

# **N<sub>2</sub> Splitting and Functionalization in the Coordination Sphere of Tungsten**

## **Dissertation**

zur Erlangung des mathematisch-naturwissenschaftlichen Doktorgrades  
"Doctor rerum naturalium"  
der Georg-August-Universität Göttingen

im Promotionsprogramm der  
Georg-August University School of Science (GAUSS)

vorgelegt von:

**Bastian Schluschaß**

aus Frankfurt am Main

**Göttingen, 2020**

## Betreuungsausschuss

**Prof. Dr. Sven Schneider**

Institut für Anorganische Chemie, Georg-August-Universität Göttingen

**Prof. Dr. Franc Meyer**

Institut für Anorganische Chemie, Georg-August-Universität Göttingen

## Mitglieder der Prüfungskommission

Referent **Prof. Dr. Sven Schneider**  
Institut für Anorganische Chemie,  
Georg-August-Universität Göttingen

Korreferent **Prof. Dr. Franc Meyer**  
Institut für Anorganische Chemie,  
Georg-August-Universität Göttingen

## Weitere Mitglieder der Prüfungskommission

**Prof. Dr. Manuel Alcarazo**

Institut für Organische und Biomolekulare Chemie,  
Georg-August-Universität Göttingen

**Prof. Dr. Dirk Schwarzer**

Max-Planck-Institut für Biophysikalische Chemie, Göttingen

**Dr. Michael John**

Institut für Organische und Biomolekulare Chemie,  
Georg-August-Universität Göttingen

**Dr. Christian Sindlinger**

Institut für Anorganische Chemie,  
Georg-August-Universität Göttingen

Tag der mündlichen Prüfung: 22.09.2020

## Acknowledgements

First of all, I would like to express my appreciation to my supervisor **Prof. Dr. Sven Schneider** for providing me not only with this interesting and challenging topic, but also with scientific support, inspiring discussions, excellent laboratory conditions as well as the opportunity to present my work at several conferences.

Furthermore, I want to express my gratitude to **Prof. Dr. Franc Meyer** for taking the part of my second supervisor and being referee for my thesis.

Moreover, I wish to show my gratitude to the following people and institutions:

- **Prof. Dr. Manuel Alcarazo, Prof. Dr. Dirk Schwarzer, Dr. Michael John** and **Dr. Christian Sindlinger** for their work within my thesis committee
- **Prof. Dr. Kenneth Caulton** and **Dr. Nicholas Maciulis** for the friendly acceptance in their work-group within my internship at Indiana University
- **Dr. Christian Würtele** for measuring X-ray crystal structures even sometimes with little chance of success
- **Prof. Dr. Vera Krewald, Dr. Markus Finger** and **Severine Rupp** for performing all theoretical calculations
- **Prof. Dr. Dirk Schwarzer** and **Jan-Hendrik Borter** for running and analyzing the pump-probe spectroscopy experiments
- **Dr. Claudia Stückl** and **Prof. Dr. Joshua Telser** for measuring and simulating EPR spectra
- **Prof. Dr. Christian Limberg, Dr. Christian Herwig** and **Dr. Sebastian Dechert** for recording the Raman-spectra
- **Prof. Dr. Ivana Ivanovic-Burmazovic** and **Dr. Alicja Franke** for their help and support in analyzing and interpreting the UVvis kinetic studies
- **Dr. Michael John** and **Ralf Schöne** for their help and assistance with NMR spectroscopy
- **Dr. Serhiy Demeshko** for measuring and simulating SQUID magnetometry
- **Sebastian Kopp** for his ambitious support in maintaining our laboratory as well as synthesizing my ligand, which saved me a lot of time
- My bachelor- and internship students, **Patricia-Marie Padonou, Jessica Schneider, Katharina Wenderoth** and **Annemarie Kehl**, for their effort in supporting my research and the great time in the lab
- The **European Research Council** (ERC Grant Agreement 646747) for funding

My special thanks go to the whole **AK Schneider** for a fantastic and unforgettable time both inside and outside the lab. Additionally, I want to acknowledge my former office-colleagues (and friends), **Richt Van Alten, Dr. Josh Abbenseth, Dr. Jan Gerkens, Sebastian Kopp** and **Dr. Florian Wätjen** for the inspiring discussions and cooperative atmosphere.

Last but not least, I want to thank my family for their support and patience within the last years.

# Contents

<b>1 Introduction</b>	<b>1</b>
1.1 Bonding of N <sub>2</sub> to transition metals	3
1.1.1 General aspects of N <sub>2</sub> -binding	3
1.1.2 End-on bridging N <sub>2</sub>	4
1.1.3 Side-on bridging N <sub>2</sub>	15
1.2 N <sub>2</sub> -Functionalization	19
1.2.1 Ammonia Formation	19
1.2.2 Thermal N <sub>2</sub> -cleavage into terminal nitrides	27
1.2.3 Photolytic N <sub>2</sub> -cleavage	34
1.3 Nitride-Functionalization	42
1.3.1 Bonding of terminal transition metal nitrides	42
1.3.2 Reactivity of N <sub>2</sub> -derived nitrides	46
1.3.3 Generation of cyanate from N <sub>2</sub> -derived nitrides	52
1.4 Scope of this work	57
<b>2 Results and Discussion</b>	<b>59</b>
2.1 Synthesis and Characterization of N <sub>2</sub> -bridged Ditungsten-PNP-Complexes	59
2.1.1 Redox-series [(N <sub>2</sub> ) <sub>2</sub> {WCl(PNP)} <sub>2</sub> ] <sup>n+</sup> (n = 0-2)	59
2.1.2 Synthesis and characterization of [(N <sub>2</sub> ) <sub>2</sub> {W(CO)(PNP)} <sub>2</sub> ] ( <b>4</b> )	66
2.2 Proton induced N <sub>2</sub> -cleavage <i>versus</i> proton reduction	72
2.3 N <sub>2</sub> -cleavage of [(N <sub>2</sub> ) <sub>2</sub> {W(CO)(PNP)} <sub>2</sub> ] ( <b>4</b> )	83
2.3.1 Thermal N <sub>2</sub> -cleavage	84
2.3.2 Photolytic N <sub>2</sub> -cleavage	89
2.4 Functionalization of tungsten-nitrido-complexes	96
2.4.1 Alternative synthesis of [W(N)(CO)(PNP)] ( <b>16</b> ) <i>via</i> an azide route	96
2.4.2 Functionalization of [W(N)(CO)(PNP)] ( <b>16</b> ) using π-acceptor ligands	100
2.4.3 Mechanistic investigations on CN-bond coupling	102
2.4.4 Liberation of cyanate and closure of the synthetic cycle	105
2.5 Summary and Outlook	110
<b>3 Experimental</b>	<b>115</b>
3.1 General Working Techniques	115
3.2 Analytical Methods	115
3.2.1 Crystallographic details	115
3.2.2 Cyclic voltammetry	116
3.2.3 Electron Paramagnetic Resonance	116
3.2.4 Elemental Analysis	116
3.2.5 Head Space Analysis	116
3.2.6 Irradiation	117
3.2.7 Magnetic measurements	117
3.2.8 Mass spectrometry	117
3.2.9 Nuclear magnetic resonance	117

3.2.10	Quantum yield determination . . . . .	118
3.2.11	Transient UVvis spectra . . . . .	119
3.2.12	Transient IR spectra . . . . .	119
3.2.13	UVvis spectroscopy . . . . .	120
3.2.14	Vibrational spectroscopy . . . . .	120
3.3	Synthesis . . . . .	121

## List of Figures

1	Most frequently found coordination modes in N <sub>2</sub> -complexes. . . . .	3
2	Orbital interactions between N <sub>2</sub> and a metal center in end-on bound N <sub>2</sub> -complexes. . . . .	4
3	Structural and spectroscopic properties of the [(N <sub>2</sub> ){Mo(N(R)Ar) <sub>3</sub> } <sub>2</sub> ] <sup>n+</sup> (n = 0-2)-redox series ( <b>I</b> , <b>II</b> , <b>III</b> ) and the hetero-bimetallic Mo/Nb analogue ( <b>IV</b> ) by <i>Cummins</i> . . . . .	6
4	The PNP-pincer supported N <sub>2</sub> -bridged Mo ( <b>XI</b> ) and Re ( <b>XII</b> ; <b>XIII</b> ) dinuclear complexes reported by <i>Schneider</i> . . . . .	11
5	<i>Sita's</i> isostructural [(N <sub>2</sub> )(MCp*am) <sub>2</sub> ] complexes . . . . .	13
6	<i>left</i> : <i>Chirik's</i> terpyridine supported Mo-N <sub>2</sub> -dimer redox series <b>XVII</b> <sup>n+</sup> (n = 0-4). <i>right</i> : Qualitative FMO scheme of the redox series and the corresponding spin states and NN stretching frequencies. . . . .	14
7	Increased steric shielding of the supporting ligands results in linkage isomerization from side-on to end-on. . . . .	17
8	pK <sub>a</sub> -dependence of the selectivity between N <sub>2</sub> -reduction (NRR, blue) and H <sub>2</sub> -evolution (HER, blue) of <b>XXVla</b> . . . . .	23
9	Pincer-supported Mo-complexes by <i>Schrock</i> ( <b>XXXIV</b> ) and <i>Mezailles</i> ( <b>XXXV</b> ) capable for N <sub>2</sub> -cleavage under reductive conditions. . . . .	29
10	Pincer-supported, square-planar nitrido-complexes reported by <i>Caulton</i> ( <i>left</i> ), <i>Burger</i> ( <i>middle</i> ) and <i>Schneider</i> ( <i>right</i> ). . . . .	44
11	Molecular structure of <b>5</b> . . . . .	59
12	Molecular structure of <b>1</b> . . . . .	60
13	Comparison of the cyclic voltammograms of <b>1</b> (blue) and <b>XI</b> (red) . . . . .	61
14	Molecular structure and EPR-spectrum of <b>2</b> . . . . .	62
15	Molecular structure and χ <sub>M</sub> T vs. T-plot for <b>3</b> -[Al(OC(CF <sub>3</sub> ) <sub>3</sub> ) <sub>4</sub> ] <sub>2</sub> . . . . .	63
16	Spin-density-plots for <b>2</b> ( <i>left</i> ) and <b>3</b> ( <i>right</i> ). . . . .	65
17	<sup>31</sup> P{ <sup>1</sup> H} NMR spectra of the reaction of <b>1</b> with CN- <sup>t</sup> Bu. . . . .	66
18	Molecular structure and CV of <b>8</b> . . . . .	69
19	Molecular structure and χ <sub>M</sub> T vs. T-plot for <b>4</b> . . . . .	70
20	<i>left</i> : qualitative MO-scheme for end-on N <sub>2</sub> -bridged compound with idealized fourfold symmetry. <i>right</i> : Comparison of the structural and spectroscopic features of <b>4</b> , <i>Schneider's</i> ReCl-congener <b>XII</b> and <i>Cummins's</i> neutral <b>I</b> . . . . .	71
21	Molecular structure and EPR-spectrum of <b>11</b> . . . . .	72
22	<sup>31</sup> P{ <sup>1</sup> H} ( <i>left</i> ) and <sup>15</sup> N{ <sup>1</sup> H} NMR spectra ( <i>right</i> ) of <b>12</b> in THF-d <sub>8</sub> at -35 °C. . . . .	75
23	Exemplary UVvis spectrum of the protonation of <b>1</b> and K <sub>1</sub> -determination . . . . .	77
24	abs (607nm) vs time and k <sub>obs(2)</sub> vs c(H <sup>+</sup> ) plots . . . . .	77
25	Plot of the concentration of <b>4</b> vs. time at different temperatures. . . . .	84
26	<i>Van't Hoff</i> - and <i>Eyring</i> -plots for the conversion of <b>4</b> into <b>16</b> . . . . .	85
27	Computed structures of the two isomers found for <b>16</b> . . . . .	86
28	Experimental UVvis spectrum of <b>4</b> in THF. . . . .	89

29	<i>left</i> : Transient UVvis difference spectra of <b>4</b> in THF at selected pump-probe delays (pump wavelength: 475 nm). The black line shows the scaled linear absorption spectrum. <i>right</i> : Time-dependence of the integrated absolute absorption changes (red line is a bi-exponential fit with $\tau_1 = 1.5 \pm 0.2$ ps and $\tau_2 = 9.2 \pm 0.5$ ps). . . . .	90
30	Transient IR difference spectra of <b>4</b> in THF at selected pump-probe delays (pump wavelength: 400 nm). . . . .	91
31	Simplified energy surfaces for a diabatic photoreaction ( <i>left</i> ) and a reaction proceeding <i>via</i> a hot-ground state ( <i>right</i> ). . . . .	92
32	Comparison of the experimental (black) and TD-DFT computed (blue: $S = 0$ ; red: $S = 1$ ) electronic absorption spectra of <b>4</b> . The inset shows the potentially active transitions. . . . .	94
33	<i>left</i> : Difference density plots (loss in yellow, gain in red) for the transitions S15, S16, T13 and T14 calculated for <b>4</b> . <i>right</i> : Simplified MO-scheme for <b>4</b> with the electronic excitation assigned to productive in photolytic $N_2$ -cleavage. . . . .	95

118	$^{13}\text{C}\{^1\text{H}\}$ NMR Spectrum of <b>21</b> in $\text{C}_6\text{D}_6$ at r.t. . . . . .	185
119	$^{15}\text{N}\{^1\text{H}\}$ NMR Spectrum of $^{15}\text{N}$ - <b>21</b> in $\text{C}_6\text{D}_6$ at r.t. . . . . .	186
120	$^{31}\text{P}\{^1\text{H}\}$ NMR Spectrum of <b>21</b> in $\text{C}_6\text{D}_6$ at r.t. . . . . .	186
121	$^{13}\text{C}\{^1\text{H}\}$ ( <i>left</i> ) and $^{31}\text{P}\{^1\text{H}\}$ ( <i>right</i> ) NMR spectra of $^{15}\text{N}$ - <b>21</b> in $\text{C}_6\text{D}_6$ at r.t.	187
122	ATR-IR spectrum of <b>21</b> . The red line represents the ATR-IR spectrum of $^{15}\text{N}$ - <b>21</b> , the blue line shows the spectrum of $(^{13}\text{CO})_2$ - <b>21</b> . . . . . .	187
123	CV of the reduction of <b>21</b> in 0.1 M solution of $[\text{nBu}_4\text{N}][\text{PF}_6]$ in THF (WE = GC, RE = Ag/Ag <sup>+</sup> , CE = Pt) at different scan rates. . . . . .	188
124	$^1\text{H}$ NMR Spectrum of <b>22</b> in $\text{C}_6\text{D}_6$ at r.t. . . . . .	189
125	$^{13}\text{C}\{^1\text{H}\}$ NMR Spectrum of <b>22</b> in $\text{C}_6\text{D}_6$ at r.t. . . . . .	189
126	$^{31}\text{P}\{^1\text{H}\}$ NMR Spectrum of <b>22</b> in $\text{C}_6\text{D}_6$ at r.t. . . . . .	190
127	ATR-IR Spectrum of <b>22</b> . . . . . .	190
128	$^1\text{H}$ NMR Spectrum of <b>23</b> in $\text{C}_6\text{D}_6$ at r.t. . . . . .	191
129	$^{13}\text{C}\{^1\text{H}\}$ NMR Spectrum of <b>23</b> in $\text{C}_6\text{D}_6$ at r.t. . . . . .	191
130	$^{31}\text{P}\{^1\text{H}\}$ NMR Spectrum of <b>23</b> in $\text{C}_6\text{D}_6$ at r.t. . . . . .	192
131	ATR-IR Spectrum of <b>23</b> . . . . . .	192
132	$^1\text{H}$ NMR Spectrum of <b>6</b> in $\text{D}_6\text{D}_6$ at r.t. . . . . .	193
133	$^{13}\text{C}\{^1\text{H}\}$ NMR Spectrum of <b>6</b> in $\text{D}_6\text{D}_6$ at r.t. . . . . .	193
134	$^{31}\text{P}\{^1\text{H}\}$ NMR Spectrum of <b>6</b> in $\text{D}_6\text{D}_6$ at r.t. . . . . .	194
135	ATR-IR Spectrum of <b>6</b> . . . . . .	194
136	$^1\text{H}$ NMR Spectrum of <b>24</b> in THF- $d_8$ at r.t. . . . . .	195
137	$^{13}\text{C}\{^1\text{H}\}$ NMR Spectrum of <b>24</b> in THF- $d_8$ at r.t. . . . . .	195
138	$^{31}\text{P}\{^1\text{H}\}$ NMR Spectrum of <b>24</b> in THF- $d_8$ at r.t. . . . . .	196
139	ATR-IR Spectrum of <b>24</b> . . . . . .	196
140	CV of the first oxidation event of <b>24</b> in 0.1 M solution of $[\text{nBu}_4\text{N}][\text{PF}_6]$ in THF (WE = GC, RE = Ag/Ag <sup>+</sup> , CE = Pt) at different scan rates. . . . . .	197
141	CV of the first two oxidation events of <b>24</b> in 0.1 M solution of $[\text{nBu}_4\text{N}][\text{PF}_6]$ in THF (WE = GC, RE = Ag/Ag <sup>+</sup> , CE = Pt) at different scan rates. . . . . .	197
142	Thermal ellipsoid plot of <b>5</b> with the anisotropic displacement parameters drawn at the 50% probability level. The asymmetric unit contains one complex molecule. . . . . .	198
143	Thermal ellipsoid plot of <b>1</b> with the anisotropic displacement parameters drawn at the 50% probability level. The asymmetric unit contains a half disordered complex molecule. The disordered complex molecule was refined with population of 0.670(3) on the main domain using some restraints (SADI, RIGU). . . . . .	199
144	Thermal ellipsoid plot of <b>2</b> with the anisotropic displacement parameters drawn at the 50% probability level. The asymmetric unit contains one complex molecule, one benzene solvent molecule and one disordered $\text{CF}_3\text{SO}_3^-$ anion with a population of 0.67(1) on the main domain. The structure was refined as twin using the twin law -100 010 00-1 (BASF: 0.47(1)) and some restraints and constrains (SADI, RIGU, EADP). . . . . .	200

