 h at room temperature, before the solvent is evaporated and the residue washed with pentanes (3 x 2 mL). CoCp₂ (1.5 mg, 7.9 μmol , 0.12 eq) is added together with benzene (5 mL) and the reaction is stirred for 1.5 h before filtration and lyophilization. The brown powder is then heated to 85°C under reduced pressure (30mTorr) to sublime off residual CoCp₂. Pure **6** is obtained as brown powder. Yield: 28.0 mg, 45.6 μmol , 71%.

Spectroscopic Characterization

¹H NMR (300 MHz, C₆D₆, [ppm]): δ = 0.90 (d, ³J_{HH} = 6.4 Hz, 2H, PCHCH), 2.61 (A₁₈XX'A'₁₈, N = |³J_{HP} + ⁵J_{HP}| = 6.2 Hz, 36H, P(C(CH₃)₃), 3.65 (A₂B₂XX'B'₂A'₂, N = |³J_{HP} + ⁴J_{HP}| = 16.4 Hz, ³J_{HH} = 6.4 Hz, 2H, NCHCH).

¹³C{¹H} NMR (75.5 MHz, C₆D₆, [ppm]): δ = 34.7 (A₆XX'A'₆, N = |²J_{CP} + ⁴J_{CP}| = 2.5 Hz, P(C(CH₃)₃), 77.4 (A₂XX'A'₂, N = |¹J_{CP} + ³J_{CP}| = 9.5 Hz, P(C(CH₃)₃), 147.6 (AXX'A', N = |¹J_{CP} + ³J_{CP}| = 15.4 Hz, PCHCH), 212.4 (AXX'A', N = |²J_{CP} + ³J_{CP}| = 7.9 Hz, NCHCH).

³¹P{¹H} NMR (121.5 MHz, C₆D₆, [ppm]): δ = -275.6 (s, P^tBu₂).

Mass Spectrometry

LIFDI+ (toluene, m/z⁺): 613.1 (C₂₀H₄₀Cl₂NP₂Re⁺).

Elemental Analysis

| | | |
|--|---------|----------------------------|
| C ₂₀ H ₄₀ Cl ₂ NP ₂ Re (%) | calcd.: | C, 39.15; H, 6.57; N, 2.28 |

3.1.5 Synthesis of [(P=N=P)ReCl₃] (7)

23 (5.0 mg, 7.7 μmol , 1 eq) and 2,4,6-tri-*tert*-butylphenoxy radical (10.0 mg, 38.3 μmol , 5 eq) are dissolved in C₆D₆ (0.5 mL) and heated to 50°C for 18 h. NMR spectra show complete conversion to paramagnetic **7** together with the formation of 2,4,6-tri-*tert*-butylphenol.

Spectroscopic Characterization

^1H NMR (300 MHz, C_6D_6 , [ppm]): δ = -51.3 (br), 15.1 (br).

Mass Spectrometry

LIFDI+ (toluene, m/z^+): 648.0 ($\text{C}_{20}\text{H}_{40}\text{Cl}_3\text{NP}_2\text{Re}^+$).

3.1.6 Synthesis of [(P=NP)ReCl₂] (8)

3 (5.0 mg, 8.1 μmol , 1 eq) and 2,4,6-tri-*tert*-butylphenoxy radical (4.2 mg, 388.6 μmol , 2 eq) are dissolved in benzene (0.5 mL) and stirred for 18 h, before more 2,4,6-tri-*tert*-butylphenoxy radical (1.1 mg, 4.2 μmol , 0.5 eq) is added. After stirring for another 5 h, the solvent is evaporated and the residue washed with pentanes until the washing solution is colorless (5 x 0.3 mL). The green product **8** is obtained in 80% spectroscopic yield (^{31}P -NMR integration) next to starting material **3** (δ_{P} = -54.7 ppm, 9%) and **6** (δ_{P} = -278.7 ppm, 11%).

Spectroscopic Characterization

^1H NMR (300 MHz, C_6D_6 , [ppm]): δ = 1.68 (d, $^3J_{\text{HP}}$ = 11.8 Hz, 18H, $\text{PC}(\text{CH}_3)_3$), 1.78 (d, $^3J_{\text{HP}}$ = 11.8 Hz, 18H, $\text{PC}(\text{CH}_3)_3$), 2.36 ($A_2B_2XX'B'_2A'_2$, $N = |^2J_{\text{HP}} + ^4J_{\text{HP}}| = 6.8$ Hz, $^3J_{\text{HH}} = 6.6$ Hz, 4H, PCH_2), 2.63 ($A_2B_2XX'B'_2A'_2$, $N = |^3J_{\text{HP}} + ^4J_{\text{HP}}| = 6.7$ Hz, $^3J_{\text{HH}} = 6.6$ Hz, 4H, NCH_2 , partially superimposed), 4.31 (d, $^3J_{\text{HH}} = 6.7$ Hz, NCH), 6.31 (dd, $^2J_{\text{HP}} = 32.7$ Hz, $^3J_{\text{HH}} = 6.7$ Hz, PCH).

$^{31}\text{P}\{^1\text{H}\}$ NMR (121.5 MHz, C_6D_6 , [ppm]): δ = -107.3 (d, $^2J_{\text{PP}} = 283.3$ Hz, P^tBu_2), -113.7 (d, $^2J_{\text{PP}} = 283.3$ Hz, P^tBu_2).

Mass Spectrometry

LIFDI+ (toluene, m/z^+): 615.1 ($\text{C}_{20}\text{H}_{42}\text{Cl}_2\text{NP}_2\text{Re}^+$).

3.1.7 Synthesis of [(P=N=P)Re(N)Cl] (**11**)

[PPN]N₃ (6.5 mg, 11.2 μmol, 1.4 eq) is added to **6** (5.0 mg, 8.1 μmol, 1 eq) and the reactants are suspended in THF (0.5 mL). The mixture is stirred for 3 d at room temperature. NMR spectra show complete conversion to **11** (95%) and an undefined sideproduct (5%, ³¹P-NMR signal at 48.1 ppm).

Spectroscopic Characterization

¹H NMR (300 MHz, C₆D₆, [ppm]): δ = 1.18 (A₉XX'A'₉, N = |³J_{HP} + ⁵J_{HP}| = 7.0 Hz, 18H, PC(CH₃)₃), 1.49 (A₉XX'A'₉, N = |³J_{HP} + ⁵J_{HP}| = 7.2 Hz, 18H, PC(CH₃)₃), 4.29 (A₂B₂XX'B'₂A'₂, N = |³J_{HP} + ⁴J_{HP}| = 2.2 Hz, ³J_{HH} = 6.2 Hz, 2H, PCHCH), 7.00 (m, 2H, NCHCH).

³¹P{¹H} NMR (121.5 MHz, C₆D₆, [ppm]): δ = 71.8 (s, P^tBu₂).

Mass Spectrometry

LIFDI+ (toluene, m/z⁺): 592.0 (C₂₀H₄₀ClN₂P₂Re⁺).

3.2 Nitride synthesis and functionalization

3.2.1 [(PNP)Re(N)Cl] (**9**)

N₂-route A

Na/Hg (109.7 mg, 1 mol/L, 1 eq) is added to a solution of **3** (5.0 mg, 8.10 μmol, 1 eq) in d₈-THF (0.5 mL) in a J-Young-NMR tube under N₂-atmosphere (1 bar) and the mixture is shaken. The color changes from violet to brown-yellow over the course of about 5 minutes. ³¹P{¹H}-NMR spectroscopy indicates the full conversion of the starting material and formation of Re(N)Cl(PNP) (**9**) in 86% yield besides two unidentified side-products (82.1 ppm (12%), 54.9 ppm (2%)). The ¹H, ¹³C{¹H} and ³¹P{¹H} NMR spectra of **9** are identical with an analytically pure sample obtained on the azide route (see below).

The ^{15}N -labelled isotopomer $\text{Re}(^{15}\text{N})\text{Cl}(\text{PNP})$ **9** ^{15}N is prepared by adding **3** (10.0 mg, 16.2 μmol , 1 eq) in d_8 -THF (0.5 mL) under argon atmosphere to Na/Hg (240 mg, 1 mol/L, 1 eq) in a J-Young-NMR tube. The reaction mixture is frozen immediately and the atmosphere is replaced by $^{15}\text{N}_2$. The mixture is allowed to warm to room temperature while shaking.

Spectroscopic characterization

^{15}N NMR (50.7 MHz, d_8 -THF), [ppm]: $\delta = 370.6$ (s, ReN). $^{15}\text{N}_2$ displays a signal at -70.8 ppm.

N₂-route B:

In a J-Young-NMR tube **3** (5.0 mg, 8.10 μmol , 1 eq) and CoCp^*_2 (2.8 mg, 8.50 μmol , 1.05 eq) are dissolved in d_8 -THF (0.5 mL) under N_2 -atmosphere and shaken. The color changes immediately to green and a green precipitate forms. The mixture is shaken for 16 h to allow for complete conversion of the reducing agent. **9** is formed in 48% yield ($^{31}\text{P}\{^1\text{H}\}$ -NMR) besides one major (31.2 ppm (24%)) and several smaller (<5%) diamagnetic side products. Additionally, one paramagnetic compound (14 ppm, br) could be detected in the ^1H -NMR.