145	Thermal ellipsoid plot of <b>3</b> with the anisotropic displacement parameters drawn at the 50% probability level. The asymmetric unit contains a half complex molecule, a half THF solvent molecule, one BPh <sub>4</sub> anion and one disordered THF solvent molecule. The disordered THF molecule was refined with population of 0.506(6) on the main domain using some restraints (SADI, RIGU).....	201
146	Thermal ellipsoid plot of <b>11</b> with the anisotropic displacement parameters drawn at the 50% probability level. The asymmetric unit contains one cationic complex molecule, one CF <sub>3</sub> COO <sup>-</sup> anion and one benzene solvent molecule. The N-H hydrogen atom was found from the residual density map and isotropically refined. ....	202
147	Thermal ellipsoid plot of <b>8</b> with the anisotropic displacement parameters drawn at the 50% probability level. The asymmetric unit contains one disordered complex molecule. The disordered complex molecule was refined with population of 0.845(5) and 0.724(8) on their main domains using some restraints and constraints (SADI, EADP). The structure was refined as an inversion twin using the twin law -100 0-10 00-1 (BASF: 0.307(4)). Reflection 0 2 1 was removed from the refinement using OMIT commands. ....	203
148	Thermal ellipsoid plot of <b>4</b> with the anisotropic displacement parameters drawn at the 25% probability level. The asymmetric unit contains a half disordered complex molecule. The disordered complex molecule was refined with population of 0.799(6) on the main domain using some restraints (SADI, RIGU). ....	204
149	Thermal ellipsoid plot of <b>18</b> with the anisotropic displacement parameters drawn at the 50% probability level. The asymmetric unit contains one disordered complex molecule. The disordered complex molecule was refined with population of 0.9311(9) on the main domain using some restraints and constraints (SADI, EADP). ....	205
150	Thermal ellipsoid plot of <b>20</b> with the anisotropic displacement parameters drawn at the 50% probability level. The asymmetric unit contains one complex molecule one CF <sub>3</sub> SO <sub>3</sub> <sup>-</sup> anion and one toluene solvent molecule. The N-H hydrogen atom was found from the residual density map and isotropically refined. ....	206
151	Thermal ellipsoid plot of <b>21</b> with the anisotropic displacement parameters drawn at the 50% probability level. The asymmetric unit contains one complex molecule. The reflections 2 0 0 and 8 9 16 are removed from the refinement using OMIT commands. ....	207

152	Thermal ellipsoid plot of <b>22</b> with the anisotropic displacement parameters drawn at the 50% probability level. The asymmetric unit contains one disordered complex molecule. The disordered complex molecule was refined with population of 0.67(1) on the main domain using some restraints (RIGU, SADI). The structure was refined as an inversion twin using the twin law -100 0-10 00-1 (BASF: 0.03(1)). . . . .	208
153	Thermal ellipsoid plot of <b>23</b> with the anisotropic displacement parameters drawn at the 50% probability level. The asymmetric unit contains one complex molecule and a half disordered diethyl ether solvent molecule. The disorder was refined using PART -1 command. . . . .	209
154	Thermal ellipsoid plot of <b>6</b> with the anisotropic displacement parameters drawn at the 50% probability level. The asymmetric unit contains two complex molecules. . . . .	210
155	Thermal ellipsoid plot of <b>24</b> with the anisotropic displacement parameters drawn at the 50% probability level. The asymmetric unit contains one complex molecule. The reflections -5 5 6 and -5 5 8 are removed from the refinement using OMIT commands. . . . .	211

## List of Schemes

1	Proposed mechanism of reduction of dinitrogen at the {FeMo}-nitrogenase.	1
2	Mechanism of ammonia formation <i>via</i> the <i>Haber-Bosch-process</i> .	2
3	Influence of the supporting ligands in formation of end-on bridging N <sub>2</sub> -complexes.	5
4	Qualitative Molecular Orbital scheme for S <sub>6</sub> -symmetric N <sub>2</sub> -bridged dinuclear species.	6
5	<i>left</i> : Floriani's N <sub>2</sub> -bridged dinuclear vanadium dimer <b>V</b> .	7
6	Trigonal bipyramidal N <sub>2</sub> -bridged dinuclear species with π <sup>10</sup> -configuration reported by Schrock and Copéret.	8
7	Trigonal bipyramidal N <sub>2</sub> -bridged Ti-complexes with different π-electron count reported by Liddle.	9
8	Qualitative Molecular Orbital scheme for D <sub>4h</sub> -symmetric N <sub>2</sub> -bridged dinuclear complexes.	10
9	<i>left</i> : Qualitative MO-diagramm for D <sub>2h</sub> - or D <sub>2d</sub> -symmetric end-on N <sub>2</sub> -bridged dinuclear compounds. <i>right</i> : Generalized structure of <b>XIV</b> and <b>XV</b> .	12
10	Qualitative Molecular Orbital scheme for D <sub>2h</sub> -symmetric side-on N <sub>2</sub> -bridged dinuclear species. The symmetry of the resulting molecular orbitals (MOs) is indicated by the color with black π-, purple δ-symmetry.	15
11	Linkage isomerization from side-on to end-on by exchange of Cl <sup>-</sup> vs. Cp <sup>-</sup> .	16
12	Different reactivity upon reaction with H <sub>2</sub> depending on the coordination mode of the bridging N <sub>2</sub> -ligand.	17
13	NN-bond cleavage upon addition of CO to a side-on N <sub>2</sub> -bridged <i>ansa</i> -hafnocene-complex <b>XXIII</b> .	18
14	<i>left</i> : Schematic of the FeMo-cofactor of the {FeMo}-nitrogenase. <i>right</i> : Overall reaction for the transformation of N <sub>2</sub> into NH <sub>3</sub> mediated by the {FeMo}-nitrogenase.	19
15	<i>left</i> : Structure of [(N <sub>2</sub> )-Mo(HIPTN <sub>3</sub> N)] ( <b>XXVa</b> ). <i>right</i> : Proposed mechanism for the catalytic formation of NH <sub>3</sub> upon successive protonation/reduction of <b>XXVa</b> ( <i>Schrock-cycle</i> ).	20
16	<i>left</i> : Structures of [Fe(TBP)] <sup>-</sup> ( <b>XXVIa</b> ) and [(N <sub>2</sub> )-Fe(SiP <sub>3</sub> <sup>iPr</sup> )] <sup>-</sup> ( <b>XXVIIa</b> ). <i>right</i> : Proposed mechanistic pathways for the transformation of <b>XXVIb</b> into <b>XXVIk</b> <i>via</i> <b>XXVIId</b> , either <i>via</i> an distal (top) or alternating (bottom) pathway. The dotted arrows illustrate a hybrid pathway between distal and alternating.	21
17	Possible reactions of <b>XXVIc</b> , either leading to NH <sub>3</sub> formation or to H <sub>2</sub> formation.	23
18	<i>left</i> : Reduction of <b>XXVIII</b> results in the formation of end-on N <sub>2</sub> bridged <b>XXVIIIb</b> . <i>right</i> : A proposed key intermediate within the catalytic formation of NH <sub>3</sub> .	24

19	<i>left</i> : Nishibayashi's [MoCl <sub>3</sub> ( <sup>carb</sup> PCP)] ( <b>XXIX</b> ) complex. <i>right</i> : Reduction of [MoX <sub>3</sub> ( <sup>pyr</sup> PNP)] <b>XXVIII</b> with Sml <sub>2</sub> results in N <sub>2</sub> -cleavage and formation of [Mo(N)I( <sup>pyr</sup> PNP)] <b>XXVIIIc</b> . . . . .	25
20	<i>left</i> : The proposed distal mechanism for N <sub>2</sub> -fixation. <i>right</i> : The proposed mechanism for N <sub>2</sub> -fixation <i>via</i> NN-bond cleavage. . . . .	26
21	The first example for N <sub>2</sub> -cleavage reported by Cummins. . . . .	27
22	Molecular orbital scheme for the thermal splitting of <b>I</b> into <b>XXXI</b> <i>via</i> a <i>zig-zag</i> -transition state. . . . .	28
23	The end-on N <sub>2</sub> -bridged dinuclear complexes of Floriani ( <b>XXXIIa</b> ) and Schrock ( <b>VIa</b> ), which are not both capable to cleave the NN-bond thermally. . . . .	29
24	<i>Top</i> : Re-mediated N <sub>2</sub> -cleavage <i>via</i> end-on N <sub>2</sub> -bridged dinuclear <b>XII</b> . <i>Bottom</i> : Postulated EC <sup>N<sub>2</sub></sup> C <sup>Cl</sup> EC <sup>Dim</sup> -mechanism for the formation of <b>XII</b> . . . . .	30
25	Proposed mechanism of proton induced N <sub>2</sub> -splitting. . . . .	31
26	Qualitative frontier molecular orbitals diagramm for <b>XI</b> ( <i>left</i> ), <b>XL</b> ( <i>middle</i> ) and the calculated <i>zig-zag</i> -transition state from <b>XL</b> to <b>XXXVIII</b> ( <i>right</i> ). . . . .	31
27	Oxidative N <sub>2</sub> -cleavage as presented by Masuda. . . . .	32
28	Calculated energies for N <sub>2</sub> -cleavage for <b>XII</b> (black) and <b>XIII</b> (green) <i>via</i> a <i>zig-zag</i> -transition state. . . . .	33
29	Proposed mechanism for the formation of <b>XXXIIb</b> upon irradiation of <b>XXXIIa</b> . . . . .	34
30	Irradiation of <b>I</b> or <b>XXXIIa</b> leads to competitive N-N- and M-N <sub>2</sub> -cleavage and in case of <b>XXXIIa</b> to recombination of <b>XXXIIc</b> and <b>XXXIId</b> to give nitride bridged <b>XXXIIb</b> . . . . .	35
31	Photolytical (R <sup>1</sup> = <sup>i</sup> Pr; R <sup>2</sup> = Me) and thermal (R <sup>1</sup> = Et; R <sup>2</sup> = Ph) N <sub>2</sub> -cleavage of Sita's η <sup>5</sup> -cyclopentadienyl/η <sup>2</sup> -amidinate complexes (M = Mo <b>XVIg</b> , <b>XLVa</b> and W <b>XVIh</b> , <b>XLV</b> ). . . . .	36
32	Photolytical splitting of <b>XLVIIa</b> gives terminal nitride <b>XLVIII</b> , whose oxidation yields in <b>XLVIIb</b> <i>via</i> nitride coupling. . . . .	37
33	Irradiation of <b>XLIXa</b> yields in <b>La</b> and <b>Lb</b> , which subsequently react further to give two equivalents of <b>Lc</b> . . . . .	38
34	Molecular orbital scheme for the cleavage of <b>XLIXa</b> into <b>La</b> and <b>Lb</b> upon elongation of the NN-bond distance. . . . .	39
35	Formation of the N <sub>2</sub> -bridged dinuclear Re-PONOP-species <b>LII</b> and their interconversion into <b>LIIa</b> upon photolysis. . . . .	40
36	<i>left</i> : Qualitative orbital interactions within octahedrally coordinated L <sub>5</sub> MN. <i>right</i> : Qualitative frontier molecular orbital scheme for metal nitrido complexes in tetrahedral, octahedral and square-planar coordination geometries. . . . .	43
37	Simplified molecular orbital schemes for the π-interaction within the metal-nitride-bond. . . . .	44
38	Ligand influence on the nucleophilicity of an Tp-supported Os-nitride. . . . .	45
39	Oxidation of the PNP-pincer-ligand and the Re-center in nucleophilic <b>XXXVII</b> change the nitride-philicity to electrophilic in <b>LXVI</b> . . . . .	46

40	Photolytic cleavage of <b>XLIXa</b> generates a unstable Os(V)-nitride <b>Ld</b> , which subsequently disproportionates and starts a cascade reaction, which finally gives <b>LXVIII</b> . . . . .	47
41	<i>Top</i> : Sequential methylation of N <sub>2</sub> -derived <b>XXXI</b> forms the ethylimido <b>LXXI</b> . <i>Bottom</i> : Generation of CN <sup>-</sup> from <b>XXXI</b> . . . . .	48
42	Synthetic cycle to generate organic nitriles from N <sub>2</sub> . . . . .	48
43	Synthetic cycle for the formation of nitriles from N <sub>2</sub> and acyl chlorides using N <sub>2</sub> -bridged heterobimetallic <b>IV</b> . . . . .	49
44	Synthetic cycle for the generation of acetonitrile from N <sub>2</sub> using a Re-PNP-pincer-platform. . . . .	50

# 1 Introduction

Along with carbon, hydrogen and oxygen, nitrogen is one of the main elements found in organic compounds. Although nitrogen is the most abundant gas in the atmosphere, comprising 78%, it exists in its biologically and chemically most stable dinuclear gaseous form,  $N_2$ , making it hard to manipulate and convert into useful chemicals. Its conversion into a more reactive nitrogen source, ammonia ( $NH_3$ ), by biological, enzymatic “nitrogen fixation” was an essential step in development of life.<sup>1,2</sup>

Industrially, atmospheric dinitrogen is transformed into ammonia *via* the so-called *Haber-Bosch-process* upon reaction with hydrogen in the presence of iron or ruthenium at high pressures (50-200 atm) and temperatures (700-850 K).<sup>3,4</sup> Nowadays, millions of tons of  $NH_3$  are produced of which the major part (approx. 80%) is used for the production of fertilizers setting the foundation for modern agriculture. The remaining part of the so generated ammonia is used for the production of nitrogen-containing industrially relevant organic molecules, building blocks and fine chemicals.<sup>4-6</sup>

For both, the industrial and the biological ammonia production, fundamentally different pathways are proposed. Enzymatic  $N_2$ -fixation is supposed to occur *via* a successive protonation/reduction route (Scheme 1).<sup>2</sup> For this route two possible pathways, either following a distal or an alternating mechanism, are proposed. While in the distal mechanism the terminal N-atom is hydrogenated first and released as  $NH_3$ , in the alternating mechanism both N-atoms are hydrogenated simultaneously.<sup>7</sup>

Inspired by this, homogeneous biomimetic catalysts, which are capable for the transformation of  $N_2$  into ammonia *via* successive protonation/reduction at ambient conditions, have been developed.<sup>8-10</sup>

Scheme 1: Proposed mechanism of reduction of dinitrogen at the {FeMo}-nitrogenase.<sup>7</sup>

---

In the *Haber-Bosch-process* dinitrogen is initially cleaved on the catalyst surface into two surface bound N-atoms followed by successive N-H bond formation (Scheme 2). At not too low temperatures and under “normal”  $N_2/H_2$  partial pressure ratios the rate limiting step within this transformation is the cleavage of the NN-bond at the surface of the Fe catalyst ( $N_{2(ad)} \longrightarrow 2 N_{(ad)}$ ).<sup>4,11</sup>

Scheme 2: Mechanism of ammonia formation *via* the *Haber-Bosch-process*.<sup>4</sup>

Mimicking this mechanism several homogeneous systems capable for full cleavage of the NN-triple bond under formation of a metal-bound nitride, of which some of them can be further functionalized to give ammonia, have been developed.<sup>12-21</sup> Additionally, full cleavage of  $N_2$  to give a metal-bound nitride holds the promise of direct and therefore more atom efficient functionalization of  $N_2$  by avoiding full reduction to ammonia and subsequent re-oxidation to nitrogen-containing higher value molecules.<sup>6,22</sup>

For both pathways understanding of  $N_2$ -binding to transition metals is essential. This topic will be covered in chapter 1.1. The functionalization of  $N_2$  to give ammonia will be described in chapter 1.2.1 focusing on the parameters influencing the selectivity between competing nitrogen- and proton-reduction.

Afterwards the thermal and photolytical splitting of  $N_2$  and the functionalization of the so derived metal-bound nitrides, with focus on CN-coupling, will be discussed.

In order to illustrate the origin of a N-functionality within a compound, all nitrogen-atoms, which could be derived from  $N_2$ , are given in blue.