Azide route:

3 (300 mg, 0.486 mmol, 1 eq) and $[\text{N}(\text{PPh}_3)_2]\text{N}_3$ (310 mg, 0.534 mmol, 1.1 eq) are stirred in THF (20 mL) at room temperature. The color changes slowly from violet to brown and gas evolution is observed. The mixture is stirred for at least 24 h at room temperature and filtered before evaporation of the solvent. The residue is first extracted with benzene (3 x 10 mL), the solvent evaporated and the residue extracted with pentane (6 x 15 mL) and filtered over Celite. After evaporation of the solvent, the product is lyophilized out of benzene to obtain an orange solid, which is sufficiently pure for most syntheses. Yield: 182 mg, 0.305 mmol, 63%. For further purification, this product is extracted another time with pentane and acetonitrile and dried at 80°C for 1 d. Yield: 153 mg, 0.257 mmol, 53%.

An equimolar mixture of the $^{14}\text{N}/^{15}\text{N}$ isotopomers is prepared by employing $[\text{N}(\text{PPh}_3)_2]^+[\text{N}_2]^-$, which was synthesized from $[\text{N}(\text{PPh}_3)_2]\text{Cl}$ and $\text{Na}[^{15}\text{N}^{14}\text{N}_2]$.

Spectroscopic Characterization

^1H NMR (300 MHz, C_6D_6 , [ppm]): $\delta = 1.22$ ($\text{A}_9\text{XX}'\text{A}'_9$, $\text{N} = |^3\text{J}_{\text{HP}} + ^5\text{J}_{\text{HP}} = 6.6$ Hz, 18H, $\text{PC}(\text{CH}_3)_3$), 1.37 (m, 2H, PCH_2 , superimposed), 1.41 ($\text{A}_9\text{XX}'\text{A}'_9$, $\text{N} = |^3\text{J}_{\text{HP}} + ^5\text{J}_{\text{HP}} = 6.7$ Hz, 18H, $\text{PC}(\text{CH}_3)_3$), 1.61 ($\text{ABCDXX}'\text{D}'\text{C}'\text{B}'\text{A}'$, $\text{N} = |^2\text{J}_{\text{HP}} + ^4\text{J}_{\text{HP}}| = 3.8$ Hz, $^2\text{J}_{\text{HH}} = 14.4$ Hz, $^3\text{J}_{\text{HH}} = 7.7$ Hz, $^3\text{J}_{\text{HH}} = 10.8$ Hz, 2H, PCH_2), 3.08 ($\text{ABCDXX}'\text{D}'\text{C}'\text{B}'\text{A}'$, $\text{N} = |^3\text{J}_{\text{HP}} + ^4\text{J}_{\text{HP}}| = 1.6$ Hz, $^2\text{J}_{\text{HH}} = 10.9$ Hz, $^3\text{J}_{\text{HH}} =$

10.8 Hz, $^3J_{\text{HH}} = 5.4$ Hz, 2H, NCH₂), 3.69 (ABCDXX'D'C'B'A', N = | $^3J_{\text{HP}} + ^4J_{\text{HP}}$ | = 15.9 Hz, $^2J_{\text{HH}} = 10.9$ Hz, $^3J_{\text{HH}} = 7.7$ Hz, $^3J_{\text{HH}} = 1.8$ Hz, 2H, NCH₂).

$^{13}\text{C}\{^1\text{H}\}$ NMR (75.5 MHz, C₆D₆, [ppm]): $\delta = 25.7$ (AXX'A', N = | $^1J_{\text{CP}} + ^3J_{\text{CP}}$ | = 11.3 Hz, PCH₂), 28.9 (A₃XX'A'₃, N = | $^2J_{\text{CP}} + ^4J_{\text{CP}}$ | = 1.9 Hz, PC(CH₃)₃), 29.0 (A₃XX'A'₃, N = | $^2J_{\text{CP}} + ^4J_{\text{CP}}$ | = 2.0 Hz, PC(CH₃)₃), 35.5 (AXX'A', N = | $^1J_{\text{CP}} + ^3J_{\text{CP}}$ | = 8.0 Hz, PC(CH₃)₃), 36.3 (AXX'A', N = | $^1J_{\text{CP}} + ^3J_{\text{CP}}$ | = 10.6 Hz, PC(CH₃)₃), 72.0 (AXX'A', N = | $^2J_{\text{CP}} + ^3J_{\text{CP}}$ | = 3.5 Hz, NCH₂).

$^{31}\text{P}\{^1\text{H}\}$ NMR (121.5 MHz, C₆D₆, [ppm]): $\delta = 84.2$ (s, P^tBu₂).

$^{15}\text{N}\{^1\text{H}\}$ NMR (50.7 MHz, C₆D₆, [ppm]): $\delta = 369.0$ (s, ReN).

Mass Spectrometry

ESI (acetonitrile, m/z⁺): 596.03 (C₂₀H₄₄ClN₂P₂Re⁺), 597.03 (C₂₀H₄₅ClN₂P₂Re⁺), 602.28 (C₂₀H₄₄ClN₂P₂Re⁺ - CH₃CN).

Li[DBABH] route

HDBABH (1.6 mg, 8.1 μmol , 1 eq) is dissolved in THF (0.3 mL) and BuLi (1.6 M in hexanes, 5 μL , 1 eq) is added dropwise at -35°C. The cold reaction mixture is transferred to **3** (5.0 mg, 8.10 μmol , 1 eq) in cold THF (0.2 mL) in a J-Young-NMR tube and shaken for 1 h upon warming to room temperature. The solvent is exchanged by d₈-THF and shaken for another 27 h. $^{31}\text{P}\{^1\text{H}\}$ -NMR spectroscopy indicates selective formation of **9** in 66% yield.

By deprotonation of **12-OTf**

12-OTf (10.0 mg, 16.2 μmol , 1 eq) is dissolved in d₆-benzene (0.5 mL) and KO^tBu (1.8 mg, 16.2 μmol , 1 eq) in d₈-THF (0.1 mL) is added. The color immediately changes to yellow and **9** is formed quantitatively ($^{31}\text{P}\{^1\text{H}\}$ -NMR).

3.2.2 [(¹H)PNP]Re(N)Cl]X (**12**)

12-OTf: HOTf (2.9 μ L, 33.5 μ mol, 1 eq) is added to a solution of **9** (20 mg, 33.5 μ mol, 1 eq) in benzene (5 mL). The yellow solution immediately turns darker. After stirring for 20 h, the solution is evaporated to dryness and the residue washed with pentane (2 x 5 mL). Lyophilization out of benzene affords the product **12-OTf** as red-orange solid. Yield: 23.2 mg, 31.1 μ mol, 92%.

Spectroscopic Characterization

¹H NMR (300 MHz, C₆D₆, [ppm]): δ = 1.11 (A₉XX'A', N = |³J_{HP} + ⁵J_{HP}| = 7.7 Hz, 18H, PC(CH₃)₃, partially superimposed), 1.15 (A₉XX'A', N = |³J_{HP} + ⁵J_{HP}| = 7.3 Hz, 18H, PC(CH₃)₃, partially superimposed), 1.50 (m, 2H, PCH₂), 2.34-2.12 (m, 4H, NCH₂ and PCH₂ superimposed), 4.22 (m, 2H, NCH₂), 6.54 (br, 1H, HPNP).

¹³C{¹H} NMR (75.5 MHz, C₆D₆, [ppm]): δ = 25.0 (AXX'A', N = |¹J_{CP} + ³J_{CP}| = 11.5 Hz, PCH₂), 27.6 (A₃XX'A', N = |²J_{CP} + ⁴J_{CP}| = 2.3 Hz, PC(CH₃)₃), 28.2 (A₃XX'A', N = |²J_{CP} + ⁴J_{CP}| = 2.0 Hz, PC(CH₃)₃), 35.7 (AXX'A', N = |¹J_{CP} + ³J_{CP}| = 7.8 Hz, PC(CH₃)₃), 36.3 (AXX'A', N = |¹J_{CP} + ³J_{CP}| = 11.1 Hz, P(C(CH₃)₃), 65.3 (s, NCH₂).

³¹P{¹H} NMR (121.5 MHz, C₆D₆, [ppm]): δ = 69.4 (s, P^tBu₂).

Elemental Analysis

The deviation in the sulfur Analysis is attributed to the presence of fluorine.

12-Cl: A solution of HCl (2 M in ether, 4.1 μ L, 1 eq) in THF (0.5 mL) is added to **9** (4.9 mg, 8.2 μ mol, 1 eq) in a J-Young-NMR tube. The color of the solution turns from yellow to red-orange and a red precipitate forms. After removing the solvent *i. vac.* the residue is dissolved in CD₂Cl₂. The product **12-Cl** is obtained spectroscopically pure (¹H-NMR) in 98% yield.

Spectroscopic Characterization

¹H NMR (300 MHz, CD₂Cl₂, [ppm]): δ = 1.38 (A₉XX'A', N = |³J_{HP} + ⁵J_{HP}| = 7.5 Hz, 18H, PC(CH₃)₃), 1.54 (A₉XX'A', N = |³J_{HP} + ⁵J_{HP}| = 7.2 Hz, 18H, PC(CH₃)₃), 2.18 (m, 2H, PCH₂), 2.68-2.54 (m, 4H, NCH₂ and PCH₂ superimposed), 4.21 (m, 2H, NCH₂), 9.17 (br, 1H, HN(CH₂)₂).

$^{31}\text{P}\{^1\text{H}\}$ NMR (121.5 MHz, CD_2Cl_2 , [ppm]): $\delta = 71.0$ (s, $P^t\text{Bu}_2$).

12-PF₆: AgPF_6 (2.1 mg, 8.4 μmol , 1 eq) and **9** (5.0 mg, 8.4 μmol , 1 eq) are dissolved in CD_2Cl_2 (0.5 mL). The solution turns red-orange and a grey precipitate forms. Two broad paramagnetic signals can be detected in the ^1H NMR spectrum (5.8 ppm and 3.8 ppm) besides the formation of **12-PF₆**.

3.2.3 (PNP)Re(N)(CH₃) (**13**)

9 (24.0 mg, 40.3 μmol , 1 eq) is dissolved in benzene (10 mL) and a solution of MeLi (1.6 M in Et_2O , 50 μL , 80.5 μmol , 2 eq) is added. The mixture is filtered and the solvent evaporated before the residue is extracted with pentanes and filtered over celite. After removal of the solvent *i. vac.* the product **13** is lyophilized out of benzene. Yield: 15.8 mg, 27.4 μmol , 68%).

Spectroscopic Characterization

^1H NMR (300 MHz, C_6D_6 , [ppm]): $\delta = 1.05$ ($\text{A}_9\text{XX}'\text{A}'_9$, $N = |^3\text{J}_{\text{HP}} + ^5\text{J}_{\text{HP}}| = 6.3$ Hz, 18H, $\text{PC}(\text{CH}_3)_3$), 1.45 ($\text{A}_9\text{XX}'\text{A}'_9$, $N = |^3\text{J}_{\text{HP}} + ^5\text{J}_{\text{HP}}| = 6.5$ Hz, 18H, $\text{PC}(\text{CH}_3)_3$), 1.77 (m, 4H, PCH_2), 2.32 (t, $^3\text{J}_{\text{HP}} = 4.1$ Hz, 3H, ReCH_3), 3.52 (m, 2H, NCH_2 , partially superimposed), 3.59 (m, 2H, NCH_2 , partially superimposed).

3.2.4 Reaction with isonitriles

Reaction of 9 with CN^tBu

9 (5.0 mg, 8.4 μmol, 1 eq) is dissolved in C₆D₆ (0.5 mL) and CN^tBu (1 μL, 8.8 μmol, 1 eq) is added. The reaction mixture is stirred for several days (7 d) at room temperature to observe the formation of 2 products in the NMR spectra.

³¹P{¹H} NMR (121.5 MHz, C₆D₆, [ppm]): δ = 60.8 (42%, **15**), 83.2 (15%, **9**), 94.8 (43%, **14**)

Reaction of 9 with CN^tBu and base to 14

9 (5.0 mg, 8.4 μmol, 1 eq) is dissolved in C₆D₆ (0.5 mL) and CN^tBu (1 μL, 8.8 μmol, 1 eq) and DBU (1.3 μL, 8.4 μmol, 1 eq) are added. The reaction is heated to 60°C for 4 d before the solvent is evaporated and the residue washed with pentanes (3 x 0.5 mL). After extraction with benzene, the NMR spectra shows full conversion to **14**.

Spectroscopic Characterization

¹H NMR (300 MHz, C₆D₆, [ppm]): δ = 1.18 (A₉XX'A'₉, N = |³J_{HP} + ⁵J_{HP}| = 6.9 Hz, 18H, PC(CH₃)₃), 1.35 (A₉XX'A'₉, N = |³J_{HP} + ⁵J_{HP}| = 6.9 Hz, 18H, PC(CH₃)₃), 1.49 (m, 4H, PCH₂), 3.36 (m, 2H, NCH₂), 3.63 (m, 2H, NCH₂).

³¹P{¹H} NMR (121.5 MHz, C₆D₆, [ppm]): δ = 94.8 (s, P^tBu₂).

Reaction of 12-OTf with CN^tBu to 15

12-OTf (2.5 mg, 3.5 μmol, 1 eq) is dissolved C₆D₆ and CN^tBu (0.5 μL, 3.6 μmol, 1 eq) is added and the mixture is stirred for 2 d at room temperature.

Spectroscopic Characterization

¹H NMR (300 MHz, C₆D₆, [ppm]): δ = 0.75 (s, 9H, CN^tBu), 0.88 (A₉XX'A'₉, N = |³J_{HP} + ⁵J_{HP}| = 5.6 Hz, 18H, PC(CH₃)₃), 0.93 (A₉XX'A'₉, N = |³J_{HP} + ⁵J_{HP}| = 5.4 Hz, 18H, PC(CH₃)₃), 1.53 (m, 2H, PCH₂), 1.97 (m, 2H, PCH₂), 2.67 (m, 2H, NCH₂), 3.67 (m, 2H, NCH₂).

³¹P{¹H} NMR (121.5 MHz, C₆D₆, [ppm]): δ = 60.0 (s, P^tBu₂).

3.2.5 [(PNP)Re(NMe)Cl]OTf (16a-OTf)

9 (40.0 mg, 67.1 μmol , 1 eq) is dissolved in toluene (10 mL) and MeOTf (7.6 μL , 69.3 μmol , 1 eq) is added. The orange solution is heated to 40°C for 4 h whereupon the color changes to green. The solution is allowed to cool to room temperature, filtered, layered with pentane and crystallized at -32°C. The solid is filtered off, washed with pentane (2 x 5 mL) and dried in vacuo. **16a-OTf** is obtained as a green microcrystalline solid. Yield: 39.9 mg, 51.6 μmol , 77%.

Spectroscopic Characterization

^1H NMR (300 MHz, C_6D_6 , [ppm]): δ = 1.01 ($\text{A}_9\text{XX}'\text{A}'_9$, $\text{N} = |^3\text{J}_{\text{HP}} + ^5\text{J}_{\text{HP}}| = 6.9$ Hz, 18H, $\text{PC}(\text{CH}_3)_3$), 1.15 ($\text{A}_9\text{XX}'\text{A}'_9$, $\text{N} = |^3\text{J}_{\text{HP}} + ^5\text{J}_{\text{HP}}| = 7.2$ Hz, 18H, $\text{PC}(\text{CH}_3)_3$), 2.04 ($\text{ABCDXX}'\text{D}'\text{C}'\text{B}'\text{A}'$, $\text{N} = |^2\text{J}_{\text{HP}} + ^4\text{J}_{\text{HP}}| = 5.5$ Hz, $^2\text{J}_{\text{HH}} = 14.9$ Hz, $^3\text{J}_{\text{HH}} = 4.3$ Hz, $^3\text{J}_{\text{HH}} = 6.7$ Hz, 2H, PCH_2), 2.21 ($\text{ABCDXX}'\text{D}'\text{C}'\text{B}'\text{A}'$, $\text{N} = |^2\text{J}_{\text{HP}} + ^4\text{J}_{\text{HP}}| = 3.9$ Hz, $^2\text{J}_{\text{HH}} = 15.3$ Hz, $^3\text{J}_{\text{HH}} = 7.8$ Hz, $^3\text{J}_{\text{HH}} = 7.8$ Hz, 2H, PCH_2), 2.64 (s, 3H, NCH_3), 3.77 ($\text{ABCDXX}'\text{D}'\text{C}'\text{B}'\text{A}'$, $\text{N} = |^3\text{J}_{\text{HP}} + ^4\text{J}_{\text{HP}}| = 4.0$ Hz, $^2\text{J}_{\text{HH}} = 14.2$ Hz, $^3\text{J}_{\text{HH}} = 7.1$ Hz, $^3\text{J}_{\text{HH}} = 7.1$ Hz, 2H, NCH_2), 4.64 ($\text{ABCDXX}'\text{D}'\text{C}'\text{B}'\text{A}'$, $\text{N} = |^3\text{J}_{\text{HP}} + ^4\text{J}_{\text{HP}}| = 9.6$ Hz, $^2\text{J}_{\text{HH}} = 13.4$ Hz, $^3\text{J}_{\text{HH}} = 8.0$ Hz, $^3\text{J}_{\text{HH}} = 4.1$ Hz, 2H, NCH_2).

3.2.6 [(PNP)Re(NEt)Cl]OTf (16b-OTf)

Published procedure

9 (100 mg, 168 μmol , 1 eq) is dissolved in benzene (5-10 mL) and freshly distilled EtOTf (23 μL , 177 μmol , 1.05 eq) is added. The mixture is heated to 40°C for 18h under stirring before it is allowed to cool to room temperature. The solvent is removed i. vac. and the residue washed with pentanes (3 x 5 mL), followed by extraction with benzene (2 x 5 mL), filtration and lyophilization. Complex **16b-OTf** is obtained as green powder. Yield: 126 mg, 163 μmol , 97%, often contaminated with 3-6% of **12**, based on ^{31}P NMR integration.

Improved synthesis

9 (70.5 mg, 118 μmol , 1 eq) is dissolved in benzene (5-10 mL) and EtOTf (20 μL , 150 μmol , 1.2 eq) is added. The mixture is stirred at room temperature for 24 h, filtered and the volume reduced to about 2 mL under reduced pressure, before layering with diethylether (10 mL). After 1 d at room temperature, the solvent is filtered off and the residue washed with ether (2 x 4 mL). The pure product **16b-OTf** is lyophilized (benzene) and obtained as green powder (68 mg, 87.9 μmol , 78%).