## 1.1 Bonding of N<sub>2</sub> to transition metals

### 1.1.1 General aspects of N<sub>2</sub>-binding

Molecular dinitrogen N<sub>2</sub>, the most common form of all global nitrogen, is both thermodynamically and kinetically a very stable molecule. It features a high bond dissociation energy (941 kJ·mol<sup>-1</sup>), a high ionization potential (-15.6 eV) and low proton (5.1 eV) and electron (-1.9 eV) affinities. Additionally, N<sub>2</sub> provides no dipole moment, which makes it a rather poor ligand.<sup>23-25</sup>

Nevertheless, since the first published N<sub>2</sub>-complex in 1965, [Ru(NH<sub>3</sub>)<sub>5</sub>N<sub>2</sub>]<sup>2+</sup>, there have been many examples for transition metal complexes bearing dinitrogen as ligand, typically in one of the four most frequently reported coordination modes depicted in Figure 1: **(A)** mononuclear end-on ( $\eta^1\text{-N}_2$ ), **(B)** dinuclear end-on ( $\mu^2\text{:}\eta^1\text{:}\eta^1\text{-N}_2$ ), **(C)** dinuclear side-on ( $\mu^2\text{:}\eta^2\text{:}\eta^2\text{-N}_2$ ) and **(D)** dinuclear side-on-end-on ( $\mu^2\text{:}\eta^1\text{:}\eta^2\text{-N}_2$ ), with **(A)** being predominant.<sup>22,26</sup>

Figure 1: Most frequently found coordination modes in N<sub>2</sub>-complexes.<sup>22</sup>

Due to donation of electron density from the metal center into appropriate antibonding orbitals of the N<sub>2</sub> ligand, the coordination to a metal center leads to weakening (or "activation") of the NN-bond. The degree of activation can be rationalized by the NN stretching frequency and the NN bond length, which should be, according to *Badger's* rule, inversely proportional (Table 1). Additional information about the redox state of the N<sub>2</sub> ligand can be derived by its spin-state due to magnetic coupling to the metal ion(s).<sup>27-29</sup>

Table 1: Bond lengths ( $d_{\text{NN}}$ ) and stretching frequencies ( $\tilde{\nu}_{\text{NN}}$ ) of free and coordinated N<sub>2</sub>-species.<sup>22</sup>

	<i>S</i>	$d_{\text{NN}}$ [Å]	$\tilde{\nu}_{\text{NN}}$ [cm <sup>-1</sup> ]
free N <sub>2</sub>	-	1.10	2331
[N≡N]	0	~1.10-1.20	1700-2331
[N≡N] <sup>-</sup>	1/2	n.a.	n.a.
free H <sub>2</sub> N <sub>2</sub>	-	1.25	1583 / 1529
[N=N] <sup>2-</sup>	1	~1.20-1.35	1200-1700
[N=N] <sup>3-</sup>	1/2	1.40	989-1040
free H <sub>4</sub> N <sub>2</sub>	-	1.45	885
[N-N] <sup>4-</sup>	0	~1.40-1.60	700-1100

## 1.1 Bonding of N<sub>2</sub> to transition metals

The degree of N<sub>2</sub> activation for reported complexes ranges from nearly unactivated neutral N<sub>2</sub> up to highly activated hydrazide (N<sub>2</sub><sup>4-</sup>). Notably, while there are many examples for complexes carrying a diazenide (N<sub>2</sub><sup>2-</sup>) or hydrazide (N<sub>2</sub><sup>4-</sup>) ligand, there are only few examples bearing a N<sub>2</sub><sup>3-</sup>-ligand. Furthermore, the monoanionic N<sub>2</sub><sup>-</sup> was only detected in solid matrices at low temperatures emphasizing the importance of initial multi electron reduction for N<sub>2</sub>-activation.<sup>30-33</sup>

Splitting of N<sub>2</sub> into molecular nitrides requires overall six electrons and typically proceeds *via* the formation of end-on N<sub>2</sub>-bridged complexes (Figure 1, **B**) as key intermediates, which will be discussed in the next chapter.<sup>22</sup>

### 1.1.2 End-on bridging N<sub>2</sub>

The formation of end-on bridging N<sub>2</sub>-complexes typically proceeds in a two step process *via* the coordination of a second metal center to a end-on bound N<sub>2</sub>-moiety. Initial binding of N<sub>2</sub> to one metal center is similar to other diatomic ligands like CO and can be understood as a combination of  $\sigma$ -donation of the lone pair of the N<sub>2</sub>-unit into an empty metal d-orbital with suitable symmetry and  $\pi$ -backdonation from a filled metal d-orbital into an empty  $\pi^*$ -orbital of the N<sub>2</sub> ligand. Differences arise from the much higher HOMO-LUMO gap of N<sub>2</sub> (10.82 eV) compared to other diatomic ligands like CO (9.34 eV), which results in a smaller orbital overlap and weaker activation of the N<sub>2</sub>-moiety.<sup>24</sup> Nevertheless, binding to a metal center increases the electron density on the N<sub>2</sub> ligand and its affinity for binding a second metal ion.<sup>34</sup> Independent studies by the groups of *Cummins* and *Schneider* have shown, that reduction of the end-on bound N<sub>2</sub>-complex can promote and accelerate the formation of end-on N<sub>2</sub> bridged complexes.<sup>35,36</sup>

Figure 2: Orbital interactions between N<sub>2</sub> and a metal center in end-on bound N<sub>2</sub>-complexes.

Another possibility for the formation of such N<sub>2</sub>-bridged compounds is the coupling of two terminal nitrides, the microscopic reverse to N<sub>2</sub>-splitting into terminal nitrides, which is mainly found for late transition metals.<sup>16,37-51</sup>

Since both metal ions get in close proximity the formation of N<sub>2</sub>-bridged dinuclear species can be inhibited by usage of too sterically demanding supporting ligands (Scheme 3, **A**). However, a certain shielding of the metal ion(s) is required to prevent the formation of strong metal-metal bonds, as it has been demonstrated by *Cummins* for a series of differently substituted molybdenum(III) triamide and molybdenum(III) trialkoxide complexes (Scheme 3, **B**).<sup>35,52-56</sup>

## 1.1 Bonding of N<sub>2</sub> to transition metals

In this context, the group could also show that reversible cyclometalation can be used as a strategy to prevent metal-metal bond formation (Scheme 3, **C**).<sup>57</sup>

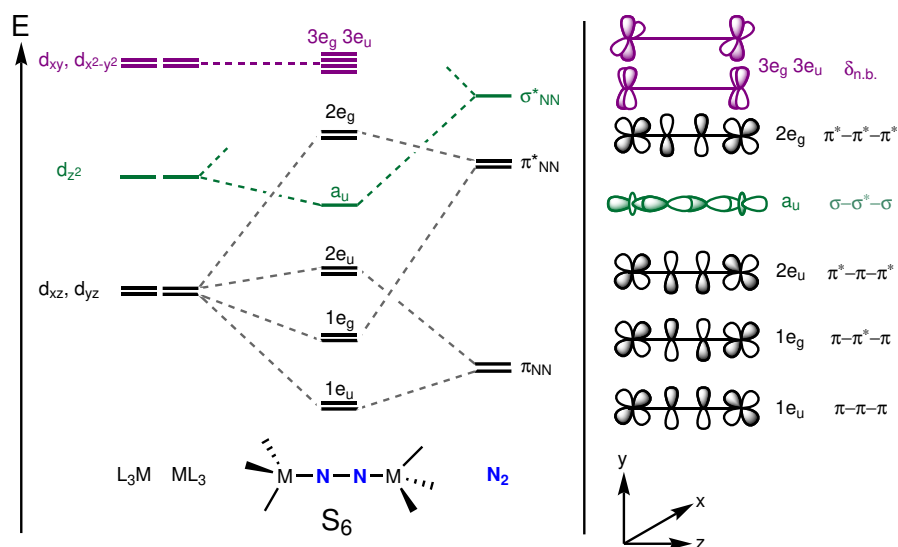

Scheme 3: Influence of the supporting ligands in formation of end-on bridging N<sub>2</sub>-complexes.<sup>35,52–57</sup>

Once formed, the degree of N<sub>2</sub>-activation and therefore the stability of the obtained N<sub>2</sub> bridged complexes can be achieved by consideration of orbital interactions, as first discussed by *Gray* and *Chatt*.<sup>58,59</sup> Thereby, the molecular orbitals are generated from linear combination of the metal d-orbitals and nitrogen p-orbitals. The symmetry of the N<sub>2</sub>-bridged complex has a strong influence on the energetic order of the resulting frontier molecular orbitals (FMOs).

In N<sub>2</sub>-bridged dinuclear species with S<sub>6</sub>-symmetry, linear combination of the d<sub>xz</sub> and d<sub>yz</sub> with the two π and the two π\*-orbitals of the N<sub>2</sub>-ligand results in four sets of π-orbitals (1e<sub>u</sub>, 1e<sub>g</sub>, 2e<sub>u</sub>, 2e<sub>g</sub>) each set consisting of two degenerate orbitals (Scheme 4, black). Additionally, M-N<sub>2</sub>-σ-orbitals (a<sub>u</sub>, Scheme 4, green) are generated by overlap between the d<sub>z<sup>2</sup></sub> orbitals of the two metal centers with the σ\*-orbital of the bridging N<sub>2</sub>-ligand. Due to the lack of N<sub>2</sub>-molecular orbitals with appropriate symmetry, the two remaining d-orbitals of each metal center, d<sub>xy</sub> and d<sub>x<sup>2</sup>-y<sup>2</sup></sub>, give two sets of NN-non-bonding δ-orbitals (3e<sub>g</sub> and 3e<sub>u</sub>) again each set consisting of two degenerate orbitals (Scheme 4, purple).

Taking these simple and qualitative MO considerations to account, the degree of N<sub>2</sub>-activation can be correlated to population of π and π\*-orbitals. A very illustrative example stems from the group of *Cummins*, who investigated the degree of N<sub>2</sub>-activation in a series of Mo-triamido-complexes, [(N<sub>2</sub>){Mo(N(R)Ar)<sub>3</sub>}<sub>2</sub>]<sup>n+</sup>, (R = <sup>t</sup>Bu; Ar = 3,5-C<sub>6</sub>H<sub>3</sub>Me<sub>2</sub>; n = 0 **I**, n = 1 **II**, n = 2 **III**). By comparing the NN-bond lengths and NN-stretching frequencies, an increase of the degree of N<sub>2</sub>-activation was observed with neutral **I** bearing the weakest activated bridging N<sub>2</sub>-ligand within this redox-series (Figure 3). The observed trend can be correlated to the number of π-electrons within the {MoNNMo}-manifold.

## 1.1 Bonding of N<sub>2</sub> to transition metals

Scheme 4: Qualitative Molecular Orbital scheme for S<sub>6</sub>-symmetric N<sub>2</sub>-bridged dinuclear species. The symmetry of the resulting molecular orbitals (MOs) is indicated by the color with green  $\sigma$ -, black  $\pi$ - and purple  $\delta$ -symmetry.<sup>59</sup>

Neutral **I** features overall ten  $\pi$ -electrons, assuming the bridging N<sub>2</sub> ligand to be neutral, both Mo(III)-ions deliver three  $\pi$ -electrons, while the remaining four  $\pi$ -electrons stem from the N<sub>2</sub> ligand itself. Consequently, this electron count results in a  $1e_u^4 1e_g^4 2e_u^2$ -configuration within the {MoNNMo}-manifold with a NN-bonding and M-N<sub>2</sub>-antibonding HOMO ( $2e_u$ ; Scheme 4). Upon oxidation to a  $1e_u^4 1e_g^4 2e_u^1$ - (**II**) or  $1e_u^4 1e_g^4 2e_u^0$ -configuration (**III**), this MO gets depleted, which explains the observed increase in the degree of N<sub>2</sub>-activation upon oxidation.<sup>60,61</sup>

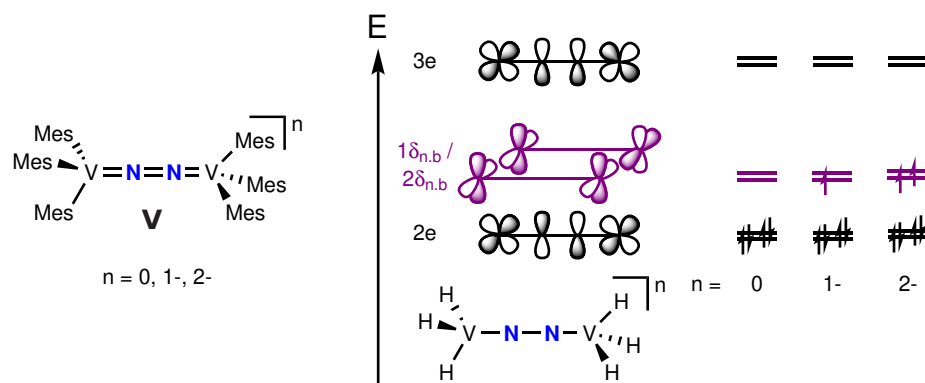

Figure 3: Structural and spectroscopic properties of the  $[(N_2)\{Mo(N(R)Ar)_3\}_2]^{n+}$  ( $n = 0-2$ )-redox series (**I**, **II**, **III**) and the hetero-bimetallic Mo/Nb analogue (**IV**) by *Cummins*.<sup>60-62</sup>

## 1.1 Bonding of N<sub>2</sub> to transition metals

This picture gains further support by magnetic measurements. Neutral **I** features a magnetic moment of  $\mu_{\text{eff}} = 2.85 \mu_{\text{B}}$  in agreement with a triplet ground state.<sup>60</sup> The magnetic moment of monocationic **II** was determined to  $\mu_{\text{eff}} = 1.96 \mu_{\text{B}}$  in line with the expected doublet ground state, while dicationic **III** is diamagnetic.<sup>61</sup>

The group of *Cummins* was also able to prepare a Nb/Mo hetero-bimetallic analogue (**IV**), which has a  $\pi^9$ -configuration isoelectronic to monocationic **II**. Accordingly, the NN-bond length ( $d_{\text{NN}} = 1.235(10) \text{ \AA}$ ) as well as the NN-stretching frequency of **IV** ( $\tilde{\nu}_{\text{NN}} = 1583 \text{ cm}^{-1}$ ) are almost invariant from homobimetallic **II**. Nevertheless, combined DFT and EPR studies showed valence delocalisation of the odd electron over the whole {MoNNNb}-core, further supporting a covalent bonding picture.<sup>62</sup>

The  $\sigma$ - and  $\pi$ -donating abilities of the supporting ligands can have a strong influence on the energetic order of the MO's shown in Scheme 4. This was demonstrated by *Floriani* upon a redox-series of N<sub>2</sub>-bridged dinuclear vanadium compounds (**V**). Neutral **V** has a diamagnetic ground state and features a relatively long NN-bond ( $d_{\text{NN}} = 1.222(4) \text{ \AA}$ ) in line with eight  $\pi$ -electrons fully populating the  $1e_{\text{u}}$ - and  $1e_{\text{g}}$ -orbitals of the {VNNV}-core (Scheme 4). Further reduction giving monoanionic **V<sup>-</sup>** or dianionic **V<sup>2-</sup>** does not lead to significant changes in the NN-bond lengths as it would have been expected by populating the NN-antibonding  $2e_{\text{u}}$ -orbital following the MO-scheme shown in Scheme 4.<sup>63-65</sup>

Scheme 5: *left*: Floriani's N<sub>2</sub>-bridged dinuclear vanadium dimer **V**. *Right*: Qualitative MO-scheme for the truncated  $[(\text{N}_2)\{\text{VH}_3\}_2]$ -model.<sup>63-65</sup>

These differences were rationalized computationally using a truncated  $[(\text{N}_2)\{\text{VH}_3\}_2]$ -model.<sup>63-65</sup> The calculations on the neutral compound revealed a diamagnetic ground state in which the HOMO consists of a set of two degenerate orbitals ( $2e$ , Scheme 5), which are both fully occupied. The LUMO is only about 1 eV higher in energy and features mostly metal  $\delta$ -character. The relatively small energy gap leads to an accessible excited triplet state and second order contributions in the magnetic susceptibility, in agreement with the observed TIP (temperature independent paramagnetism) for **V**. Single electron reduction of **V** leads to population of the  $\delta$ -orbital

## 1.1 Bonding of N<sub>2</sub> to transition metals

and a doublet magnetic ground state. The NN-non-bonding character of this orbital is expressed by a nearly unchanged NN-bond length. Further reduction leads to a ( $1\delta^{1/2}\delta^1$ )-configuration. Again the metal-based character of these orbitals leads to insignificant changes in the NN-bond lengths. The missing contribution of the bridging N<sub>2</sub> ligand in the  $\delta$ -orbitals results in very weak antiferromagnetically coupling of both  $S = 1/2$  centers, in agreement with the observed magnetic behavior of  $\mathbf{V}^{2-}$ .

A fourth auxiliary ligand at the metal center can lead to two different symmetries depending on the coordination sphere around the metal ion. Addition of a ligand *trans* to the bridging N<sub>2</sub>-ligand results in a trigonal bipyramidal coordination sphere around the metal, which can have a strong impact on the stability of the N<sub>2</sub>-bridge with respect to N<sub>2</sub>-cleavage (see chapter 1.2.2). Nevertheless, the fourth ligand *trans* to the N<sub>2</sub>-bridge does not lead to significant changes in the degree of N<sub>2</sub>-activation. For example, both trigonal bipyramidal  $\pi^{10}$ -electron complexes reported by *Schrock* (**Vla**) and *Copéret* (**VII**) feature almost identical NN-bond lengths, very close to those of isoelectronic **I** (Scheme 6).<sup>66,67</sup>

Scheme 6: Trigonal bipyramidal N<sub>2</sub>-bridged dinuclear species with  $\pi^{10}$ -configuration reported by *Schrock* and *Copéret*.<sup>66,67</sup>

## 1.1 Bonding of N<sub>2</sub> to transition metals

The group of *Liddle* reported several Ti-congeners to *Schrock's* **Via** with different  $\pi$ -electron counts (Scheme 7). The bridging N<sub>2</sub> ligand of neutral congener **VIII** with six  $\pi$ -electrons shows only very weak activation ( $d_{\text{NN}} = 1.121(6) \text{ \AA}$ ;  $\tilde{\nu}_{\text{NN}} = 1701 \text{ cm}^{-1}$ ), due to only two electrons occupying the NN-antibonding  $1e_u$ -orbital. In line with the described MO-picture, further reduction to the potassium supported  $\pi^8$ -configured **IX** results in further population of the  $1e_u$ -orbital and an increased degree of N<sub>2</sub>-activation as indicated by the NN-bond length ( $d_{\text{NN}} = 1.315(3) \text{ \AA}$ ) and the NN-stretching frequency ( $\tilde{\nu}_{\text{NN}} = 1201 \text{ cm}^{-1}$ ). Abstraction of the two supporting potassium ions yields in the formation of dianionic **X** with an increased NN-bond distance as well as a slightly increased NN-stretching frequency. Notably, usage of Mg instead of KC<sub>8</sub> as reducing agent does not result in formation of N<sub>2</sub>-bridged species, which illustrates the influence of the used reducing agent and the obtained cation.<sup>68,69</sup>

Scheme 7: Trigonal bipyramidal N<sub>2</sub>-bridged Ti-complexes with different  $\pi$ -electron count reported by *Liddle* (B15C5 = benzo-15-crown-5-ether).<sup>68</sup>

The addition of a fourth auxiliary ligand can also result in square-pyramidal coordination of the metal ions, typically with the N<sub>2</sub>-bridge on the apical side. As a result of the changed symmetry from threefold to fourfold, the orbital overlap with the supporting ligands changes and the  $b_{1u}$ - and  $b_{2g}$ -orbitals drop in energy. Since these orbitals are generated by linear combination of the two metal  $d_{xy}$ -orbitals with  $\delta$ -symmetry, they provide NN-non-bonding character, which has to be taken into account when correlating the overall electron count to the degree of N<sub>2</sub>-activation (Scheme 8).