Spectroscopic Characterization

^1H NMR (400 MHz, C_6D_6 , [ppm]): δ = 1.02 ($\text{A}_9\text{XX}'\text{A}'_9$, $\text{N} = |^3\text{J}_{\text{HP}} + ^5\text{J}_{\text{HP}}| = 7.0$ Hz, 18H, $\text{PC}(\text{CH}_3)_3$), 1.07 (t, $^3\text{J}_{\text{HH}} = 7.1$ Hz, 3H, NCH_2CH_3), 1.16 ($\text{A}_9\text{XX}'\text{A}'_9$, $\text{N} = |^3\text{J}_{\text{HP}} + ^5\text{J}_{\text{HP}}| = 7.2$ Hz, 18H, $\text{PC}(\text{CH}_3)_3$), 2.14 ($\text{ABCDXX}'\text{D}'\text{C}'\text{B}'\text{A}'$, $\text{N} = |^2\text{J}_{\text{HP}} + ^4\text{J}_{\text{HP}}| = 3.9$ Hz, $^2\text{J}_{\text{HH}} = 15.1$ Hz, $^3\text{J}_{\text{HH}} = 8.0$ Hz, $^3\text{J}_{\text{HH}} = 7.5$ Hz, 2H, PCH_2), 2.23 ($\text{ABCDXX}'\text{D}'\text{C}'\text{B}'\text{A}'$, $\text{N} = |^2\text{J}_{\text{HP}} + ^4\text{J}_{\text{HP}}| = 5.7$ Hz, $^2\text{J}_{\text{HH}} = 15.1$ Hz, $^3\text{J}_{\text{HH}} = 4.1$ Hz, $^3\text{J}_{\text{HH}} = 7.0$ Hz, 2H, PCH_2), 2.90 (q, $^3\text{J}_{\text{HH}} = 7.1$ Hz, 2H, NCH_2CH_3), 3.90 ($\text{ABCDXX}'\text{D}'\text{C}'\text{B}'\text{A}'$, $\text{N} = |^3\text{J}_{\text{HP}} + ^4\text{J}_{\text{HP}}| = 3.3$ Hz, $^2\text{J}_{\text{HH}} = 14.6$ Hz, $^3\text{J}_{\text{HH}} = 7.0$ Hz, $^3\text{J}_{\text{HH}} = 7.5$ Hz, 2H, NCH_2CH_2), 4.54 ($\text{ABCDXA}'\text{B}'\text{C}'\text{D}'\text{X}'$, $\text{N} = |^3\text{J}_{\text{HP}} + ^4\text{J}_{\text{HP}}| = 9.9$ Hz, $^2\text{J}_{\text{HH}} = 14.6$ Hz, $^3\text{J}_{\text{HH}} = 4.1$ Hz, $^3\text{J}_{\text{HH}} = 8.0$ Hz, 2H, NCH_2CH_2).

3.2.7 [(PNP)Re(NBn)Cl]OTf (16c-OTf)

AgOTf (8.2 mg, 31.9 μ mol, 1.6 eq) is dissolved in Et₂O and cooled to -34°C before benzylbromide (ex.) is added. Immediate formation of a yellow precipitate indicates conversion to benzyl triflate. DTBMP (8.5 mg, 41.4 μ mol, 2 eq) is added to the cold suspension and the mixture stirred for 5 min. The cold reaction is filtered to **9** (12.5 mg, 21 μ mol, 1 eq) and stirred at room temperature for 15 h. The green precipitate is filtered off, washed with Et₂O until colourless, extracted with THF, overlaid with Et₂O and crystallized at -34°C. The product is filtered off and dried *in vac.* to give **16c-OTf** as a green microcrystalline solid. Yield: 10.5 mg, 12.6 μ mol, 60%.

Spectroscopic Characterization

¹H NMR (300 MHz, C₆D₆, [ppm]): δ = 1.00 (A₉XX'A', N = |³J_{HP} + ⁵J_{HP}| = 7.0 Hz, 18H, PC(CH₃)₃), 1.08 (A₉XX'A', N = |³J_{HP} + ⁵J_{HP}| = 7.2 Hz, 18H, PC(CH₃)₃), 2.02 (m, 2H, PCH₂), 2.28 (m, 2H, PCH₂), 3.80 (m, 2H, NCH₂CH₂), 4.61 (s, 2H, NCH₂Ph), 4.70 (m, 2H, NCH₂CH₂), 7.00 (t, ³J_{HH} = 7.4 Hz, 1H, NCH₂Ph), 7.13 (m, 2H, NCH₂Ph, partially superimposed), 7.49 (d, ³J_{HH} = 7.2 Hz, 2H, NCH₂Ph).

3.3.2 [(PNP)Re(NCHCH₃)Cl] (18b)

Published procedure

EtOTf (23 μL , 177 μmol , 1.05 eq) is added to a solution of **9** (100 mg, 168 μmol , 1 eq) in benzene (5-10 mL). The mixture is stirred at room temperature for 24 h. The solvent and residual EtOTf are removed by evaporation under reduced pressure and the residue is redissolved in benzene (5-10 mL). After deprotonation with KBTSA (33.5 mg, 168 μmol , 1 eq) and stirring for 2 h at room temperature the reaction mixture is filtered and the solvent removed *i. vac.* Extraction with pentane (4 x 3-5 mL), filtration and solvent evaporation gives a crude product with spectroscopic purity >95% and small amounts of parent **9** which is sufficient for most purposes. Full conversion is achieved by treatment of the crude product with additional EtOTf and work-up as described above. After final lyophilization from benzene analytically pure, red-brown **18b** is obtained (84.4 mg, 135 μmol , 81%). Spectroscopic Characterization reveals the formation of two stereoisomers in about 60:40 ratio. The ^{15}N -enriched sample was synthesized starting from **9**, prepared with 1- ^{15}N -azide.

Improved synthesis

Synthesis of the imido complex **16b-OTf** is carried out as described earlier. After reaction with EtOTf, the solvent is reduced to 2-5 mL and layered with diethylether (10 mL). Crystallization leads to pure compound **16b-OTf** which can be filtered off and used for deprotonation with KBTSA to yield pure **18b**.

Spectroscopic Characterization

^1H NMR (300 MHz, C_6D_6 , [ppm]): $\delta = 1.25$ ($\text{A}_9\text{XX}'\text{A}'_9$, $N = |^3J_{\text{HP}} + ^5J_{\text{HP}}| = 6.2 \text{ Hz}$, 18H, $\text{PC}(\text{CH}_3)_3$ isomer 2), 1.28 (m, 36H, $\text{PC}(\text{CH}_3)_3$ isomer 1), 1.34 ($\text{A}_9\text{XX}'\text{A}'_9$, $N = |^3J_{\text{HP}} + ^5J_{\text{HP}}| = 6.0 \text{ Hz}$, 18H, $\text{PC}(\text{CH}_3)_3$ isomer 2), 1.52 (m, 2H, PCH_2CH_2 isomer 1), 1.62 (m, 2H, PCH_2CH_2 isomer 2), 1.80 (m, 2H,

3.3.6 (PNP)Re(NCH₂)(CH₃) (25)

16a-OTf (50.0 mg, 65.7 μmol , 1 eq) is dissolved in THF (10 mL) and MeMgCl (44 μL , 3M in THF, 132 μmol , 2.0 eq) is added. The mixture is stirred at room temperature for 18 h before the solvent is evaporated and the residue extracted with pentanes (5 x 10 mL). After evaporation of the solvent, the residue is again extracted with pentanes (3 x 5 mL) and lyophilized out of benzene. Yield: 31.2 mg, 52.9 μmol , 81%.

Spectroscopic Characterization

^1H NMR (300 MHz, d_8 -THF, [ppm]): δ = 1.22 ($\text{A}_9\text{XX}'\text{A}'_9$, $\text{N} = |^3J_{\text{HP}} + ^5J_{\text{HP}}| = 5.8$ Hz, 18H, $\text{PC}(\text{CH}_3)_3$), 1.33 ($\text{A}_9\text{XX}'\text{A}'_9$, $\text{N} = |^3J_{\text{HP}} + ^5J_{\text{HP}}| = 5.8$ Hz, 18H,

suspension is filtered, the solvent evaporated and the residue dissolved in C₆D₆. NMR spectra show the formation of **26a** in 95% spectroscopic yield.

For **26b** the reaction is carried out similarly with a spectroscopic yield of 60%.

Via double deprotonation of 16 under H₂ atmosphere:

C₆H₆ (0.5 mL) is added to **16b-OTf** (5.4 mg, 7.0 μmol, 1 eq) and KO^tBu (2.0 mg, 17.8 μmol, 2.5 eq) and the atmosphere is exchanged for H₂ (1.5 bar). The mixture is heated to 70°C for 15 h and stirred at room temperature for another 3 d. ³¹P-NMR spectra show clean formation of **26b**.

Via Hydrogenation of 25:

25a (5.0 mg, 8.5 μmol) is dissolved in d₈-THF, degassed and pressurized with H₂ (1 bar). After heating to 70°C for 15 h, complete conversion of **26a** is observed in the NMR spectra, together with the formation of methane (¹H-NMR: 0.18 ppm).

For **26b** the reaction is carried out similarly.

Spectroscopic Characterization of 26a:

¹H NMR (300 MHz, C₆D₆, [ppm]): δ = -3.81 (t, ²J_{HP} = 11.6 Hz, 1H, ReH), 1.29 (A₉XX'A'₉, N = |³J_{HP} + ⁵J_{HP}| = 6.0 Hz, 18H, PC(CH₃)₃), 1.36 (A₉XX'A'₉, N = |³J_{HP} + ⁵J_{HP}| = 6.1 Hz, 18H, PC(CH₃)₃), 1.76 (m, 4H, PCH₂), 2.12 (dt, ⁴J_{HP} = 2.5 Hz, ²J_{HH} = 4.7 Hz, 1H, N=CH₂), 2.96 (m, 2H, NCH₂CH₂), 3.17 (m, 2H, NCH₂CH₂), 3.38 (dt, ⁴J_{HP} = 2.4 Hz, ²J_{HH} = 4.6 Hz, 1H, N=CH₂).

Spectroscopic Characterization of 26b:

¹H NMR (300 MHz, C₆D₆, [ppm]): δ = -4.25 (t, ²J_{HP} = 12.0 Hz, 1H, ReH, isomer 1), -3.91 (t, ²J_{HP} = 11.7 Hz, 1H, ReH, isomer 2), 1.24 (A₉XX'A'₉, N = |³J_{HP} + ⁵J_{HP}| = 5.9 Hz, 18H, PC(CH₃)₃, isomer 2), 1.31 (A₉XX'A'₉, N = |³J_{HP} + ⁵J_{HP}|

= 5.7 Hz, 18H, PC(CH₃)₃, isomer 1), 1.35 (m, PC(CH₃)₃, isomer 1, superimposed), 1.36 (A₉XX'A'₉, N = |³J_{HP} + ⁵J_{HP}| = 6.1 Hz, 18H, PC(CH₃)₃, isomer 2), 1.76 (m, 4H, PCH₂, isomer 1+2), 2.23 (qt, ⁴J_{HP} = 2.7 Hz, ³J_{HH} = 5.0 Hz, 1H, N=CHCH₃ isomer 2), 2.83 (dt, ³J_{HH} = 5.0 Hz, ⁵J_{HP} = 1.1 Hz, 3H, N=CHCH₃ isomer 2), 2.90 (dt, ³J_{HH} = 5.3 Hz, ⁵J_{HP} = 1.0 Hz, 3H, N=CHCH₃ isomer 1), 3.00 (m, 2H, NCH₂CH₂, isomer 1+2), 3.21 (m, 2H, NCH₂CH₂, isomer 1+2), 3.44 (m, ³J_{HH} = 5.3 Hz, 1H, N=CHCH₃, isomer 1).

³¹P{¹H} NMR (121.5 MHz, C₆D₆, [ppm]): δ = 79.3 (s, P^tBu₂, isomer 2), 75.0 (s, P^tBu₂, isomer 1).

3.3.9 Reaction of 16a with H₂ to 27a

27a-OTf:

16a-OTf (5.0 mg, 6.6 μmol, 1 eq) and MeOTf (cat.) are dissolved in C₆D₆, before the atmosphere is exchanged for H₂ gas (1 bar). Without MeOTf no reaction is observed. The mixture is heated to 80°C for 3 d to give clean conversion to **27a-OTf**. The solvent is evaporated and the residue washed with pentanes.

Spectroscopic Characterization

¹H NMR (300 MHz, C₆D₆, [ppm]): δ = 1.13 (s, 3H, NCH₃), 1.22 (A₉XX'A'₉, N = |³J_{HP} + ⁵J_{HP}| = 6.8 Hz, 18H, PC(CH₃)₃), 1.35 (A₉XX'A'₉, N = |³J_{HP} + ⁵J_{HP}| = 6.8 Hz, 18H, PC(CH₃)₃), 1.63 (m, 2H, PCH₂), 2.32 (m, 4H, PCH₂, NCH₂, superimposed), 3.08 (m, 2H, NCH₂, partially superimposed), 3.16 (t, ReH, partial superimposed), 4.76 (br, 1H, HPNP).

³¹P{¹H} NMR (121.5 MHz, C₆D₆, [ppm]): δ = 66.7 (s, P^tBu₂).

27a-Cl:

16a-Cl, prepared *in situ* from **18a** and HCl (2 M in Et₂O), is dissolved in THF and heated to 65°C under an atmosphere of H₂ (1 bar) for 18 h. The solvent is evaporated and the residue washed with pentanes and benzene. The spectroscopically pure blue residue **27a-Cl** is dried *in vac.* and dissolved in CD₂Cl₂.

Spectroscopic Characterization

¹H NMR (300 MHz, CD₂Cl₂, [ppm]): δ = 1.53 (A₉XX'A'₉, N = |³J_{HP} + ⁵J_{HP}| = 6.9 Hz, 18H, PC(CH₃)₃), 1.65 (A₉XX'A'₉, N = |³J_{HP} + ⁵J_{HP}| = 6.9 Hz, 18H,

PC(CH₃)₃, 2.10 (s, 3H, NCH₃), 2.21 (m, 2H, PCH₂), 2.47 (m, 4H, PCH₂, NCH₂, superimposed), 3.03 (m, 2H, NCH₂), 3.57 (t, ²J_{HP} = 18.2 Hz, 1H, ReH).

³¹P{¹H} NMR (121.5 MHz, CD₂Cl₂, [ppm]): δ = 67.6 (s, P^tBu₂).

3.3.10 Hydrogenation of 28

Freshly prepared **28b** (ca. 7 μmol) in CD₂Cl₂ solution (0.5 mL), still containing traces of acid, is pressurized with H₂ (1.5 bar). The color of the solution changes within 5-10 min from green to rose. ³¹P-NMR spectra display conversion into a single compound in 93% yield. ¹H-NMR spectra are due to residual solvent and signal overlap not significant. No signals below 0 ppm in the ¹H-NMR spectra are detected.

³¹P{¹H} NMR (121.5 MHz, CD₂Cl₂, [ppm]): δ = 77.8 (s, P^tBu₂).

3.4 Reactivity of ketimido complexes

3.4.1 Protonation to imido complexes (16 and 28)

Azavinylidene complexes **18** and **26** can be quantitatively (spectroscopically) protonated back to the respective imido complexes by dissolving the complex in benzene, Et₂O or DCM and adding 1 eq of acid (HOTf, HBAr^F₄ or NH₄PF₆). Excess of a strong acid leads to degradation of the complexes.

Spectroscopic Characterization for 28b-BAr^F₄

¹H NMR (300 MHz, CD₂Cl₂, [ppm]): δ = -6.18 (t, ²J_{HP} = 14.3 Hz, 1H, ReH), 1.28 (t, ³J_{HH} = 7.1 Hz, 3H, NCH₂CH₃), 1.42 (m, 36H, PC(CH₃)₃), 2.34 (m, 4H, PCH₂), 2.52 (m, 2H, NCH₂CH₃), 3.15 (m, 2H, NCH₂), 3.39 (m, 2H, NCH₂), 7.57 (s, 4H, BAr^F₄), 7.73 (s, 8H, BAr^F₄).

³¹P{¹H} NMR (121.5 MHz, CD₂Cl₂, [ppm]): δ = 96.5 (s, P^tBu₂).

3.4.2 Release of NCMe upon treatment with isonitriles (Synthesis of 20)

CN^tBu (2.5 μ L, 24 μ mol, 3 eq) is added to a solution of **18b** (5.0 mg, 8.0 μ mol, 1 eq) in C₆D₆ (0.5 mL) and the mixture is stirred for 10 d at room temperature. Heating (2 d, 60°C) leads to partial degradation. Spectroscopic yield to **20** is about 85% based on NMR spectra. The solvent is evaporated and the green residue washed with pentanes until colorless and dried *in vacuo*.

3.4.3 Release of NCMe upon deprotonation of 18b (Synthesis of 19)

18b (30.0 mg, 48.1 μ mol, 1 eq), KBTSA (9.6 mg, 48.1 μ mol, 1 eq) and CN^tBu (11 μ L, 105 μ mol, 2.2 eq) are dissolved in THF (5 mL) at room temperature. The solution immediately turns bright orange and the ¹H-NMR spectrum shows clean formation of **19** under release of acetonitrile. After evaporation of the solvent under reduced pressure, the product is extracted with pentanes and the solvent removed *in vacuo*. Lyophilization from benzene yields the **19** as orange powder (33.0 mg, 46.3 μ mol, 96%).

Spectroscopic Characterization

¹H NMR (400 MHz, C₆D₆, [ppm]): δ = 1.42 (A₁₈XX'A'₁₈ = N = |³J_{HP} + ⁵J_{HP}| = 5.9 Hz, 36H, PC(CH₃)₃), 1.43 (s, 18H, CNC(CH₃)₃), 1.96 (A₂B₂XX'B'₂A'₂, N = |²J_{HP} + ⁴J_{HP}| = 3.4 Hz, ³J_{HH} = 6.5 Hz, 4H, PCH₂), 3.26 (A₂B₂XX'B'₂A'₂, N = |³J_{HP} + ⁴J_{HP}| = 6.5 Hz, ³J_{HH} = 6.5 Hz, 4H, NCH₂).

¹³C{¹H} NMR (100.6 MHz, C₆D₆, [ppm]): δ = 28.0 (AXX'A', N = |¹J_{CP} + ³J_{CP}| = 7.9 Hz, PCH₂), 30.9 (A₆XX'A'₆, N = |²J_{CP} + ⁴J_{CP}| = 2.6 Hz, PC(CH₃)₃), 33.4 (s, NC(CH₃)₃), 37.5 (A₂XX'A'₂, N = |¹J_{CP} + ³J_{CP}| = 8.1 Hz, PC(CH₃)₃), 54.8 (s, NC(CH₃)₃), 67.2 (AXX'A', N = |²J_{CP} + ³J_{CP}| = 7.1 Hz, NCH₂), 194.8 (t, ²J_{CP} = 5.1 Hz, CNC(CH₃)₃).

³¹P{¹H} NMR (162.0 MHz, C₆D₆, [ppm]): δ = 90.2 (s, P^tBu₂).

IR (KBr, cm⁻¹): 1975 (m, ν (C \equiv N)), 1957 (m, ν (C \equiv N)), 1797 (s, ν (C \equiv N)), 1769 (s, ν (C \equiv N)).

IR (liq.) (DCM, cm⁻¹): 1974 (br, ν (C \equiv N)), 1955 (br, ν (C \equiv N)), 1778 (s, ν (C \equiv N)), 1742 (s, ν (C \equiv N)).