## 1.1 Bonding of N<sub>2</sub> to transition metals

Scheme 8: Qualitative Molecular Orbital scheme for D<sub>4h</sub>-symmetric N<sub>2</sub>-bridged dinuclear complexes. The symmetry of the resulting molecular orbitals (MOs) is indicated by the color with green  $\sigma$ -, black  $\pi$ - and purple  $\delta$ -symmetry.<sup>59</sup>

Such (idealized) D<sub>4h</sub>-symmetric compounds are often observed, when pincer complexes are used. For example, the group of *Schneider* reported two PNP<sup>tBu</sup>-pincer (PNP<sup>tBu</sup> = [N(CH<sub>2</sub>CH<sub>2</sub>P<sup>t</sup>Bu<sub>2</sub>)<sub>2</sub>]<sup>-</sup>) supported N<sub>2</sub>-bridged dinuclear complexes containing either Mo (**XI**) or Re (**XII**) and therefore different electron counts within the {MNNM}-core (Figure 4).<sup>36,70</sup>

The Mo-compound **XI** contains overall twelve electrons within the {MoNNMo}-core, four stemming from the N<sub>2</sub> ligand itself and two times four electrons from the (formal) Mo(II)-centers. Following the MO-picture (Scheme 8) this results in a  $1e_u^4 1e_g^4 b_{1u}^2 b_{2g}^2$  configuration with a  $\pi$ -electron count of eight. The degree of N<sub>2</sub>-activation is very close to **III** as judged by the NN-bond-length ( $d_{NN} = 1.258(9)$  Å) and NN-stretching frequency ( $\tilde{\nu}_{NN} = 1343$  cm<sup>-1</sup>).<sup>70</sup> Moving from group 6 to group 7, two additional electrons are introduced, which leads to occupation of the  $2e_u$ -orbitals and an overall  $1e_u^4 1e_g^4 b_{1u}^2 b_{2g}^2 2e_u^2$ -configuration with an  $\pi$ -electron count of ten. Accordingly, the degree of N<sub>2</sub>-activation in **XII** is smaller compared to **XI**, as indicated by the shorter NN-bond-length ( $d_{NN} = 1.202(10)$  Å), which is very similar to the one of *Cummins'* neutral **I**.<sup>36</sup>

## 1.1 Bonding of N<sub>2</sub> to transition metals

Figure 4: The PNP-pincer supported N<sub>2</sub>-bridged Mo (**XI**) and Re (**XII**; **XIII**) dinuclear complexes reported by *Schneider*.<sup>36,70,71</sup>

An additional fifth auxiliary ligand *trans* to the N<sub>2</sub>-bridge does not effect the energetic order of the MOs with  $\pi$ - and  $\delta$ -symmetry within the described MO-scheme (Scheme 8). It can therefore be used to rationalize the degree of N<sub>2</sub>-activation in octahedrally coordinated N<sub>2</sub>-bridged dinuclear complexes, like for the weakly activated [(N<sub>2</sub>){Ru(NH<sub>3</sub>)<sub>3</sub>}<sub>2</sub>]<sup>4+</sup> ( $\pi^{12}\delta^4$ ;  $d_{\text{NN}} = 1.12 \text{ \AA}$ ;  $\tilde{\nu}_{\text{NN}} = 2100 \text{ cm}^{-1}$ ) or the strong activated [{(PhMe<sub>2</sub>P)<sub>4</sub>ClRe}(N<sub>2</sub>){MoCl<sub>4</sub>(OMe)}] ( $\pi^8\delta^3$ ;  $d_{\text{NN}} = 1.21 \text{ \AA}$ ;  $\tilde{\nu}_{\text{NN}} = 1660 \text{ cm}^{-1}$ ).<sup>72,73</sup> Nevertheless, the stability of such N<sub>2</sub>-bridged dinuclear species with respect to N<sub>2</sub>-cleavage is increased compared to the square pyramidal analogues. For example, features <sup>i</sup>Pr-substituted and octahedrally coordinated **XIII** (Figure 4) the same electron count and degree of N<sub>2</sub>-activation as its <sup>t</sup>Bu-substituted analogue **XII**, but is thermally stable with respect to N<sub>2</sub> cleavage. A more detailed discussion about the influence of a ligand *trans* to the N<sub>2</sub>-bridge regarding N<sub>2</sub>-cleavage will be given in chapter 1.2.2.<sup>71</sup>

Upon usage of  $\beta$ -diketiminate (nacnac) ligands, several end-on N<sub>2</sub>-bridged dinuclear complexes, bearing late transition metals (Fe, Co, Ni), have been reported.<sup>74–79</sup> Depending on the steric encumbrance of the nacnac-substituents, both {M(nacnac)}-moieties are either coplanar or perpendicular oriented, resulting in an idealized D<sub>2h</sub>- or D<sub>2d</sub>-symmetry, respectively. Furthermore, a distortion from linearity of the {M-N-N-M} is often found, indicating low bending potentials of the core within these type of compounds. The degree of N<sub>2</sub>-activation can be rationalized using the MO-diagramm depicted in Scheme 9.

Assuming the x-axis to be oriented along the {M-N-N-M}-bond, linear combination of the d<sub>xy</sub>- and d<sub>xz</sub>-orbitals with the respective N<sub>2</sub>- $\pi$ -orbitals results in four sets of  $\pi$ -orbitals each set consisting of two degenerate orbitals. The remaining d<sub>yz</sub>, d<sub>z<sup>2</sup></sub> and d<sub>x<sup>2</sup>-y<sup>2</sup></sub>-orbitals form three sets of NN-non-bonding orbitals each consisting of two (nearly) degenerate orbitals, which are all located between the  $\pi_{2-}$  and  $\pi_{3-}$ -level.<sup>80</sup> These considerations are in line with detailed spectroscopic and computational analysis of [(N<sub>2</sub>){Fe(nacnac<sup>t</sup>Bu)}<sub>2</sub>] (**XIVa**), whose overall  $S = 3$  ground state was rationalized by two high-spin Fe(II)-centers ( $S = 2$ ), which are each antiferromagnetically coupled to the bridging N<sub>2</sub><sup>2-</sup>-ligand ( $S = 1$ ), leading to an overall { $\uparrow\uparrow\uparrow\uparrow\downarrow\downarrow\uparrow\uparrow\uparrow\uparrow$ }-three-spin model.<sup>75,80</sup> Accordingly, the relative strong degree of N<sub>2</sub>-activation within

## 1.1 Bonding of N<sub>2</sub> to transition metals

**XIVa** and its Me-substituted congener [(N<sub>2</sub>){Fe(nacnac<sup>Me</sup>)<sub>2</sub>}] (**XVa**) (Table 2, entries 1 and 2) can be explained by a two electron transfer to the N<sub>2</sub>-bridge and a  $(\pi_1)^4(\pi_2)^4(d_{yz}/d_{z^2})^6(d_{x^2-y^2})^2(\pi_3)^2$ -configuration with an overall  $\pi$ -electron count of ten.<sup>74,75,80</sup>

Scheme 9: *left*: Qualitative MO-diagramm for D<sub>2h</sub>- or D<sub>2d</sub>-symmetric end-on N<sub>2</sub>-bridged dinuclear compounds.<sup>80</sup> *right*: Generalized structure of **XIV** and **XV**.

Further reduction is metal centered and leads to full occupation of the  $d_{yz}/d_{z^2}$ -orbitals. However, increased Fe→N<sub>2</sub>-backbonding leads to further weakening of the N<sub>2</sub>-bond (Table 2, entries 3 and 4).<sup>74,75</sup> The same trend was observed for the group 9-congener (Table 2, entries 6 and 7). Compared to the Fe-analogue the degree of N<sub>2</sub>-activation is smaller due to the lower energy of the d-orbitals, which is even more expressed for the Ni-analogue (Table 2, entry 8).<sup>76,77</sup>

Table 2: Comparison of the structural and electronic properties of several nacnac-supported N<sub>2</sub>-bridged dinuclear compounds, M<sub>2</sub>'[(N<sub>2</sub>){M(nacnac<sup>R</sup>)<sub>2</sub>}]<sub>2</sub><sup>X</sup>, and their N<sub>2</sub>-activation parameters.<sup>74–77,79</sup>

## 1.1 Bonding of N<sub>2</sub> to transition metals

The group of *Holland* was also able to abstract the potassium-cations from **XVb**. Thereby the N<sub>2</sub>-bond grows short accompanied by a hypsochromic shift of the NN-stretching frequency, indicating a weaker activation in the absence of a counter-cation within the complex (Table 2, entry 5).<sup>79</sup> However, variation of the alkali-metal in **XVb** showed no significant changes in the degree of N<sub>2</sub>-activation.<sup>74,78</sup> The only difference arises from the different size of the alkali-metal-ions, which leads to twisting and a larger torsion-angle between the {Fe(nacnac<sup>Me</sup>)}-moieties (Na = 0°; Cs = 50.6°).<sup>78</sup> Notably, upon usage of a sterically less encumbered nacnac-ligand, [MeC(CMeNC<sub>6</sub>H<sub>3</sub>-2,6-Me<sub>2</sub>)<sub>2</sub>]<sup>-</sup>, full cleavage of the NN-bond into tetra- or trinuclear bis-μ-nitride complexes was observed.<sup>13,81</sup>

Besides by the number of electrons and the coordination sphere of the metal centers the degree of N<sub>2</sub>-activation is also influenced by the metal itself. This was demonstrated by the group of *Sita* for a series of group 4-6 N<sub>2</sub>-bridged η<sup>5</sup>-cyclopentadienyl/η<sup>2</sup>-amidinate complexes **XVI** (Figure 5). Moving down within a group the degree of N<sub>2</sub>-activation increases as indicated by significantly elongated NN-bond-distances (Table 3). This trend can be explained by the cathodic shift of the oxidation potentials of the metal ions and therefore increased backbonding from the metal to the N<sub>2</sub>-ligand. Similarly, a correlation between the degree of activation and the oxidation potential of the respective metal was also found within a row.<sup>82-85</sup>

Notably, within group 4 the Ti-complex **XVIa** is the only one featuring an end-on bridging μ<sup>2</sup>:η<sup>1</sup>:η<sup>1</sup>-N<sub>2</sub>-ligand, best described as N<sub>2</sub><sup>2-</sup>. In contrast, both higher homologues, Zr (**XVIb**) and Hf (**XVIc**), feature a highly activated side-on bound μ<sup>2</sup>:η<sup>2</sup>:η<sup>2</sup>-N<sub>2</sub>-ligand, which is best described as an N<sub>2</sub><sup>4-</sup>-ligand. The higher degree of activation was assigned to the different oxidation potentials, which renders further oxidation of Ti(III) to Ti(IV), while the side-on coordination was attributed to the larger covalent radii of Zr and Hf (both 1.75 Å) compared to Ti (1.60 Å).<sup>83,86</sup>

## 1.1 Bonding of N<sub>2</sub> to transition metals

The group of *Chirik* illustrated the influence of the supporting ligands based on a redox-series of overall five end-on N<sub>2</sub>-bridged terpyridine supported dinuclear Mo-complexes, [(N<sub>2</sub>)<sub>2</sub>{Mo(Tpy<sup>Ph</sup>)(PMe<sub>2</sub>Ph)<sub>2</sub>}]<sup>n+</sup> (**XVII**<sup>n+</sup>; n = 0-4; Tpy<sup>Ph</sup> = 4'-Ph-2,2',6,6'2"-terpyridine) (Figure 6, *left*). Computational analysis describe dicationic **XVII**<sup>2+</sup> as two Mo(II)-ions bridged by an N<sub>2</sub><sup>2-</sup>-ligand, which is in good agreement with the observed NN-stretching frequency ( $\tilde{\nu}_{\text{NN}} = 1563 \text{ cm}^{-1}$ ) and NN-bond length ( $d_{\text{NN}} = 1.203(2) \text{ \AA}$ ). Due to mixing with the  $\pi$ -system of the terpyridine ligand, the degeneracy of the  $M-\overset{\pi^*}{N}-\overset{\pi^*}{N}-M$  orbitals is lifted, which results in a singlet ground state for **XVII**<sup>2+</sup>. Accordingly, due to removal of an electron from an NN-bonding orbital, oxidation of **XVII**<sup>2+</sup> to **XVII**<sup>3+</sup> results in a significant increase of the degree of N<sub>2</sub>-activation ( $\tilde{\nu}_{\text{NN}} = 1482 \text{ cm}^{-1}$ ). Interestingly, the double oxidation product **XVII**<sup>4+</sup> features an almost identical NN-stretching frequency ( $\tilde{\nu}_{\text{NN}} = 1477 \text{ cm}^{-1}$ ), which was rationalized by removal of an electron from a metal centered b<sub>1u</sub>-orbital in agreement with the observed triplet ground state for **XVII**<sup>4+</sup>. Intriguingly, reduction of **XVII**<sup>2+</sup> also leads in weakening of the NN-bond, which was substantiated by the mainly Tpy<sup>Ph</sup>- $\pi^*$ -character of its LUMO (2b<sub>2g</sub>) and therefore mostly ligand-centered reduction in line with EPR measurements of **XVII**<sup>+</sup> (Figure 6, *right*).<sup>87</sup>

Figure 6: *left*: *Chirik*'s terpyridine supported Mo-N<sub>2</sub>-dimer redox series **XVII**<sup>n+</sup> (n = 0-4). *right*: Qualitative FMO scheme of the redox series and the corresponding spin states and NN stretching frequencies.<sup>87</sup>

1.1.3 Side-on bridging N<sub>2</sub>

Another, but much less common, binding motif of N<sub>2</sub> is the side-on ( $\mu^2:\eta^2:\eta^2\text{-N}_2$ ) coordination mode (Figure 1, **C**).<sup>28,59,88</sup> First evidence for such a binding mode originate from linkage isomerization studies of  $[\{(\text{NH}_3)_5\text{Ru}\}(\text{}^{14/15}\text{N}_2)]^{2+}$ , which are too fast to occur from initial N<sub>2</sub>-dissociation.<sup>37</sup> In 1973 the first structurally characterized side-on bridging N<sub>2</sub>-complex was published.<sup>89,90</sup> Since then various other examples bearing a side-on bridging N<sub>2</sub> ligand have been reported, especially for early transition metals and f-block elements.<sup>18,91-97</sup>

Side-on bridging of N<sub>2</sub> is more complex compared to end-on coordination and often leads to distortion of the  $\{\text{M}_2\text{N}_2\}$ -core from planarity. Similar to the already described end-on bridging mode, the molecular orbitals for the side-on bridging mode can be derived from linear combination of the  $\pi$ -MOs of the N<sub>2</sub> ligand with metal d-orbitals of appropriate symmetry.