3.4.4 Oxidation of 18a or 25a with Ag⁺ (Synthesis of 24)

25a (3.8 mg, 6.5 μ mol, 1 eq) is dissolved in C_6D_6 and AgOTf (1.7 mg, 6.5 μ mol, 1 eq) is added. The solution turns dark immediately and Ag precipitates. After stirring for 1h, the mixture is filtered, the residue washed with benzene and THF and extracted with DCM. After crystallization out of DCM/pentane, pure **24** is obtained according to NMR data. The reaction can be carried out similarly using **18a**, however the spectroscopic product was not obtained pure (78% spectroscopic yield).

3.4.5 Oxidation of 18a with [CPh₃][PF₆] (Synthesis of 16d-PF₆)

18a (5.0 mg, 8.2 μ mol, 1 eq) is dissolved in C_6D_6 and [CPh₃][PF₆] (3.2 mg, 8.2 μ mol, 1 eq) is added. The color of the solution immediately turns deep red. The solvent is evaporated and the residue washed with pentanes. After drying i. vac., the residual is dissolved in d_8 -THF to observe formation of **16a-PF₆** and **16d-PF₆** in an about equimolar ratio.

Spectroscopic Characterization for 16d-PF₆

¹H NMR (300 MHz, d_8 -THF, [ppm]): δ = 1.01 ($A_{18}XX'A'_{18} = N = |^3J_{HP} + ^5J_{HP}| = 7.3$ Hz, 36H, PC(CH₃)₃), 1.23 ($A_{18}XX'A'_{18} = N = |^3J_{HP} + ^5J_{HP}| = 6.9$ Hz, 36H, PC(CH₃)₃), 2.3 (m, 2H, PCH₂), 2.4 (m, 2H, PCH₂), 4.1 (m, 2H, NCH₂), 4.3 (m, 2H, NCH₂), 4.52 (s, 2H, NCH₂CPh₃), 7.2 (m, 15H, CPh₃).

³¹P{¹H} NMR (121.5 MHz, d_8 -THF, [ppm]): δ = 87.6 (s, P^tBu₂).

Addition of KBTSA (1.0 mg, 8.2 μ mol, 1 eq) yields a mixture of **18a** and **18d** in a clean reaction.

³¹P{¹H} NMR of **18d** (121.5 MHz, d_8 -THF, [ppm]): δ = 45.9 (s, P^tBu₂).

³¹P{¹H} NMR of **18d** (121.5 MHz, C_6D_6 , [ppm]): δ = 44.9 (s, P^tBu₂), 41.9 (s, P^tBu₂).

3.4.6 Oxidation of **18b** with Ag⁺

CD₂Cl₂ (0.5 mL) is trap-to-trap transferred to a J-Young NMR tube charged with **18b** (5.0 mg, 8.0 μmol, 1 eq) and AgPF₆ (2.0 mg, 8.0 μmol, 1 eq). The mixture is warmed to -70°C and shaken for 10 min. The ³¹P and ¹H NMR spectra at room temperature show the complete consumption of **18b** and formation of a paramagnetic compound ($\delta_{\text{H}}(300 \text{ MHz, ppm}) = 23.1 \text{ (br)}, 7.1 \text{ (br)}, 6.8 \text{ (br)}, 0.0 \text{ (br)}, -3.6 \text{ (br)}, -31.7 \text{ (br)}$), which slowly decomposes at room temperature to a mixture of diamagnetic compounds that was not further characterized.

3.4.7 [(PNP)Re(NCHCH₂)Cl]OTf (**22**)

18b (5.0 mg, 8.0 μmol, 1 eq) and AgOTf (2.1 mg, 8.0 μmol, 1 eq) are dissolved in d₂-DCM at -34°C. The color of the reaction immediately turns deep red and a grey precipitate is formed. 2,4,6-Tri-*tert*-butyl phenoxy radical (2.6 mg, 9.9 μmol, 1.2 eq) is added to the cold suspension and the reaction is allowed to warm to room temperature. After filtration, the product is precipitated by pentane addition (2 mL), filtered off and dried *in vacuo* as a greenish black solid.

Spectroscopic Characterization

¹H NMR (300 MHz, C₆D₆, [ppm]): $\delta = 1.02$ (A₉XX'A', N = $|^3J_{\text{HP}} + ^5J_{\text{HP}}| = 6.9 \text{ Hz}$, 18H, PC(CH₃)₃), 1.16 (A₉XX'A', N = $|^3J_{\text{HP}} + ^5J_{\text{HP}}| = 7.2 \text{ Hz}$, 18H, PC(CH₃)₃), 2.12 (ABCDXX'D'C'B'A', N = $|^2J_{\text{HP}} + ^4J_{\text{HP}}| = 2.8 \text{ Hz}$, $^2J_{\text{HH}} = 14.9 \text{ Hz}$, $^3J_{\text{HH}} = 6.4 \text{ Hz}$, $^3J_{\text{HH}} = 3.0 \text{ Hz}$, 2H, PCH₂), 2.30 (ABCDXX'D'C'B'A', N = $|^2J_{\text{HP}} + ^4J_{\text{HP}}| = 3.8 \text{ Hz}$, $^2J_{\text{HH}} = 14.9 \text{ Hz}$, $^3J_{\text{HH}} = 8.5 \text{ Hz}$, $^3J_{\text{HH}} = 8.7 \text{ Hz}$, 2H, PCH₂), 3.66 (ABCDXX'D'C'B'A', N = $|^3J_{\text{HP}} + ^4J_{\text{HP}}| = 2.4 \text{ Hz}$, $^2J_{\text{HH}} = 14.8 \text{ Hz}$, $^3J_{\text{HH}} = 8.7 \text{ Hz}$, $^3J_{\text{HH}} = 6.4 \text{ Hz}$, 2H, NCH₂CH₂), 4.87 (ABCDXX'D'C'B'A', N = $|^3J_{\text{HP}} + ^4J_{\text{HP}}| = 12.2 \text{ Hz}$, $^2J_{\text{HH}} = 14.8 \text{ Hz}$, $^3J_{\text{HH}} = 3.0 \text{ Hz}$, $^3J_{\text{HH}} = 8.5 \text{ Hz}$, 2H, NCH₂CH₂), 5.08 (d, $^3J_{\text{HH}} = 8.0 \text{ Hz}$, 1H, ReNCHCH₂), 5.23 (d, $^3J_{\text{HH}} = 15.3 \text{ Hz}$, 1H, ReNCHCH₂), 7.08 (dd, $^3J_{\text{HH}} = 15.3 \text{ Hz}$, $^3J_{\text{HH}} = 8.0 \text{ Hz}$, 1H, ReNCHCH₂).

³¹P{¹H} NMR (121.5 MHz, C₆D₆, [ppm]): $\delta = 89.2$ (s, P^tBu₂).

Mass Spectrometry

LIFDI+ (toluene, m/z⁺): 623.1 (C₂₂H₄₇ClN₂P₂Re⁺).

3.4.8 Release of NCMe from **22** (Synthesis of [(PNP)ReCl₂] (**3**))

22 (5.0 mg, 6.5 μ mol, 1 eq), 12-crown-4 (3.1 μ L, 20 μ mol, 3 eq), LiCl (2.8 mg, 65 μ mol, 10 eq), DBU (0.5 μ L, 3.5 μ mol, 0.5 eq) and naphthalene (0.8 mg, 6.5 μ mol, 1 eq) as internal standard are dissolved in d₈-THF in a J-Young-NMR tube and shaken for 12 h. ¹H and ³¹P NMR spectra show the formation of **3** and acetonitrile in about 30% yield.

3.4.9 Release of NCMe from **18b** with CuCl₂ and base

18b (5.0 mg, 8.0 μ mol, 1 eq), CuCl₂ (1.1 mg, 8.0 μ mol, 1 eq) and DBU (1.2 μ L, 8.0 μ mol, 1 eq) are suspended in d₈-THF at -34°C and stirred for 2 d at room temperature before another equivalent of CuCl₂ and DBU are added. The ³¹P NMR spectrum shows the formation of **3** in about 25% yield.

3.4.10 Oxidation of **18b** with N-chlorosuccinimide (Synthesis of **23**)

A mixture of **18b** (20.0 mg, 32.0 μ mol, 1 eq) and N-chlorosuccinimide (8.6 mg, 64.0 μ mol, 2 eq) is dissolved in benzene (5 mL) and stirred at room temperature for 18 h. The formation of acetonitrile is confirmed by ¹H (spectroscopic yield about 80%, hexamethylbenzene (1 eq) as internal standard), ¹⁵N and ¹H-¹⁵N-HMBC NMR spectroscopy. The mixture is worked up by evaporation of the solvent under reduced pressure, washing with pentane (2 x 5 mL) and extraction with benzene (2 x 3 mL). After filtration and solvent evaporation residual succinimide is sublimed off over 18 h (80°C @ 10 mTorr) to obtain **23** as a green powder (19.5 mg, 29.9 μ mol, 93%), which was identified by comparison of ¹H NMR, UV-vis and LIFDI-MS data with an original sample.

3.4.11 Oxidation of **18a** with NCS

18a (5.0 mg, 8.1 μ mol, 1 eq) and NCS (2.2 mg, 16.4 μ mol, 2 eq) are dissolved in C₆D₆. Formation of four diamagnetic signals in the ³¹P-NMR spectra is observed, besides the signal corresponding to **23** in the ¹H-NMR spectrum.

^1H NMR (300 MHz, C_6D_6 , [ppm]): $\delta = 10.8$ (s, **23**).

$^{31}\text{P}\{^1\text{H}\}$ NMR (121.5 MHz, C_6D_6 , [ppm]): $\delta = 91.4$ (s, 65%), 71.1 (s, 29%), 47.7 (s, 1%), 42.8 (s, 5%).

LIFDI+(toluene, m/z⁺): 682.5 (unknown); 652.1 (unknown); 596.2 (**23**⁺).