Assuming a D<sub>2h</sub>-symmetry with the z-axis oriented along the M-M axis the d<sub>z<sup>2</sup></sub> and d<sub>x<sup>2</sup>-y<sup>2</sup></sub>-orbitals are used for  $\sigma$ -bonding with the ligands of the ML<sub>4</sub>-fragment and with the N<sub>2</sub> ligand. Linear combination of the d<sub>yz</sub>-orbitals with the respective  $\pi_h^*$ -orbital of the N<sub>2</sub> ligand results in formation of two MOs with  $\pi$ -symmetry (Scheme 10, *black*). The d<sub>xy</sub>-orbitals form together with the  $\pi_v^*$ -orbital of the N<sub>2</sub> ligand two MOs with  $\delta$ -symmetry (Scheme 10, *purple*), while the remaining d<sub>xy</sub>-orbitals are non-bonding because of the lack of N<sub>2</sub>-MOs with suitable symmetry (Scheme 10, *grey*).<sup>59</sup>

Scheme 10: Qualitative Molecular Orbital scheme for D<sub>2h</sub>-symmetric side-on N<sub>2</sub>-bridged dinuclear species. The symmetry of the resulting molecular orbitals (MOs) is indicated by the color with black  $\pi$ -, purple  $\delta$ -symmetry.<sup>59</sup>

Overall, the weaker orbital overlap of the  $\delta$ - compared to the  $\pi$ -interactions should result in a energetic preference for end-on coordination. The formation of side-on bridging N<sub>2</sub> ligands can be explained by the absence of an accessible d-orbital suitable to form a second  $\pi$ -bond. This was demonstrated by Fryzuk and coworkers with a pincer supported Zr-N<sub>2</sub>-complex  $[(\text{N}_2)\{\text{Zr}(\text{X})\text{N}(\text{SiMe}_2\text{CH}_2\text{P}^i\text{Pr}_2)_2\}_2]$  (**XVIII**). The chloro-

## 1.1 Bonding of N<sub>2</sub> to transition metals

substituted ( $X = \text{Cl}^-$ , **XVIIIa**) features a side-on bridging N<sub>2</sub> ligand, while the Cp<sup>-</sup>-substituted ( $X = \text{Cp}^-$ , **XVIIIb**) undergoes linkage isomerization to an end-on bridging N<sub>2</sub> ligand (Scheme 11). The side-on coordination in **XVIIIa** originates from strong interaction of the PNP-amide  $\pi$ - and the chloride  $\sigma$ -orbital with the  $d_{yz}$ -orbital. Therefore, this orbital is raised in energy and too high to form a  $\pi$ -bond with the N<sub>2</sub> ligand, which results in  $\delta$ -bonding between the  $d_{xy}$ - and the  $\pi_V^*$ -orbital to stabilize the system. Exchange of the chloro ligand with Cp<sup>-</sup> changes the energetic order of the d-orbitals. The  $d_{yz}$ -orbital drops in energy and becomes available for  $\pi$ -bonding. On the other hand the energy of the  $d_{xy}$ -orbital required for  $\delta$ -bonding is lifted, due to strong interaction with the Cp<sup>-</sup> ligand. The overlap of the PNP-amide  $p$ -orbital is also decreased since the appropriate d-orbital is involved in  $\pi$ -bonding with the N<sub>2</sub> ligand, which leads to significant lengthening of the Zr-N<sup>PNP</sup> bond.<sup>59</sup>

Scheme 11: Linkage isomerization from side-on to end-on by exchange of Cl<sup>-</sup> vs. Cp<sup>-</sup>.<sup>59</sup>

Since both metal centers are in much closer proximity, compared to the end-on bridging mode, the steric shielding of the metal centers plays another important role in the formation of side-on bridging N<sub>2</sub> complexes. Notably, the size of the metal ion itself can also influence coordination mode, as shown by the already mentioned N<sub>2</sub>-bridged  $\eta^5$ -cyclopentadienyl/ $\eta^2$ -amidinate complexes **XVI** by *Sita* (Figure 5). Within group 4, end-on coordination of the bridging N<sub>2</sub>-ligand was only found for the Ti-complex **XVIa**, while both higher homologues, Zr (**XVIb**) and Hf (**XVIc**), feature a side-on bridging N<sub>2</sub>-ligand (Table 3), which was attributed to the larger covalent radii of Zr and Hf (both  $\sim 1.75$  Å) compared to Ti (1.60 Å).<sup>83,86</sup>

Furthermore, the series of differently substituted zirconocenes (**XIX**, Figure 7) by *Chirik* and *Bercaw* demonstrates how the steric encumbrance of the auxiliary ligands can dictate the coordination mode of the bridging N<sub>2</sub>-unit, with bulky substituents preferring the formation of an end-on bridging mode.<sup>98-101</sup>

## 1.1 Bonding of N<sub>2</sub> to transition metals

Figure 7: Increased steric shielding of the supporting ligands results in linkage isomerization from side-on to end-on.<sup>98-101</sup>

Notably, the reactivity of the compounds changes depending on the coordination mode of the bridging N<sub>2</sub> ligand. Reaction of side-on coordinated **XIXa** with 1 atm of H<sub>2</sub> results in formation of the zirconocene hydrazido complex [(μ-N<sub>2</sub>H<sub>2</sub>){Zr(H)Cp'<sub>2</sub>}<sub>2</sub>] (**XX**), which upon heating under H<sub>2</sub>-atmosphere releases NH<sub>3</sub> giving bishydride [Zr(H)<sub>2</sub>Cp'<sub>2</sub>] (**XXIa**). Heating of **XX** in the absence of H<sub>2</sub> yields in cleavage of the NN-bond and formation of [(μ-N)(μ-NH<sub>2</sub>){ZrCp'<sub>2</sub>}<sub>2</sub>] (**XXII**) (Scheme 12). In contrast, reaction of end-on bridged **XIXb** with H<sub>2</sub> leads to loss of the bridging N<sub>2</sub> ligand and formation of a bishydride-complex [Zr(H)<sub>2</sub>Cp'\*C'] (**XXIb**).<sup>101,102</sup>

Similar hydrogenation behavior to **XIXa** was also reported for other complexes bearing a side-on bound N<sub>2</sub>-moiety.<sup>86,103</sup> Furthermore, computational studies imply, that side-on binding is essential for N<sub>2</sub>-hydrogenation.<sup>104</sup>

Scheme 12: Different reactivity upon reaction with H<sub>2</sub> depending on the coordination mode of the bridging N<sub>2</sub>-ligand.<sup>101,102</sup>

## 1.1 Bonding of N<sub>2</sub> to transition metals

Besides hydrogenation, (partial) N<sub>2</sub>-cleavage under the formation of N-E-bonds (E = B, C, Si) has also been reported.<sup>86,103,105-109</sup> In this respect, the group of *Chirik* presented the full cleavage of side-on bound N<sub>2</sub> ligand upon addition of CO to a *ansa*-hafnocene-complex (**XXIII**) (Scheme 13). The first equivalent of CO is proposed to insert into the Hf-N bond. After a retro [2+2]-cycloaddition cyanate (NCO<sup>-</sup>) as well as a reactive vacant coordination site are formed (**XXIV**). This vacant coordination site undergoes intramolecular C-H activation (**XXIVa**), which can be prevented upon addition of a suitable substrate such as H<sub>2</sub> (**XXIVb**). Remarkably, addition of excess CO to **XXIII** results in C-C-bond formation and the oxamide complex (**XXIVc**). Acidic work-up of **XXIVc** releases oxamide (H<sub>2</sub>NC(O)-C(O)NH<sub>2</sub>).<sup>107,108,110</sup>

Scheme 13: NN-bond cleavage upon addition of CO to a side-on N<sub>2</sub>-bridged *ansa*-hafnocene-complex **XXIII**.<sup>107,108,110</sup>

## 1.2 N<sub>2</sub>-Functionalization

### 1.2.1 Ammonia Formation

Even though, N<sub>2</sub> is a very stable and inert molecule, there are some conversions, which are thermodynamically feasible. The most prominent example is the conversion into ammonia.<sup>28</sup>

In nature, this transformation is done at ambient temperature and pressure by three different so-called nitrogenase enzymes, which differ in the composition of their active sites. The most common one, the {FeMo}, employs an iron-molybdenum-sulfur cluster {7Fe-9S-Mo-C-homocitrate} as the active site (Scheme 14), while in the two other less common ones, {FeV} and {Fe-only}, the Mo is replaced by V or Fe, respectively. Under optimal conditions, N<sub>2</sub> is transformed into 2 equiv. NH<sub>3</sub> in a 6H<sup>+</sup>/6e<sup>-</sup> process under the consumption of overall 16 ATP, which underlines the high energy demand to overcome the kinetic barrier for N<sub>2</sub>-fixation. Furthermore, two additional electrons and protons are required for reductive activation of the FeMo-cofactor and initial N<sub>2</sub>-binding under the release of one equivalent of H<sub>2</sub>.<sup>28,29</sup>

Scheme 14: *left*: Schematic of the FeMo-cofactor of the {FeMo}-nitrogenase. *right*: Overall reaction for the transformation of N<sub>2</sub> into NH<sub>3</sub> mediated by the {FeMo}-nitrogenase.<sup>28,29</sup>

Inspired by this, many transition metal catalysts have been developed that are capable for ammonia production upon addition of electrons and protons. Their mechanisms are often not fully understood and/or under current investigation. Two distinct different pathways are proposed, either (similar to the mechanism of the *Haber-Bosch-process*) *via* initial cleavage of the NN-bond under formation of a metal-nitride (see chapter 1.2.2) or *via* successive reduction/protonation of the N<sub>2</sub>-moiety mimicking the reactivity of the nitrogenase.

## 1.2 N<sub>2</sub>-Functionalization

The first stoichiometric examples for these type of mechanism date back to reports by *Chatt*, who first reported the formation of diazine (N<sub>2</sub>H<sub>2</sub>) upon protonation of *trans*-[M(N<sub>2</sub>)<sub>2</sub>(dppe)<sub>2</sub>] (M = Mo or W; dppe = Ph<sub>2</sub>PCH<sub>2</sub>CH<sub>2</sub>PPh<sub>2</sub>) and later the almost quantitative formation of NH<sub>3</sub> upon protonation of *cis*-[M(N<sub>2</sub>)<sub>2</sub>(PMe<sub>2</sub>Ph)<sub>4</sub>] (M = Mo or W). These discoveries lead to the postulation of the so-called *Chatt-cycle* (Chapter 1, Scheme 1), which is also proposed to be the actual mechanism for ammonia formation within the {FeMo}-nitrogenase.<sup>7,111-114</sup>

In 2003, *Schrock* reported the first example for catalytic reduction of N<sub>2</sub> to ammonia using a single site molybdenum catalyst supported by a tetradentate [HIPTN<sub>3</sub>N]<sup>3-</sup> tri-amidoamine ligand ([{3,5-(2,4,6-*i*Pr<sub>3</sub>C<sub>6</sub>H<sub>2</sub>)<sub>2</sub>C<sub>6</sub>H<sub>3</sub>NCH<sub>2</sub>CH<sub>2</sub>}<sub>3</sub>N]<sup>3-</sup>; **XXV**) (Scheme 15), whose sterically demanding ligands prevent the formation of N<sub>2</sub>-bridged-dinuclear complexes.<sup>8</sup>

Scheme 15: *left*: Structure of [(N<sub>2</sub>)-Mo(HIPTN<sub>3</sub>N)] (**XXVa**). *right*: Proposed mechanism for the catalytic formation of NH<sub>3</sub> upon successive protonation/reduction of **XXVa** (*Schrock-cycle*).<sup>8</sup>

Usage of [LutH][BAR<sub>24</sub><sup>F</sup>] ([LutH] = 2,6-lutidinium, [2,6-Me<sub>2</sub>C<sub>5</sub>H<sub>3</sub>NH]<sup>+</sup>; [BAR<sub>24</sub><sup>F</sup>] = [B(3,5-(CF<sub>3</sub>)<sub>2</sub>-C<sub>6</sub>H<sub>3</sub>)<sub>4</sub>]<sup>-</sup>) as proton source and CrCp<sub>2</sub><sup>\*</sup> as reductant gives ammonia in 66% yield (relative to the reductant) in four turn-overs. It was also possible to prepare and characterize several intermediates (**XXVa**, **XXVb**, **XXVc**, **XXVf**, **XXVg**, **XXVk**, **XXVl**) and therefore postulate the so-called *Schrock-cycle* (Scheme 15), which is in agreement with the *Chatt-cycle* (Chapter 1, Scheme 1), although favoring a distal pathway.<sup>8,115</sup>

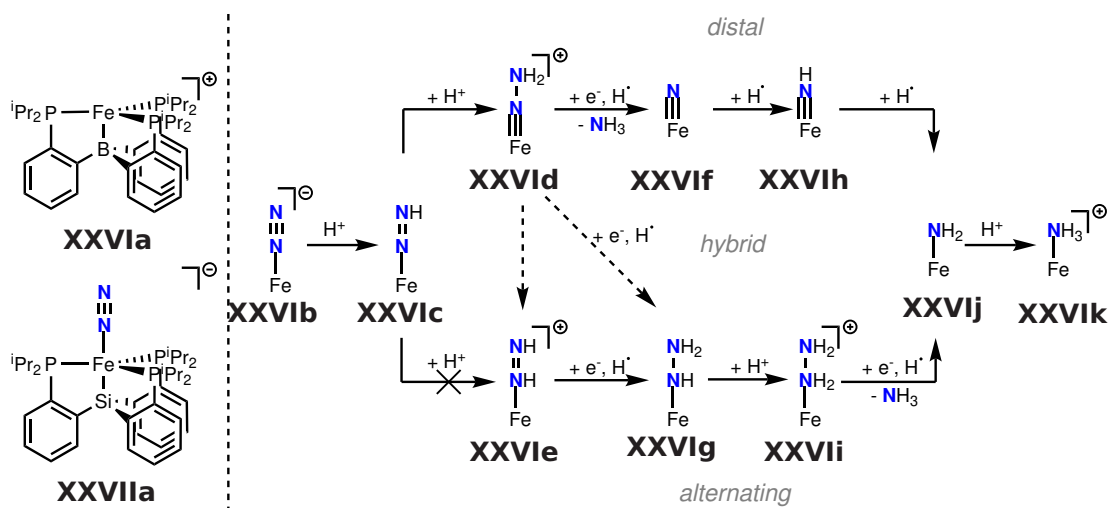

The nature of the used acid has a large influence on the catalytic activity and can even inhibit ammonia-formation at all. For example, usage of [2,6-Et<sub>2</sub>C<sub>5</sub>H<sub>3</sub>NH]<sup>+</sup> gives only 23% of ammonia, while with [2,6-Ph<sub>2</sub>C<sub>5</sub>H<sub>3</sub>NH]<sup>+</sup> or [3,5-Me<sub>2</sub>C<sub>5</sub>H<sub>3</sub>NH]<sup>+</sup> no ammonia is obtained. This effect is attributed to the steric hindrance of the [HIPTN<sub>3</sub>N]-ligand preventing the acid from protonation at the N<sub>y</sub>H<sub>x</sub>-moiety. Too little steric hindrance can lead to side reactions, like proton-reduction, and/or lower the solubility of the acid in unpolar solvents.<sup>115-117</sup>

## 1.2 N<sub>2</sub>-Functionalization

The group of *Schrock* also prepared the other two group 6 as well as the V-congener of [Mo(HIPTN<sub>3</sub>N)] (**XXV**), all showing no catalytic activity in nitrogen reduction to ammonia, although due to different reasons.

Binding of N<sub>2</sub> to the Cr-analogue, [Cr(HIPTN<sub>3</sub>N)], was not observed, most likely due to its high-spin character and the anodic shifted reduction potential of Cr(III) compared to Mo(III).<sup>118</sup> In contrast, the W-analogue [(N<sub>2</sub>)W(HIPTN<sub>3</sub>N)] and several other W-analogues of the proposed intermediates within the *Schrock*-cycle could be prepared. Although most of these intermediates show less stability compared to their Mo-congeners, the first half of the catalytic cycle, the transformation of [(N<sub>2</sub>)W(HIPTN<sub>3</sub>N)] into [N≡W(HIPTN<sub>3</sub>N)] and NH<sub>3</sub>, could be achieved. Catalytic turn-over is believed to be suppressed by the last steps within the cycle. Reduction of [(H<sub>3</sub>N)W(HIPTN<sub>3</sub>N)]<sup>+</sup> even with two equivalents of CoCp<sub>2</sub><sup>\*</sup> does not result in full conversion to [(H<sub>3</sub>N)W(HIPTN<sub>3</sub>N)], which also does not exchange its NH<sub>3</sub> ligand with N<sub>2</sub>.<sup>119</sup> The reason for the lack of catalytic turn-over with the V-congener are attributed to one less overall charge of each intermediate.<sup>120</sup> Overall, these studies illustrate, how certain parameters, like acid-size and -strength, redox-potentials and overall charge, can have a large impact on the catalytic activity of such systems.

Using a structurally related ligand framework, the group of *Peters* presented a single-site Fe-TPB-complex, [Fe(TBP)]<sup>+</sup> (TBP = tris(phosphine)borane; **XXVIa**; Scheme 16, left), capable for the reduction of N<sub>2</sub> into ammonia.<sup>10</sup>

Scheme 16: left: Structures of [Fe(TBP)]<sup>-</sup> (**XXVIa**) and [(N<sub>2</sub>)-Fe(SiPi<sub>3</sub>)]<sup>-</sup> (**XXVIIa**). right: Proposed mechanistic pathways for the transformation of **XXVIb** into **XXVIk** via **XXVIc**, either via an distal (top) or alternating (bottom) pathway. The dotted arrows illustrate a hybrid pathway between distal and alternating.<sup>121</sup>

## 1.2 N<sub>2</sub>-Functionalization

---

Mechanistic studies showed that the initial protonation of [(N<sub>2</sub>)Fe(TBP)]<sup>-</sup> (**XXVib**) gives [(HNN)Fe(TBP)] (**XXVic**), followed by a second protonation of the β-nitrogen to give [(H<sub>2</sub>NN)Fe(TBP)]<sup>+</sup> (**XXVid**), hinting towards a distal mechanism, which is supported by the characterization the terminal Fe(IV)-nitride [(N≡Fe(TBP))<sup>+</sup> (**XXVif**; see also chapter 1.3).<sup>121-123</sup>

However, the mechanistic scenario changes if a more rigid ligand is used. Double protonation of isostructural [(N<sub>2</sub>)Fe(SiP<sup>iPr</sup><sub>3</sub>)]<sup>-</sup> (SiP<sup>iPr</sup><sub>3</sub> = tris(2-(diisopropylphosphino)phenyl)silyl<sup>-</sup>; **XXVIIa**), in which the linking borane is exchanged with silyl, gives rise to the structurally characterized [(H<sub>2</sub>NN)Fe(SiP<sup>iPr</sup><sub>3</sub>)]<sup>+</sup> (**XXVIIb**), in line with a distal pathway. Notably, **XXVIIb** disproportionates with its neutral, one electron reduced congener [(H<sub>2</sub>NN)Fe(SiP<sup>iPr</sup><sub>3</sub>)] (**XXVIIc**) to give [(N<sub>2</sub>)Fe(SiP<sup>iPr</sup><sub>3</sub>)] (**XXVIId**) and [(H<sub>2</sub>NH<sub>2</sub>N)Fe(SiP<sup>iPr</sup><sub>3</sub>)]<sup>+</sup> (**XXVIIe**), a typical intermediate within a alternating pathway, which was rationalized with a hybrid mechanism. The different mechanistic pathways are attributed to the high rigidity of the silyl-bridge, which does not allow the formation of an tetrahedrally coordinated Fe(IV)-nitride.<sup>123,124</sup>