IR (KBr, cm^{-1}): 2258 (w, $\nu(\text{C}\equiv\text{N})$), 2223 (w, $\nu(\text{C}\equiv\text{N})$).

3.4.12 [(PNP)ReCl₃] (**23**)

N-chlorosuccinimide (8.6 mg, 64.8 μmol , 1 eq) is added to a frozen solution of **3** (40.0 mg, 64.8 μmol , 1 eq) in benzene (5-10 mL) and warmed to room temperature. Upon melting the color changes from violet to dark green. After stirring for 2 h, the volume is reduced to about 3 mL and the product is precipitated with pentanes (10 mL). After filtration, the green powder is washed with pentanes (2 x 5 mL), dissolved in benzene (3 x 5 mL), filtered and lyophilized. The crude product is heated to 80°C (30 mTorr) for 18 h to sublime off residual succinimide. Yield: 32.0 mg, 49.0 μmol , 76%.

Spectroscopic Characterization

^1H NMR (300 MHz, d_8 -THF, [ppm]): $\delta = -15.8$ (br), 10.7 (br).

Magnetic Properties

Evans method $\mu_{\text{eff}}^{298\text{K}}$: 1.54 μB .

Elemental Analysis

|---|---------|----------------------------|
| $\text{C}_{20}\text{H}_{44}\text{Cl}_3\text{NP}_2\text{Re}$ (%) | calcd.: | C, 36.78; H, 6.79; N, 2.14 |
| | found: | C, 37.26; H, 7.22; N, 2.51 |

Mass Spectrometry

LIFDI+ (toluene, m/z⁺): 652.2 ($\text{C}_{20}\text{H}_{44}\text{Cl}_3\text{NP}_2\text{Re}^+$).

3.4.13 Reduction of **23** (Synthesis of [(PNP)ReCl₂] (**3**))

23 (5.0 mg, 7.7 μmol, 1 eq) and CoCp₂* (2.5 mg, 7.7 μmol, 1 eq) are dissolved in d₈-THF (0.5 mL) in a J-Young NMR tube. Upon shaking the color of the solution turns from green to red-brown and a yellow precipitate is formed. Examination by ¹H and ³¹P NMR spectroscopy reveals clean formation of **3**.

3.4.14 Reduction of **23** under N₂ (Synthesis of [(PNP)Re(N)Cl] (**9**))

Na/Hg (209 mg, 1 M, 15.4 μmol, 2 eq) is added to a solution of **23** (5.0 mg, 7.7 μmol, 1 eq) in d₈-THF (0.5 mL) at room temperature and stirred under N₂ atmosphere for 15 h. Examination by ¹H and ³¹P NMR spectroscopy reveals formation of **9** in about 70% spectroscopic yield.

3.4.15 Hydrogenation of **18**

In the presence of HCl

To **18a** (5.0 mg, 8.1 μmol, 1 eq) a solution of HCl (8 μL, 2 M in Et₂O, 1 eq) in THF is added and the reaction mixture is pressurized with H₂ (1 bar). The solution is heated to 65°C for 18 h to observe formation of **27** in 70% spectroscopic yield.

In the presence of KO^tBu

18b (4.4 mg, 7.0 μmol, 1 eq) and KO^tBu (0.8 mg, 7.0 μmol, 1 eq) are suspended in benzene (0.5 mL) and pressurized with H₂ (1.5 bar). The mixture is heated to 70°C for 2 d and then stirred for 2 d at room temperature to observe conversion to **26b** in 95% spectroscopic yield.

2 List of abbreviations

| | |
|----------------------------------|---|
| $\{\text{MNNM}\}^{x\pi y\delta}$ | x = number of electrons in π -symmetric orbitals; y = number of electrons in δ -symmetric orbitals of a $\{\text{MNNM}\}$ unit |
| δ | chemical shift [ppm] |
| ν | wave number [cm^{-1}] |
| μ_{eff} | effective magnetization |
| atm | standard atmosphere |
| BAr^{F_4} | $[\text{B}\{\text{C}_6\text{H}_3(\text{CF}_3)_2\}_4]^-$ |
| BDE | bond dissociation energy |
| br | broad |
| ^tBu | <i>tert</i> -butyl |
| Bn | benzyl |
| calcd. | calculated |
| Cp | cyclopentadienyl |
| Cp^* | (penta-methyl)cyclopentadienyl |
| CV | cyclic voltammetry |
| d | doublet |
| DCM | dichloromethane |
| DFT | density functional theory |
| Et | ethyl |
| equiv. | equivalents |
| ESI | electron spray ionization |
| exp | experimental |
| Fc | ferrocene |
| Fc^+ | ferrocenium cation |
| FT | fourier transform |
| h | hour |
| hpp | hexahydropyrimidinopyrimidine (deprotonated TBD) |
| HOMO | highest occupied molecular orbital |

| | |
|---------------------------|---|
| <i>i</i> Pr | <i>iso</i> -propyl |
| IR | infrared |
| <i>i. vac.</i> | in vacuo |
| LUMO | lowest unoccupied molecular orbital |
| m | multiplet (NMR) or medium (IR) |
| Me | methyl |
| MO | molecular orbital |
| <i>M</i> | molar |
| NMR | nuclear magnetic resonance |
| OTf | trifluoromethanesulfonate |
| Ph | phenyl |
| PhO· | 2,4,6-tri- <i>tert</i> -butylphenoxy radical |
| PNP | bis(di- <i>tert</i> -butylphosphinoethylene)amide |
| ^H PNP | bis(di- <i>tert</i> -butylphosphinoethylene)amine |
| P=N=P | bis(di- <i>tert</i> -butylphosphinoethylidene)amide |
| PNP ^{<i>i</i>Pr} | bis(di- <i>iso</i> -propylphosphinoethylene)amide |
| ppm | parts per million |
| q | quartet |
| RT | room temperature |
| S | spin |
| t | triplet |
| TBD | 1,3,5-Triazabicyclo[4.4.0]dec-5-ene, Hhpp |
| THF | tetrahydrofuran |
| TIP | temperature independent paramagnetism |
| vs | versus |
| w | weak |

3 Crystallographic details

3.1 [(PNP)ReCl₂] (3)

| | |
|-------------------------------------|--|
| Empirical formula | C ₂₀ H ₄₄ Cl ₂ NP ₂ Re |
| Formula weight | 617.60 |
| Temperature | 100(2) K |
| Wavelength | 0.56086 Å |
| Crystal system, space group | Orthorhombic, P2 ₁ 2 ₁ 2 ₁ |
| Unit cell dimensions | a = 12.1991(13) Å α = 90° b = 12.3901(14) Å β = 90° c = 16.5297(18) Å γ = 90° |
| Volume | 2498.4(5) Å ³ |
| Z, Density (calculated) | 4, 1.642 Mg/m ³ |
| Absorption coefficient | 2.799 mm ⁻¹ |
| F(000) | 1240 |
| Crystal shape and color | Block, blue |
| Crystal size | 0.407 x 0.217 x 0.188 mm ³ |
| θ range for data collection | 1.297 to 23.674° |
| Index ranges | -17 ≤ h ≤ 17, -17 ≤ k ≤ 17, -23 ≤ l ≤ 23 |
| Reflections collected / independent | 36601 / 7624 [R(int) = 0.0539] |
| Completeness to θ = 19.665° | 99.4 % |
| Absorption correction | Numerical |
| Max. and min. transmission | 0.7295 and 0.5455 |
| Refinement method | Full-matrix least-squares on F ² |
| Data / restraints / parameters | 7624 / 240 / 250 |
| Goodness-of-fit on F ² | 1.137 |
| Final R indices [I > 2σ(I)] | R1 = 0.0380, wR2 = 0.0935 |
| R indices (all data) | R1 = 0.0405, wR2 = 0.0966 |
| Largest diff. peak and hole | 4.211 and -2.383 eÅ ⁻³ |

3.2 [(PNP)Re(NCMe)Cl₂]

| | | |
|-------------------------------------|--|-----------------|
| Empirical formula | C ₂₂ H ₄₇ Cl ₂ N ₂ P ₂ Re | |
| Formula weight | 658.65 | |
| Temperature | 298(2) K | |
| Wavelength | 0.71073 Å | |
| Crystal system, space group | Triclinic, P-1 | |
| Unit cell dimensions | a = 7.4049(3) Å | α = 93.800(2)° |
| | b = 12.4480(5) Å | β = 101.613(2)° |
| | c = 15.8353(7) Å | γ = 105.263(2)° |
| Volume | 1368.30(10) Å ³ | |
| Z, Density (calculated) | 2, 1.599 Mg/m ³ | |
| Absorption coefficient | 4.765 mm ⁻¹ | |
| F(000) | 664 | |
| Crystal shape and color | Plate, clear intense green | |
| Crystal size | 0.109 x 0.073 x 0.053 mm ³ | |
| θ range for data collection | 2.290 to 30.659° | |
| Index ranges | -10 ≤ h ≤ 10, -17 ≤ k ≤ 17, -22 ≤ l ≤ 22 | |
| Reflections collected / independent | 70775 / 8447 [R(int) = 0.0732] | |
| Completeness to θ = 25.242° | 99.9% | |
| Refinement method | Full-matrix least-squares on F ² | |
| Data / restraints / parameters | 8447 / 0 / 275 | |
| Goodness-of-fit on F ² | 1.048 | |
| Final R indices [I > 2σ(I)] | R1 = 0.0313, wR2 = 0.0432 | |
| R indices (all data) | R1 = 0.0485, wR2 = 0.0462 | |
| Largest diff. peak and hole | 0.597 and -0.748 eÅ ⁻³ | |