In the first reports for catalytic ammonia formation using **XXVib** as catalyst [H(OEt<sub>2</sub>)<sub>2</sub>][BAR<sub>24</sub><sup>F</sup>] (pK<sub>a</sub> ≈ 0) and KC<sub>8</sub> (E° ≤ -3.0 V vs. Fc<sup>+</sup>/Fc) were used as proton- and electron-source, respectively. In this way up to 7.0 equivalents of ammonia (per Fe) could be obtained.<sup>10</sup> Later, it was discovered that metallocene based reductants can be protonated and that these protonated species feature low CH-bond dissoziation energies (BDE's) (*endo/exo*-[CoCp\*(η<sup>4</sup>-C<sub>5</sub>Me<sub>5</sub>H)]<sup>+</sup> = 31 kcal·mol<sup>-1</sup>; *endo*-[CrCp\*(η<sup>4</sup>-C<sub>5</sub>Me<sub>5</sub>H)]<sup>+</sup> = 37 kcal·mol<sup>-1</sup>; *exo*-[CrCp\*(η<sup>4</sup>-C<sub>5</sub>Me<sub>5</sub>H)]<sup>+</sup> = 30 kcal·mol<sup>-1</sup>) making them potential proton-coupled-electron-transfer (PCET) reagents. In this way, the selectivity over competitive H<sub>2</sub>-evolution (due to proton reduction) and the yield of ammonia could be increased, even though the overall driving force was lowered due to usage of a weaker reductant (CoCp<sub>2</sub><sup>\*</sup>, E° ≤ -1.96 V vs. Fc<sup>+</sup>/Fc) and acid ([Ph<sub>2</sub>NH<sub>2</sub>][OTf], pK<sub>a</sub> = 3.2).<sup>125</sup>

Additionally, different anilinium acids over a wide pK<sub>a</sub>-range were tested revealing a correlation of the selectivity between N<sub>2</sub>-reduction (NRR) and H<sub>2</sub>-evolution (HER) with the pK<sub>a</sub> of the used acid (Figure 8). The weakest acid ([<sup>4</sup>-OMePhNH<sub>3</sub>][OTf], pK<sub>a</sub> = 8.8) was found to be inactive in the formation of NH<sub>3</sub>, while slightly stronger acids ([PhNH<sub>3</sub>][OTf], pK<sub>a</sub> = 7.8; [<sup>2,6</sup>-MePhNH<sub>3</sub>][OTf], pK<sub>a</sub> = 6.8 or [<sup>2</sup>-ClPhNH<sub>3</sub>][OTf], pK<sub>a</sub> = 5.6) showed an increase of the selectivity for NH<sub>3</sub> by lowering the pK<sub>a</sub>. The selectivity and yield for ammonia with even stronger acids ([<sup>2,5</sup>-ClPhNH<sub>3</sub>][OTf], pK<sub>a</sub> = 4.3; [<sup>2,6</sup>-ClPhNH<sub>3</sub>][OTf], pK<sub>a</sub> = 3.4 or [<sup>2,4,6</sup>-ClPhNH<sub>3</sub>][OTf], pK<sub>a</sub> = 2.1) is high and almost independent to the acid strength within this range. Notably, the yield and selectivity for ammonia drops again for the strongest acid within this study ([<sup>per</sup>-ClPhNH<sub>3</sub>][OTf], pK<sub>a</sub> = 1.3), which was explained by an outer sphere electron transfer (ET), that is preferred over a potential protonation of the CoCp<sub>2</sub><sup>\*</sup>.<sup>126</sup>

## 1.2 N<sub>2</sub>-Functionalization

Figure 8: pK<sub>a</sub>-dependence of the selectivity between N<sub>2</sub>-reduction (NRR, blue) and H<sub>2</sub>-evolution (HER, blue) of **XXVla**.<sup>126</sup>

For all other acids a competitive branch within their postulated mechanism for NH<sub>3</sub>-formation, which can lead to H<sub>2</sub>-evolution, is postulated (Scheme 17). Hence, initially formed [(NN)Fe(TBP)]<sup>-</sup> (**XXVib**) is protonated once to give very unstable, neutral [(HNN)Fe(TBP)] (**XXVic**). In the absence of another proton (due to bad solubility of the acid) to form more stable [(H<sub>2</sub>NN)Fe(TBP)]<sup>+</sup> (**XXVid**), **XXVic** reacts bimolecularly to give H<sub>2</sub> and [(NN)Fe(TBP)] (**XXVII**) (Scheme 17, *bottom*). Accordingly, addition of only one equivalent of acid to **XXVib** results exclusively in H<sub>2</sub>-evolution. Furthermore, usage of excess [2.6-ClPhNH<sub>3</sub>]<sup>+</sup> to **XXVib** results depending on the anion and solubility of the acid in different products. While upon protonation with excess of good soluble [2.6-ClPhNH<sub>3</sub>][BAR<sub>24</sub><sup>F</sup>] **XXVid** and fixed-*N*-products could be detected, such species are absent with badly soluble [2.6-ClPhNH<sub>3</sub>][OTf]. However, these findings are in contradiction to the observed high yields of ammonia with [2.6-ClPhNH<sub>3</sub>][OTf] under catalytic conditions in the presence of CoCp<sub>2</sub><sup>\*</sup> (13.8 ± 0.9 equiv. NH<sub>3</sub>/Fe, Figure 8) implying that the CoCp<sub>2</sub><sup>\*</sup> or its protonated form, [CoCp<sup>\*</sup>(η<sup>4</sup>-C<sub>5</sub>Me<sub>5</sub>H)]<sup>+</sup>, are involved in the formation of NH-bonds.<sup>126</sup>

Scheme 17: Possible reactions of **XXVic**, either leading to NH<sub>3</sub> formation or to H<sub>2</sub> formation.<sup>126</sup>

## 1.2 N<sub>2</sub>-Functionalization

Another example for the influence of the anion on the selectivity, either giving H<sub>2</sub> or NH<sub>3</sub>, was reported by the group of *Nishibayashi* using molybdenum supported by a pyridine based PNP-pincer ligand (**XXVIII**). Reduction of the Mo(III) precursor, [MoX<sub>3</sub>(<sup>py</sup>PNP)] (**XXVIIIa**, X = Cl, Br, I), in the presence of N<sub>2</sub> results in the formation of end-on N<sub>2</sub> bridged dinuclear **XXVIIIb** (Scheme 18).<sup>9</sup>

Scheme 18: *left*: Reduction of **XXVIII** results in the formation of end-on N<sub>2</sub> bridged **XXVIIIb**. *right*: A proposed key intermediate within the catalytic formation of NH<sub>3</sub>.<sup>9</sup>

**XXVIIIb** is capable for the catalytic formation of ammonia in the presence of a reductant and a proton source. Upon variation of the acid, while keeping the reductant (CoCp<sub>2</sub>) constant, a large influence of the acid on the activity (equiv.(NH<sub>3</sub>+H<sub>2</sub>) per catalyst) and selectivity (NH<sub>3</sub>/H<sub>2</sub>) was observed. Similar to the report of *Peters* an influence of the pK<sub>a</sub> was found, although without any clear trend. The strongest used acid (HOTf, Table 4, entry 1) features only low activity, but with a relatively high selectivity for ammonia. Upon usage of weaker acids, [pyrH]OTf, [2-picH]OTf or [LutH]OTf (Table 4, entries 2-4), the selectivity for NH<sub>3</sub> drops, while the overall activity is increased.<sup>9</sup>

Notably, both selectivity and activity are not only depending on the acid strength, but also on the corresponding acid-anion, as demonstrated upon usage of different lutidinium salts (Table 4, entries 4-6). Within this series, [LutH][BAR<sub>24</sub><sup>F</sup>] provides the lowest preference for ammonia, although the overall activity is high. Compared to that, [LutH]OTf gives a slightly increased overall activity with a almost equal amounts of NH<sub>3</sub> and H<sub>2</sub>. The highest NH<sub>3</sub> to H<sub>2</sub> ratio was found upon usage of [LutH]Cl. Nevertheless, the overall activity is the lowest of all used acids within this study.<sup>9</sup>

Table 4: Acid influence on the selectivity (NH<sub>3</sub>/H<sub>2</sub>) and activity (equiv.(NH<sub>3</sub>+H<sub>2</sub>) per catalyst) upon usage of **XXVIIIb** under catalytic conditions. (pyr = pyridine, 2-pic = 2-methyl pyridine, Lut = 2,6-dimethyl pyridine).<sup>9</sup>

$$\text{N}_2 + \text{CoCp}_2 + \text{HX} \xrightarrow[\text{tol, r.t.}]{\text{cat.}} \text{NH}_3 + \text{H}_2$$

entry	HX	pK <sub>a</sub> (in MeCN)	NH <sub>3</sub> / H <sub>2</sub>	NH <sub>3</sub> + H <sub>2</sub> [mol. equiv. / cat.]
1	HOTf	2.6	1.55	2.8
2	[pyrH]OTf	12.6	0.19	24.3
3	[2-picH]OTf	13.9	0.55	25.7
4	[LutH]OTf	14.4	0.88	25.2

## 1.2 N<sub>2</sub>-Functionalization

Similar to the reports by *Peters*, a huge increase of the catalytic activity was observed upon usage of PCET-reagents. But instead of protonated metallocenes the group of *Nishibayashi* utilized a combination of SmI<sub>2</sub> and alcohols or water, which feature low OH-bond strengths due to coordination to the Sm(II)-center. For example, the OH-bond strength of free water (111 kcal·mol<sup>-1</sup>) drops in [Sm(OH<sub>2</sub>)<sub>n</sub>]<sup>2+</sup><sub>(aq)</sub> to only 26 kcal·mol<sup>-1</sup>.<sup>127</sup> In this way the group of *Nishibayashi* was able to increase the yield of ammonia up to 42.8 equiv. (per **XXVIIIa**). The yield was even more increased upon usage of a related carbene supported catalyst, [MoCl<sub>3</sub>(<sup>carb</sup>PCP)] (**XXIX**, Scheme 19, *left*). Together with a combination of SmI<sub>2</sub> and H<sub>2</sub>O (both 14400 equiv. based on **XXIX**) 4350 equiv. of ammonia together with only 150 equiv. of H<sub>2</sub> (per **XXIX**) could be obtained, which sets today's record for the most effective homogeneous catalyst for ammonia formation from N<sub>2</sub>.<sup>19</sup>

Scheme 19: *left*: *Nishibayashi's* [MoCl<sub>3</sub>(<sup>carb</sup>PCP)] (**XXIX**) complex. *right*: Reduction of [MoX<sub>3</sub>(<sup>pyrr</sup>PNP)] **XXVIII** with SmI<sub>2</sub> results in N<sub>2</sub>-cleavage and formation of [Mo(N)I(<sup>pyrr</sup>PNP)] **XXVIIIc**.<sup>19</sup>

The catalytic cycle is not fully understood, but two distinct different pathways have been discussed. Early studies of **XXVIII** proposed a distal mechanism, similar to the ones already discussed, in which a thermally bound N<sub>2</sub>-moiety is successively protonated and reduced to give the corresponding nitride (**XXVIIIc**) and one equivalent NH<sub>3</sub>. Further protonation and reduction gives a second equivalent of NH<sub>3</sub> and closes the cycle upon N<sub>2</sub>-binding (Scheme 20, *left*).<sup>9,128,129</sup>

## 1.2 N<sub>2</sub>-Functionalization

Novel studies demonstrated that reduction of [Mo]<sub>3</sub>(<sup>pyr</sup>PNP)] (**XXVIII**d) in the presence of N<sub>2</sub> results in N<sub>2</sub>-cleavage and formation of [Mo(N)](<sup>pyr</sup>PNP)] (**XXVIII**c). These findings lead to the formulation of an alternative, *Haber-Bosch*-type, mechanism in which the bridging N<sub>2</sub> ligand is initially cleaved followed by successive protonation and reduction of the formed nitride to give ammonia (Scheme 20, *right*).<sup>19,130</sup>

Scheme 20: *left*: The proposed distal mechanism for N<sub>2</sub>-fixation.<sup>9,128,129</sup> *right*: The proposed mechanism for N<sub>2</sub>-fixation via NN-bond cleavage.<sup>130</sup>

Besides its potential role within catalytic ammonia formation, dinitrogen splitting into molecular nitrides holds also the promise of direct incorporation of N<sub>2</sub> into organic molecules. Even though, metal nitrides are well known compounds and their reactivity has been widely studied, their direct synthesis from N<sub>2</sub> remains a challenging task, which will be discussed in the next chapter.<sup>131</sup>

1.2.2 Thermal N<sub>2</sub>-cleavage into terminal nitrides

Splitting of dinitrogen into terminal molecular nitrides typically occurs *via* formation of end-on bridged dinuclear complexes. The first example for such a reaction was presented by *Cummins* in 1996. Reaction of [Mo(N(R)Ar)<sub>3</sub>] (R = <sup>t</sup>Bu; Ar = 3,5-C<sub>6</sub>H<sub>3</sub>Me<sub>2</sub>, **XXX**) with N<sub>2</sub> at low temperatures gives the already mentioned end-on N<sub>2</sub>-bridged [(N<sub>2</sub>){Mo(N(R)Ar)<sub>3</sub>}<sub>2</sub>] (**I**). Upon warming to r.t. the NN-bond is cleaved to give the respective Mo(VI)-nitride [Mo(N)(N(R)Ar)<sub>3</sub>] (**XXXI**) in almost quantitative yield (Scheme 21).<sup>12</sup> Counterintuitively, even though the mono- and dioxidized analogues, **II** and **III**, are more activated, they are both stable with respect to N<sub>2</sub>-cleavage due to the lack of electrons to form stable Mo(VI)-nitrides.<sup>60,61</sup>

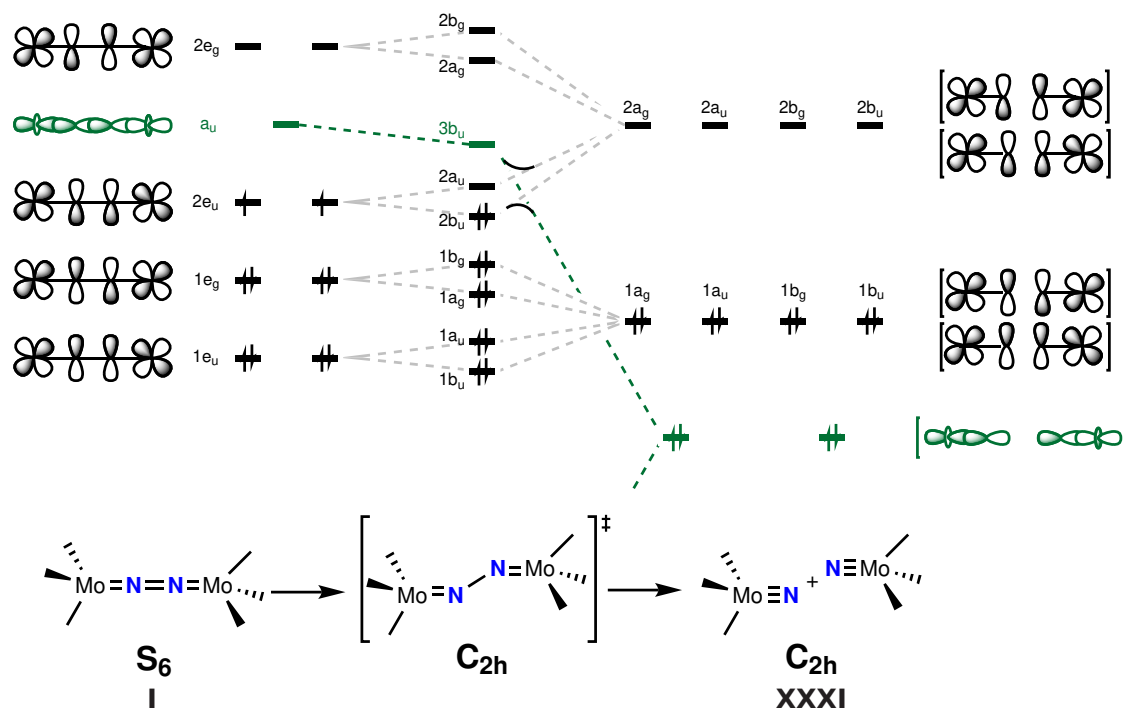

Scheme 21: The first example for N<sub>2</sub>-cleavage reported by *Cummins*.<sup>12</sup>

Further rationalization of the N<sub>2</sub>-splitting process can be achieved by comparing the electronic configurations of the N<sub>2</sub>-bridged species with the ones of the respective nitrides (Scheme 22). As already described in chapter 1.1.2, the molecular orbitals of end-on N<sub>2</sub>-bridged dinuclear complexes can be obtained by linear combination of the metal d-orbitals and nitrogen p-orbitals. In case of *Cummins*' S<sub>6</sub>-symmetric **I** this results in a π<sup>10</sup>-configuration and a triplet ground state (Scheme 22, *left*). In comparison, the formed nitrides are diamagnetic with eight electrons populating the π-manifold. Furthermore the former {σ-σ\*-σ}-orbital (a<sub>u</sub>) drops in energy, becomes populated and forms the σ-bond of the nitride moiety (Scheme 22, *right*). Accordingly, N<sub>2</sub>-splitting occurs *via* electron transfer from a π- into a σ-bonding framework. Since such an electron transfer should be symmetry forbidden, breakage of the NN-bond cannot occur on a linear trajectory. Instead distortion to a C<sub>2h</sub>-symmetric *zig-zag*-transition state should lift the degeneracy of the orbital sets and enable σ/π-transfer by avoided crossing.<sup>60,132</sup>

These considerations are supported by computational analysis by *Morokuma* using truncated [(N<sub>2</sub>){Mo(NH<sub>3</sub>)<sub>3</sub>}<sub>2</sub>], which characterizes the *zig-zag*-transition state as a singlet with NN-single-bond character.<sup>132</sup>

## 1.2 N<sub>2</sub>-Functionalization

Scheme 22: Molecular orbital scheme for the thermal splitting of **I** into **XXXI** via a zig-zag-transition state.<sup>60</sup>

The (thermal) stability with respect to N<sub>2</sub>-cleavage does not only rely on the number of electrons within the {MNNM}- $\pi$ -system, but also on the energy gap between the 2e<sub>u</sub>- and a<sub>u</sub>-orbitals. One possibility to tune this gap is by exchanging the supporting ligands, as shown by *Floriani*. [(N<sub>2</sub>){Mo(Mes)<sub>3</sub>}]<sub>2</sub> (Mes = 2,4,6-C<sub>6</sub>H<sub>2</sub>, **XXXIIa**) is isostructural to **I** and features also 10  $\pi$ -electrons, nevertheless it does not cleave the NN-bond thermally to give the respective nitride **XXXIIb** (Scheme 23). This can be rationalized by the weaker  $\sigma$ - and  $\pi$ -donor abilities of the mesityl-ligands compared to the amide-ligands in **I**, which should lower the energy of the 2e<sub>u</sub>-orbital and thereby increase the energy gap to the a<sub>u</sub>-orbital.<sup>133</sup>

The introduction of a fourth supporting ligand *trans* to the N<sub>2</sub>-bridge has a similar effect. As already mentioned, *Schrock's* **Vla** features almost the same degree of N<sub>2</sub>-activation as *Cummins' I* due to the similarity of the ancillary ligands and the same  $\pi$ -electron count. However, the fourth ligand *trans* to the N<sub>2</sub>-bridge increases the energy of the a<sub>u</sub>-orbital, which hampers mixing with the 2e<sub>u</sub>-orbitals. Besides this kinetic influence, splitting of **Vla** is also thermodynamically less favored and even calculated to be endothermic due to the amine donor *trans* to the formed nitride-ligand (**XXXIII**).<sup>66,132,134</sup>

## 1.2 N<sub>2</sub>-Functionalization

Scheme 23: The end-on N<sub>2</sub>-bridged dinuclear complexes of *Floriani* (**XXXIIa**) and *Schrock* (**VIa**), which are not both capable to cleave the NN-bond thermally.<sup>66,132–134</sup>

Changing the symmetry from threefold to fourfold, which is (idealized) most commonly found for pincer-ligands, the overall number of electrons within the {MNNM}-manifold required for N<sub>2</sub>-cleavage is increased. For example, feature both Mo-ions in *Nishibayashi's* already mentioned octahedral [Mo<sub>2</sub>(<sup>pyr</sup>PNP)] (**XXVIIIc**) and *Cummins'* trigonal planar [Mo(N(R)Ar)<sub>3</sub>] (**XXX**) formally the same oxidation state (+III), but only the latter is capable for direct N<sub>2</sub>-binding and -cleavage. In contrast, **XXVIIIc** requires the addition of two electrons to give the respective Mo(IV)-nitride **XXVIIIb** (Scheme 19).<sup>130</sup> Similar observations have been made for related pincer supported Mo(III)-complexes by the groups of *Schrock* (**XXXIV**), *Mezailles* (**XXXV**, Figure 9).<sup>14,17</sup>

Figure 9: Pincer-supported Mo-complexes by *Schrock* (**XXXIV**) and *Mezailles* (**XXXV**) capable for N<sub>2</sub>-cleavage under reductive conditions.<sup>14,17</sup>

However, isolation and characterization of any N<sub>2</sub>-bridged intermediate was not possible so far for any of those systems, which leaves the electronic configuration required for N<sub>2</sub>-cleavage unsettled. Following the already discussed MO-scheme (Scheme 8), the energies of the NN-non-bonding b<sub>1u</sub> and b<sub>2g</sub>-δ-orbitals drop below the 2e<sub>u</sub>-orbital, due to the changed symmetry. Accordingly and under the assumption of a low spin configuration four additional electrons are required to reach a π<sup>10</sup>δ<sup>4</sup>-configuration. Splitting would therefore occur from formal Mo(I)/Mo(I)-stage directly into the respective Mo(IV)-nitrides in all three cases.

These electronic considerations are supported by studies on N<sub>2</sub>-binding and -cleavage using the already mentioned [ReCl<sub>2</sub>(PNP<sup>tBu</sup>)] (**XXXVI**) by the groups of *Miller*, *Siewert* and *Schneider*. Combined electrochemical and computational analysis suggest an EC<sup>N<sub>2</sub></sup>Cl<sup>EC<sup>Dim</sup></sup>-mechanism for the formation of the structurally characterized N<sub>2</sub>-bridged **XII** (Scheme 24), which is capable for N<sub>2</sub>-cleavage.

## 1.2 N<sub>2</sub>-Functionalization

In the first step the Re(III)-starting complex (**XXXVI**) gets reduced to the Re(II)-stage accompanied by N<sub>2</sub>-binding and chloride-loss. The so formed [ReCl(N<sub>2</sub>)(PNP)<sup>tBu</sup>] has a less negative reduction potential ( $\Delta E \approx 0.4$  V) compared to starting material **XXXVI** and is therefore reduced to [ReCl(N<sub>2</sub>)(PNP)<sup>tBu</sup>]<sup>-</sup>. Binding of another [ReCl<sub>2</sub>(PNP)<sup>tBu</sup>] (**XXXVI**) leads to comproportionation of both Re-centers, loss of another chloride-ligand and formation of dinuclear **XII**, which finally gives the respective Re(V)-nitride (**XXXVII**) via N<sub>2</sub>-cleavage. Accordingly, splitting occurs on a formal Re(II)/Re(II)-stage supporting the requirement of a  $\pi^{10}\delta^4$ -configuration in a fourfold symmetry for N<sub>2</sub>-cleavage.<sup>15,36</sup>

Scheme 24: *Top*: Re-mediated N<sub>2</sub>-cleavage via end-on N<sub>2</sub>-bridged dinuclear **XII**. *Bottom*: Postulated EC<sup>N<sub>2</sub></sup>C<sup>Cl</sup>EC<sup>Dim</sup>-mechanism for the formation of **XII**.<sup>15,36</sup>

An alternative scenario, using the b<sub>1u</sub> and b<sub>2g</sub>- $\delta$ -orbitals as electron reservoir, was suggested by *Schrock*. In this case, splitting was proposed to occur from a formal Mo(II)/Mo(II)-stage into the respective Mo(V)-nitride, followed by subsequent reduction to the corresponding Mo(IV)-nitride. Hence, splitting is induced by a metal to ligand charge transfer from a singlet  $\pi^8\delta^4$ - into a quintet  $\pi^{10}\delta^2$ -configuration.<sup>14</sup>

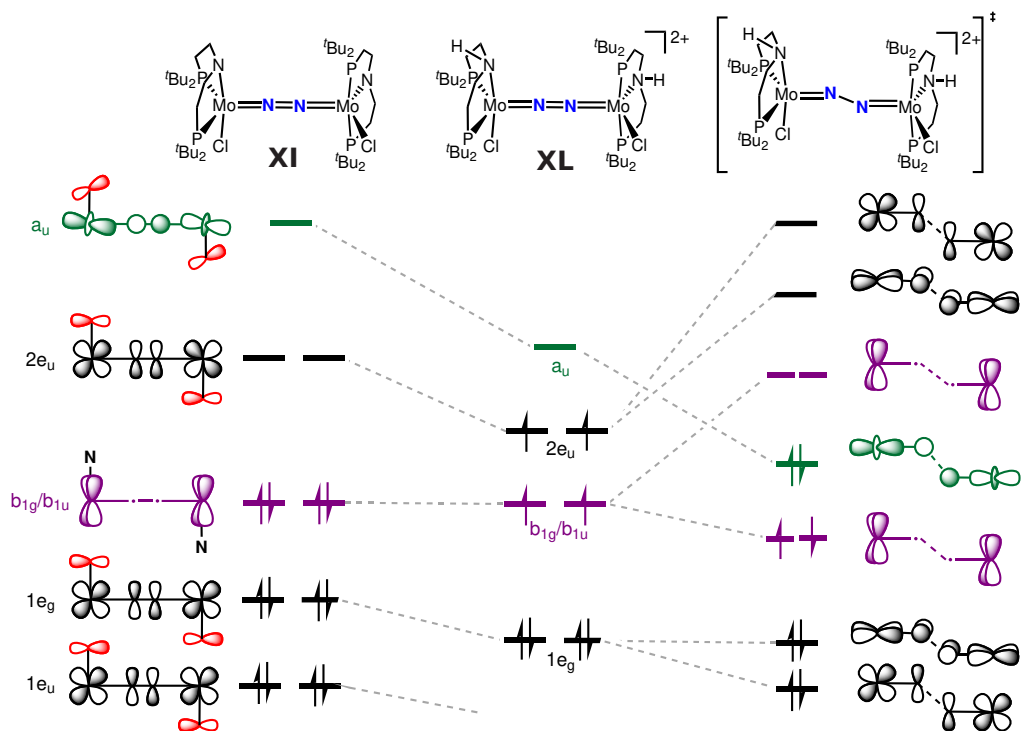

A similar behavior was demonstrated experimentally by *Schneider* for the already mentioned [(N<sub>2</sub>)<sub>2</sub>{MoCl(PNP)}<sub>2</sub>](**XI**). As already discussed, **XI** features a  $\pi^8\delta^4$ -configuration and is thermally stable with respect to N<sub>2</sub>-cleavage similar to *Cummins'* dicationic **III**. Counterintuitively, protonation of **XI** results in N<sub>2</sub>-cleavage and formation of the corresponding Mo(V)-nitride, [Mo(N)Cl(<sup>H</sup>PNP)]<sup>+</sup> (**XXXVIII**). It was shown that the first as well as the second protonation both occur on the amide of the pincer-ligand(s). While the monoprotonated intermediate **XXXIX** is diamagnetic, double protonation leads to a quintet ground state for **XL**, as expected for a  $\pi^{10}\delta^2$ -configuration.<sup>70</sup>

## 1.2 N<sub>2</sub>-Functionalization

Scheme 25: Proposed mechanism of proton induced N<sub>2</sub>-splitting.<sup>70</sup>

Computational analysis of the reaction revealed an interaction of the amide-p-orbital with the {MoNNMo}-core (Scheme 26, *left*). Therefore the 2e<sub>u</sub>-orbital is destabilized, which leads to a low-spin  $\pi^8\delta^4$ -configuration due to the large energy gap between the b<sub>1u</sub> and b<sub>2g</sub>- $\delta$ -orbitals to the 2e<sub>u</sub>-orbitals. Additionally, the energy of the a<sub>u</sub> is also enhanced, which results in a high kinetic barrier ( $\Delta G_{\text{calc}}^\ddagger = 37 \text{ kcal}\cdot\text{mol}^{-1}$ ) for N<sub>2</sub>-cleavage.<sup>70</sup>

Scheme 26: Qualitative frontier molecular orbitals diagram for **XI** (*left*), **XL** (*middle*) and the calculated zig-zag-transition state from **XL** to **XXXVIII** (*right*).<sup>70</sup>

## 1.2 N<sub>2</sub>-Functionalization

Upon double protonation both amide-p-orbitals are engaged in covalent bonding to H and do not interact with the {MoNNMo}-core anymore (Scheme 26, *middle*). Accordingly, the 2e<sub>u</sub>-orbitals drop in energy and become populated to give a π<sup>10</sup>δ<sup>2</sup>-configuration, in line with the observed quintet-ground state for **XL**. Furthermore, the energy of the a<sub>u</sub>-orbital is also diminished, which results in a reduced kinetic barrier for N<sub>2</sub>-cleavage ( $\Delta G_{\text{calc}}^{\ddagger} = 21 \text{ kcal}\cdot\text{mol}^{-1}$ ) in good agreement with the experimentally derived values ( $\Delta H_{\text{exp}}^{\ddagger} = 17.8 \text{ kcal}\cdot\text{mol}^{-1}$ ;  $\Delta H_{\text{calc}}^{\ddagger} = 19 \text{ kcal}\cdot\text{mol}^{-1}$ ).<sup>70</sup>

Another approach for N<sub>2</sub>-cleavage was presented by *Masuda* (Scheme 27). Instead of reducing a Mo-precursor in a relatively high oxidation state, the group utilized zero-valent *trans*-[Mo(N<sub>2</sub>)<sub>2</sub>(depe)<sub>2</sub>] (depe = Et<sub>2</sub>PCH<sub>2</sub>CH<sub>2</sub>PEt<sub>2</sub>, **XLla**) for N<sub>2</sub>-cleavage. One electron oxidation of **XLla** gives the respective nitride, [Mo(N)(depe)<sub>2</sub>]<sup>+</sup> (**XLlb**), via formation of intermediate [(N<sub>2</sub>){Mo(depe)<sub>2</sub>}<sub>2</sub>]<sup>2+</sup> (**XLlc**) with a π<sup>10</sup>δ<sup>4</sup>-configuration.<sup>20</sup>

Scheme 27: Oxidative N<sub>2</sub>-cleavage as presented by *Masuda*.<sup>20</sup>

Overall, all these examples imply the requirement of ten electrons within the {MNNM}-π-manifold for NN-bond cleavage in such N<sub>2</sub>-bridged complexes to form the respective nitride-complexes. The thermodynamic and kinetic parameters of N<sub>2</sub>-splitting can be tuned by addition of a ligand *trans* to the N<sub>2</sub>-bridge, which raises the kinetic barrier for N<sub>2</sub>-cleavage by increasing the energy gap between the 2e<sub>u</sub>- and the a<sub>u</sub>-orbital.

For instance, octahedrally coordinated [(N<sub>2</sub>){ReCl<sub>2</sub>(<sup>H</sup>PNP<sup>iPr</sup>)<sub>2</sub>}] (**XIII**) features the same electron count and degree of activation as **XII** (Scheme 28). Nevertheless, **XIII** is thermally stable and provides a high kinetic barrier for N<sub>2</sub>-cleavage ( $\Delta G_{\text{calc}}^{\ddagger} = 41.8 \text{ kcal}\cdot\text{mol}^{-1}$ ), which is in contrast to the kinetic barrier for N<sub>2</sub>-cleavage for **XII** ( $\Delta G_{\text{calc}}^{\ddagger} = 20.2 \text{ kcal}\cdot\text{mol}^{-1}$ ).<sup>15,36,71</sup>

Besides this kinetic influence, the thermodynamic driving force for N<sub>2</sub>-cleavage is also affected. While splitting of **XII** into the respective five-coordinate [Re(N)Cl(PNP)] (**XXXVII**) is strongly exergonic ( $\Delta G_{298\text{K}}^{\circ} = -40.3 \text{ kcal}\cdot\text{mol}^{-1}$ ), splitting of **XIII** into the respective six-coordinate *trans*-[Re(N)Cl<sub>2</sub>(<sup>H</sup>PNP<sup>iPr</sup>)] (**XLIIa**) is calculated to be almost thermoneutral ( $\Delta G_{298\text{K}}^{\circ} = 2.2 \text{ kcal}\cdot\text{mol}^{-1}$ ). Additional driving force is added by isomerization into the *cis*-dichloro nitride **XLIIb**.

## 1.2 N<sub>2</sub>-Functionalization

This difference can be rationalized by the strong  $\sigma$ - and  $\pi$ -donating properties of the nitride moiety, which compete with a ligand in *trans*-position. Accordingly, the lower thermodynamic driving force for **XIII** can be explained by a destabilization of **XLII**.<sup>15,36,71</sup>

Scheme 28: Calculated energies for N<sub>2</sub>-cleavage for **XII** (black) and **XIII** (green) via a zig-zag-transition state.<sup>15,36,71</sup>

Even though, N<sub>2</sub>-splitting has a high kinetic barrier and only a low thermodynamic driving force, **XIII** can be transformed into **XLIIb** upon photolysis. In contrast to **XXXVII**, which is largely overstabilized, splitting into **XLIIb** is almost thermoneutral. As a consequence **XLIIb** can be functionalized with much weaker electrophiles compared to **XXXVII**.<sup>71</sup> This is one of the benefits of photolytical N<sub>2</sub>-cleavage, which will be discussed in the next chapter.