3.3 [(PNPⁱPr)Re(hpp)Cl] (5)

| | | |
|-------------------------------------|--|------------------|
| Empirical formula | C ₂₃ H ₄₈ ClN ₄ P ₂ Re | |
| Formula weight | 664.24 | |
| Temperature | 100(2) K | |
| Wavelength | 0.56086 Å | |
| Crystal system, space group | Triclinic, P-1 | |
| Unit cell dimensions | a = 7.9189(3) Å | α = 85.3520(10)° |
| | b = 9.5438(4) Å | β = 83.0080(10)° |
| | c = 18.8217(7) Å | γ = 76.5260(10)° |
| Volume | 1370.99(9) Å ³ | |
| Z, Density (calculated) | 2, 1.609 Mg/m ³ | |
| Absorption coefficient | 2.509 mm ⁻¹ | |
| F(000) | 672 | |
| Crystal shape and color | Block, green | |
| Crystal size | 0.184 x 0.155 x 0.150 mm ³ | |
| θ range for data collection | 0.861 to 22.198° | |
| Index ranges | -10 ≤ h ≤ 10, -12 ≤ k ≤ 12, -25 ≤ l ≤ 25 | |
| Reflections collected / independent | 91475 / 7000 [R(int) = 0.0442] | |
| Completeness to θ = 19.665° | 100.0% | |
| Absorption correction | Semi-empirical from equivalents | |
| Max. and min. transmission | 0.462 and 0.3938 | |
| Refinement method | Full-matrix least-squares on F ² | |
| Data / restraints / parameters | 7000 / 60 / 468 | |
| Goodness-of-fit on F ² | 1.098 | |
| Final R indices [I > 2σ(I)] | R1 = 0.0164, wR2 = 0.0339 | |
| R indices (all data) | R1 = 0.0189, wR2 = 0.0347 | |
| Largest diff. peak and hole | 0.928 and -1.237 eÅ ⁻³ | |

3.4 [(^HPNP)Re(N)Cl][Cl] (12)

| | |
|-------------------------------------|---|
| Empirical formula | C ₂₀ H ₄₅ Cl ₂ N ₂ P ₂ Re |
| Formula weight | 632.62 |
| Temperature | 100(2) K |
| Wavelength | 0.56086 Å |
| Crystal system, space group | Orthorhombic, Pbc _a |
| Unit cell dimensions | a = 15.1843(12) Å α = 90° b = 12.3918(9) Å β = 90° c = 27.434(2) Å γ = 90° |
| Volume | 5162.0(7) Å ³ |
| Z, Density (calculated) | 8, 1.628 Mg/m ³ |
| Absorption coefficient | 2.711 mm ⁻¹ |
| F(000) | 2544 |
| Crystal shape and color | Plate, yellow |
| Crystal size | 0.092 x 0.064 x 0.058 mm ³ |
| θ range for data collection | 1.579 to 20.596° |
| Index ranges | -19 ≤ h ≤ 18, -15 ≤ k ≤ 15, -34 ≤ l ≤ 34 |
| Reflections collected / independent | 116371 / 5313 [R(int) = 0.1613] |
| Completeness to θ = 19.665° | 100.0% |
| Absorption correction | Numerical |
| Max. and min. transmission | 0.7445 and 0.6445 |
| Refinement method | Full-matrix least-squares on F ² |
| Data / restraints / parameters | 5313 / 0 / 260 |
| Goodness-of-fit on F ² | 1.050 |
| Final R indices [I > 2σ(I)] | R1 = 0.0329, wR2 = 0.0518 |
| R indices (all data) | R1 = 0.0604, wR2 = 0.0593 |
| Largest diff. peak and hole | 0.980 and -1.461 eÅ ⁻³ |

3.5 [(PNP)Re(N)(CH₃)] (13)

| | |
|-------------------------------------|--|
| Empirical formula | C ₂₁ H ₄₇ N ₂ P ₂ Re |
| Formula weight | 575.74 |
| Temperature | 100(2) K |
| Wavelength | 0.56086 Å |
| Crystal system, space group | Orthorhombic, Pbc _a |
| Unit cell dimensions | a = 11.9638(4) Å α = 90° b = 15.5451(5) Å β = 90° c = 26.4482(8) Å γ = 90° |
| Volume | 4918.8(3) Å ³ |
| Z, Density (calculated) | 8, 1.555 Mg/m ³ |
| Absorption coefficient | 2.736 mm ⁻¹ |
| F(000) | 2336 |
| Crystal shape and color | Plate, yellow |
| Crystal size | 0.207 x 0.190 x 0.078 mm ³ |
| θ range for data collection | 1.215 to 22.317° |
| Index ranges | -16 ≤ h ≤ 12, -20 ≤ k ≤ 21, -35 ≤ l ≤ 35 |
| Reflections collected / independent | 50947 / 6396 [R(int) = 0.0634] |
| Completeness to θ = 19.665° | 100.0% |
| Absorption correction | Numerical |
| Max. and min. transmission | 0.8532 and 0.6696 |
| Refinement method | Full-matrix least-squares on F ² |
| Data / restraints / parameters | 6396 / 0 / 248 |
| Goodness-of-fit on F ² | 1.173 |
| Final R indices [I > 2σ(I)] | R1 = 0.0412, wR2 = 0.0692 |

4 List of scientific contributions

Publications in scientific journals

1. M. G. Scheibel, I. Klopsch, H. Wolf, P. Stollberg, D. Stalke, S. Schneider, *Eur. J. Inorg. Chem.* **2013**, 3453-3457.
2. A. N. Marziale, A. Friedrich, I. Klopsch, M. Drees, V. R. Celinski, J. Schmedt auf der Günne, S. Schneider, *J. Am. Chem. Soc.* **2013**, *135*, 13342-13355.
3. I. Klopsch, M. Finger, C. Würtele, B. Milde, D. B. Werz, S. Schneider, *J. Am. Chem. Soc.* **2014**, *136*, 6881-6883.
4. I. Klopsch, M. Finger, C. Würtele, S. Schneider, *Angew. Chem. Int. Ed.* **2016**, *55*, 4786-4789.
5. I. Klopsch, S. Schneider, *Topics in Organometallic Chemistry*, in progress.

Oral contributions to conferences

1. I. Klopsch, M. Finger, C. Würtele, S. Schneider, "N₂-Splitting in the Coordination Sphere of Rhenium", 10th Coordination Chemistry Conference, Kaiserslautern/Germany, 2014.
2. I. Klopsch, M. G. Scheibel, M. Finger, C. Würtele, S. Schneider, "Electronic Structure-Reactivity Relationships for N₂ Fixation and NR Group Transfer", Catalytic Routines for Small Molecule Activation (CARISMA), COST Meeting, Venice/Italy, 2014.
3. I. Klopsch, M. Finger, C. Würtele, S. Schneider, "N₂-Splitting and Functionalization in the Coordination Sphere of Rhenium", 16th International Seminar of PhD Students on Organometallic and Coordination Chemistry, Lichtenfels/Germany, 2015.
4. I. Klopsch, M. Finger, C. Würtele, S. Schneider, "N₂-Splitting and Functionalization in the Coordination Sphere of Rhenium", Pacifichem, Honolulu/Hawaii/USA, 2015.

5. I. Klopsch, J. Abbenseth, M. Finger, C. Würtele, S. Schneider, "N₂-Splitting and Functionalization in the Coordination Sphere of Rhenium", Catalytic Routines for Small Molecule Activation (CARISMA), COST Meeting, Ljubljana/Slovenia, 2016.

Poster presentations on conferences

1. I. Klopsch, M. Finger, C. Würtele, S. Schneider, "N₂-Splitting in the Coordination Sphere of Rhenium", 17. Conference on Inorganic Chemistry of the Wöhler Foundation, Saarbrücken/Germany, 2014.
2. I. Klopsch, M. Finger, C. Würtele, S. Schneider, "N₂-Splitting in the Coordination Sphere of Rhenium", Lower Saxony Catalysis Symposium (NiKaS), Göttingen/Germany, 2014, awarded.
3. I. Klopsch, M. Finger, C. Würtele, S. Schneider, "N₂-Splitting in the Coordination Sphere of Rhenium", 11th Coordination Chemistry Conference, Paderborn/Germany, 2015.
4. I. Klopsch, M. Finger, C. Würtele, S. Schneider, "N₂-Splitting in the Coordination Sphere of Rhenium", 18. Norddeutsches Doktorandenkolloquium, Goslar/Germany, 2015.

5 Curriculum vitae

Personal data

Name: Isabel Klopsch
Date of birth: 26.12.1987
Place of birth: Erlangen, Germany
Citizenship: German
Adress: Friedrichstraße 1
37073 Göttingen
Germany

Education

1998-2007 Ohm-Gymnasium Erlangen
2004-2005 School year abroad in Deux-Montagnes, Québec, Canada
2007 School Graduation: Abitur
2007-2010 Studies Bachelor of Science in Chemistry
Friedrich-Alexander University Erlangen-Nürnberg
2010 Bachelor Degree in Chemistry
Thesis: "Photocatalytic Oxidation of Alcohols"
Advisor: Prof. Dr. Sven Rau
2010-2012 Studies Master of Science in Chemistry
Friedrich-Alexander University Erlangen-Nürnberg
2012 Master Degree in Chemistry
Thesis: "Modified activation concepts for the chromium-based
selective oligomerization of ethylene"
Advisor: Prof. Dr. Peter Wasserscheid

JAN 2013-
OCT 2016

PhD Thesis at the Georg August University Göttingen in the
group of Prof. Dr. Sven Schneider
Thesis: "N₂ Splitting and Functionalization in the coordination
sphere of rhenium"