1.2.3 Photolytic N<sub>2</sub>-cleavage

Although first suggested by *Fischler* and *von Gustorf* in 1975,<sup>135</sup> the photolytic cleavage of N<sub>2</sub> is still by far less well established than the thermal N<sub>2</sub>-cleavage, which is reflected by the low number of compounds capable for photolytic N<sub>2</sub>-splitting. The first example was published in 2001 by the group of *Floriani* using a mesityl-ligated N<sub>2</sub>-bridged dimolybdenum-complex, [(N<sub>2</sub>){Mo(Mes)<sub>3</sub>}<sub>2</sub>] (Mes = 2,4,6-Me<sub>3</sub>-C<sub>6</sub>H<sub>2</sub>, **XXXIIa**). Even though, **XXXIIa** features a π<sup>10</sup>-configuration in a S<sub>6</sub>-symmetry and is therefore isostructural and isoelectronic to *Cummins' I*, thermal N<sub>2</sub>-cleavage has not been reported. These differences were assigned to the weaker σ- and π-donor properties of the mesityl ligands compared to the amido ligands used by *Cummins* (see chapter 1.2.2). Nevertheless, irradiation of **XXXIIa** with UV-light (λ = 365 nm) results in formation of nitride bridged [(N){Mo(Mes)<sub>3</sub>}<sub>2</sub>] (**XXXIIb**).<sup>133</sup> The group of *Floriani* postulated a mechanism in which the initially formed terminal nitride [Mo(N)(Mes)<sub>3</sub>] (**XXXIIc**) acts as a Lewis base which binds **XXXIIa** to give tetranuclear **XXXIIId**. Loss of the N<sub>2</sub>-bridge yields the final product **XXXIIb**, which was also observed upon reaction of independently prepared **XXXIIc** with **XXXIIa** (Scheme 29).<sup>133</sup>

Scheme 29: Proposed mechanism for the formation of **XXXIIb** upon irradiation of **XXXIIa**.<sup>133</sup>

An alternative mechanism was later proposed by *Cummins* (Scheme 30). Upon irradiation of **I** at low temperatures, in order to prevent thermal N<sub>2</sub>-splitting, an equimolar mixture of [Mo(N(R)Ar)<sub>3</sub>] (**XXX**) and [Mo(N)(N(R)Ar)<sub>3</sub>] (**XXXI**) was obtained, hinting towards competitive N<sub>2</sub>-splitting and -extrusion pathways. Due to the steric bulk of the amido-ligands, the reaction of **XXX** and **XXXI** to give a nitride-bridged species is circumvented in *Cummins' case*, while the mesityl-ligands used by *Floriani* provide enough space for the formation of nitride-bridged **XXXIIb**.<sup>61</sup>

## 1.2 N<sub>2</sub>-Functionalization

Scheme 30: Irradiation of **I** or **XXXIIa** leads to competitive N-N- and M-N<sub>2</sub>-cleavage and in case of **XXXIIa** to recombination of **XXXIIc** and **XXXIIe** to give nitride bridged **XXXIIb**.<sup>61</sup>

The photoreactivity of **I** was examined by UVvis pump-probe spectroscopy in combination with extensive DFT-calculations by the groups of *Cummins* and *Blank*. Based on the used truncated DFT model with simple NH<sub>2</sub>-ligands, the strong electronic absorption at 534 nm found for **I** was assigned to an excitation from the triplet ground state into the second excited triplet state ( $e_g^4 e_u^2 \rightarrow e_g^3 e_u^3$ ). Such a transition implies charge transfer from a more metal based Mo-N<sub>2</sub>-bonding and N-N-antibonding orbital ( $\pi$ - $\pi^*$ - $\pi$ ) into an N<sub>2</sub>-centered orbital with Mo-N<sub>2</sub>-antibonding and N-N-bonding character ( $\pi^*$ - $\pi$ - $\pi^*$ ) within the {MoNNMo}-core. The excited state is very short-lived and undergoes internal conversion back to the hot ground state within 300-800 fs. The small overall quantum yield ( $\Phi = 5\%$ ) was used as an indicator for competitive unproductive vibrational cooling and productive Mo-N<sub>2</sub>- or N-N-cleavage. The almost equally distributed amounts of Mo-N<sub>2</sub>- and N-N-splitting products contrast their different thermal barriers, which should favor cleavage of the Mo-N<sub>2</sub>-bond.<sup>132</sup> This observation was rationalized by a nonthermal vibrational energy distribution created by the internal conversion process due to coupling with {MoNNMo}-bending modes, which should add some bias to the NN-dissociation path. Overall, the photolytical cleavage of **I** was portrait as a reaction from a vibrationally hot ground state with a non-statistical energy distribution, which results in different selectivities for Mo-N<sub>2</sub> and N-N-cleavage compared to the thermal pathway.<sup>136</sup>

By now, **I** is the only system capable for photolytic N<sub>2</sub>-cleavage whose photochemical and -physical properties have been experimentally probed. Another experimental study on the photophysics of an N<sub>2</sub>-bridged dinuclear complex was reported by the groups of *Chirik* and *Scholes*.<sup>137</sup> Although the used  $[(N_2)\{Mo(Tpy^{Ph})(PMe_2Ph)_2\}]^{2+}$  (**XVII**<sup>2+</sup>; Tpy<sup>Ph</sup>=4'-Ph-2,2',6,6'2"-terpyridine, Figure 6) does not show any photoreactivity, the study revealed some fundamental aspects and guidelines for effective photolytic N<sub>2</sub>-cleavage. All probed excitations with wavelengths between 440 and 1150 nm showed strong MLCT character by populating a <sup>1</sup>MLCT-state with strong  $\pi^*$ -Tpy<sup>Ph</sup>-ligand character within 100 fs. Relaxation either *via* internal conversion or inter system crossing occurs within 2-3 ps. The inter system crossing from the ex-

## 1.2 N<sub>2</sub>-Functionalization

cited <sup>1</sup>MLCT-state into the <sup>3</sup>MLCT-state results in migration of electron density from the Typ<sup>Ph</sup>-ligand into the bridging N<sub>2</sub>-unit, which could increase the nucleophilicity of the N<sub>2</sub>-bridge and thereby increase its reactivity. However, relaxation into the ground state, either *via* direct decay (10-15 ps) or *via* indirect decay through an intermediate high-energy metal state (23-26 ps), occurs too fast for bimolecular reactivity. This drawback could potentially be overcome by increasing the excited state lifetime upon usage of a more electron deficient terpyridine-ligand or *via* subsequent intramolecular trapping of the excited state, as also suggested by *Reiher* and *Sellmann*.<sup>138</sup> Overall, this example demonstrates how supporting ligands can act as strong light harvesters that transfer energized electron density to the {MNNM}-core and thereby potentially increase its reactivity.<sup>137</sup> More recent studies of the system had shown, that this energy transfer from the chromophore to the N<sub>2</sub>-bridge gains efficiency due to Fermi-resonance coupling of the vibrational modes of the Mo(Typ<sup>Ph</sup>)-moiety and the {MoNNMo}-core.<sup>139</sup>

Competitive M-N<sub>2</sub>- and N-N-cleavage was also observed for another class of compounds capable for photolytical N<sub>2</sub>-cleavage. Irradiation of *Sita's* already mentioned, thermally stable N<sub>2</sub>-bridged η<sup>5</sup>-cyclopentadienyl/η<sup>2</sup>-amidinate complexes (M = Mo **XVIg**, W **XVIh**) yields bis-nitride bridged [(N)<sub>2</sub>(MCp\*am)<sub>2</sub>] (M = Mo **XLIIia**, W **XLIIib**, Scheme 31). In case of the Mo-compound, **XVIg**, the formation of mononitride [(N)(MoCp\*am)<sub>2</sub>] (**XLIVa**) strongly hints towards competitive M-N<sub>2</sub> and N-N-bond breakage, reminiscent to the examples by *Floriani* and *Cummins*.<sup>140</sup> Upon variation of the substituents on the amidinate-ligand (am\* = [N(Et)C(Ph)N(Et)]<sup>-</sup>, **XLV**) thermal N<sub>2</sub>-cleavage into the bis-nitrido-complexes [(N)<sub>2</sub>(MCp\*am\*)<sub>2</sub>] (M = Mo **XLVla**, W **XLVlb**) could be achieved, showcasing how relatively small changes on the ligand-framework can have a large impact on the reactivity of such N<sub>2</sub>-bridged compounds.<sup>85</sup>

Scheme 31: Photolytical (R<sup>1</sup> = *i*Pr; R<sup>2</sup> = Me) and thermal (R<sup>1</sup> = Et; R<sup>2</sup> = Ph) N<sub>2</sub>-cleavage of *Sita's* η<sup>5</sup>-cyclopentadienyl/η<sup>2</sup>-amidinate complexes (M = Mo **XVIg**, **XLVa** and W **XVIh**, **XLV**).<sup>85,140</sup>

## 1.2 N<sub>2</sub>-Functionalization

Using structurally related [(N<sub>2</sub>){MoCp\*(depf)}<sub>2</sub>] (depf = 1,1'-bisdiethylphosphino-ferrocene, **XLVIIa**) photolytical cleavage into a terminal nitride [Mo(N)Cp\*(depf)] (**XLVIII**) was demonstrated by the group of *Nishibayashi* (Scheme 32). Remarkably, the splitting reaction could be reversed upon one electron oxidation of **XLVIII** giving dicationic [(N<sub>2</sub>){MoCp\*(depf)}<sub>2</sub>]<sup>2+</sup> (**XLVIIb**) via nitride coupling. **XLVIIb** can be reduced again to give monocationic **XLVIIc** and neutral **XLVIIa** thereby closing the synthetic cycle.<sup>16</sup>

Scheme 32: Photolytical splitting of **XLVIIa** gives terminal nitride **XLVIII**, whose oxidation yields in **XLVIIb** via nitride coupling.<sup>16</sup>

Another example, which was later computationally studied by *González and Krewald*, was presented by *Kunkely and Vogler* (Scheme 33).<sup>141</sup> Irradiation of the mixed valent, valence localized Os<sup>II</sup>/Os<sup>III</sup>-N<sub>2</sub>-bridged complex [(NH<sub>3</sub>)<sub>5</sub>Os<sup>II</sup>](N<sub>2</sub>)(Os<sup>III</sup>(NH<sub>3</sub>)<sub>5</sub>)<sup>5+</sup> (**XLIXa**) yields the respective Os<sup>V</sup>- and Os<sup>VI</sup>-nitride-complexes, [Os<sup>V</sup>(N)(NH<sub>3</sub>)<sub>5</sub>]<sup>2+</sup> (**La**) and [Os<sup>VI</sup>(N)(NH<sub>3</sub>)<sub>5</sub>]<sup>3+</sup> (**Lb**). The strong *trans*-influence of the nitride-ligand causes NH<sub>3</sub>-liberation. Additionally, the Os(V)-nitride (**La**) gets subsequently oxidized to stabilize the Os≡N-bond and form another equivalent of [Os<sup>VI</sup>(N)(NH<sub>3</sub>)<sub>4</sub>]<sup>3+</sup> (**Lc**, see also Scheme 40). Notably, direct cleavage into **Lb** upon irradiation of the corresponding Os<sup>III</sup>/Os<sup>III</sup> complex, [(NH<sub>3</sub>)<sub>5</sub>Os<sup>III</sup>](N<sub>2</sub>)(Os<sup>III</sup>(NH<sub>3</sub>)<sub>5</sub>)<sup>6+</sup> (**XLIXb**), was unsuccessful, since the latter liberates N<sub>2</sub> upon irradiation or at temperatures above 5 °C.<sup>141</sup>

## 1.2 N<sub>2</sub>-Functionalization

Scheme 33: Irradiation of **XLIXa** yields in **La** and **Lb**, which subsequently react further to give two equivalents of **Lc**.<sup>142</sup>

*González* and *Krewald* calculated the effect of NN-bond elongation on the relative MO-energies of **XLIXa** to finally give **La** and **Lb** (Scheme 34). Elongation of the NN-bond decreases the overlap of the two N-p<sub>z</sub>-orbitals leading to weaker separation of the N-N  $\sigma/\sigma^*$ -levels and a stabilization of the  $\sigma-\sigma^*$ - $\sigma$ -orbital. Once both nitrogen atoms are far enough separated, the  $\sigma-\sigma^*$ - $\sigma$ -orbital becomes degenerate with the  $\pi^*-\pi^*$ -orbital. As a result the electronic configuration as well as the NN-bond strength change since electrons are transferred from the former HOMO ( $\pi^*-\pi-\pi^*$ ), with NN-bonding and Os-N<sub>2</sub> antibonding-character, into an orbital with NN-antibonding and Os-N<sub>2</sub>-bonding character ( $\sigma-\sigma^*-\sigma$ ). Full cleavage into the two monomers, **La** and **Lb**, goes along with degeneration of the former  $\sigma-\sigma^*$ - $\sigma$ - with the former  $\sigma-\sigma-\sigma$ -orbital.<sup>142,143</sup>

Taking these considerations into account, two possible scenarios for photolytical N<sub>2</sub>-cleavage have been postulated. One possibility is the electronic excitation into an excited state with an distorted M-N-N-M core, which lowers the energy of the  $\sigma-\sigma^*$ - $\sigma$ -orbital making it accessible for population and thereby lowering the kinetic barrier for N<sub>2</sub>-cleavage. Another possibility would be the direct electronic excitation into the  $\sigma-\sigma^*$ - $\sigma$ -orbital leading to a large decrease of the NN-bond strength. This effect would be maximized if the excited electron originates from an MN- $\pi^*$ -orbital, since in this way the MN-bond-order would be increased while the NN-bond-order would be decreased.<sup>142,143</sup>

## 1.2 N<sub>2</sub>-Functionalization

Scheme 34: Molecular orbital scheme for the cleavage of **XLIXa** into **La** and **Lb** upon elongation of the NN-bond distance.<sup>142</sup>

These proposed scenarios can also be applied to the already discussed photoactive systems by *Sita* (**XVIg**, **XVIh**), *Nishibayashi* (**XLVIIa**) and *Schneider* (**XIII**), although their photochemical and photophysical properties are not fully understood yet. For instance, computational analysis by *Krewald* of photoactive **XVIg** revealed an excitation with LMCT-character from the bridging N<sub>2</sub> ligand to the Mo-ions.<sup>144</sup> Such a transition should weaken the NN-bond and thereby increase the flexibility of the {MoNNMo}-core. Notably, such a transition is not predicted for the photoinactive analogue **XLVa**. Further comparison between both systems, **XVIg** and **XLVa**, also unveiled several LMCT transitions from both amidinate and Cp\*, which were only present in photoactive **XVIg** and could induce ligand dissociation as initial step for isomerization into **XLIIIa** as it was also proposed by *Sita*.<sup>85,144,145</sup>

TD-DFT calculations of *Nishibayashi's* structurally related **XLVIIa** imply that the active transition also leads to a decrease of electron density between both nitrogen atoms resulting in a more flexible Mo-N-N-Mo unit.<sup>16</sup>

The active transitions within *Schneider's* **XIII** were attributed to have mainly ( $\delta/\delta^*$ )  $\rightarrow$  ( $\pi^* - \pi^* - \pi^*$ )-character, which could lead to distortions of the {ReNNRe}-core possibly promoting N<sub>2</sub>-cleavage *via* a *zig-zag*-transition state.<sup>71</sup>

## 1.2 N<sub>2</sub>-Functionalization

Another example, structurally related to already discussed **XIII**, was recently reported by the group of *Miller*. Reduction of [ReCl<sub>3</sub>(PONOP)] (**LI**; PONOP = 2,6-(*i*Pr<sub>2</sub>PO)<sub>2</sub>-NC<sub>5</sub>H<sub>3</sub>) in presence of N<sub>2</sub> forms the N<sub>2</sub>-bridged dinuclear *trans, trans*-**LIIa**, which is thermally stable with respect to N<sub>2</sub>-cleavage but isomerizes into the thermodynamically more favored *cis, trans*-**LIIb** and *cis, cis*-**LIIc** above 130 °C (Scheme 35). Each isomer transforms into *cis*-[Re(N)Cl<sub>2</sub>(PONOP)] (**LIIIa**) upon irradiation (λ = 405 nm), although with very different quantum efficiencies and yields, with **LIIc** being most effective (Table 5).<sup>21</sup>

Scheme 35: Formation of the N<sub>2</sub>-bridged dinuclear Re-PONOP-species **LII** and their interconversion into **LIIIa** upon photolysis.<sup>21</sup>

The incapability for thermal N<sub>2</sub>-cleavage for all three dinuclear species was rationalized by a high kinetic barrier ( $\Delta G^\ddagger = 51.3\text{-}53.2 \text{ kcal}\cdot\text{mol}^{-1}$ ), furthermore cleavage of the NN-bond into the respective *cis/trans*-[Re(N)Cl<sub>2</sub>(PONOP)] (**LIIIa/LIIb**) was calculated to be endergonic ( $\Delta G^\circ = 10.5\text{-}13.9 \text{ kcal}\cdot\text{mol}^{-1}$ ). Isomerization of *trans*-**LIIb** into *cis*-**LIIIa** was calculated to be exergonic ( $\Delta G^\circ = -6.4 \text{ kcal}\cdot\text{mol}^{-1}$ ) in line with the exclusive formation of **LIIIa** upon photolysis. However, the high barrier for N<sub>2</sub>-cleavage circumvents nitride coupling of **LIIIa** to N<sub>2</sub>-bridged **LIIc**, which was observed neither thermally nor photolytically.<sup>21</sup>

Table 5: Photolysis (λ = 405 nm) of different mixtures of **LIIa**, **LIIb** and **LIIc** gives different quantum yields (Φ, obtained after 2 h) and yields of **LIIIa**.<sup>21</sup>

<b>LIIa</b>	<b>LIIb</b>	<b>LIIc</b>	Φ (after 2 h)	Yield	time
8	1	0	0.003	<3%	9 d
0	7	1	0.06	24%	7.5 h
0	1	1	0.11	47%	7 h

## 1.2 N<sub>2</sub>-Functionalization

---

Overall, the system of *Miller* represents another good example how photolysis enables N<sub>2</sub>-splitting over a high kinetic barrier and without a thermodynamic driving force. Such thermoneutral (or even endergonic) reactions hold the promise of forming less stabilized and therefore easier to functionalize N<sub>2</sub>-derived nitrides.<sup>143</sup> For example, requires thermally obtained [Re(N)Cl(PNP)] (**XXXVII**) strong electrophiles, like alkyl-triflates, for functionalizations of the nitride moiety *via* C-N-coupling.<sup>15,146</sup> In contrast, [Re(N)Cl<sub>2</sub>(<sup>H</sup>PNP<sup>iPr</sup>)] (**XLII**), generated photolytically, can be functionalized with milder electrophiles, such as benzoylchlorides, to give benzamide.<sup>71</sup> The functionalization of N<sub>2</sub>-derived nitrides will be discussed in the next chapter.

### 1.3 Nitride-Functionalization

The cleavage of  $N_2$  typically results in the formation of a transition metal nitride. However, such nitrides are mostly not prepared *via*  $N_2$ -scission and represent a long known class of compounds, which can be synthesized on various different routes.<sup>131</sup> The first report for a transition metal nitride dates back to the synthesis of  $[OsO_3N]^-$  in 1847.<sup>147</sup> Since then the chemistry of transition metal nitrides has evolved and was covered in many review articles.<sup>45,131,148-156</sup>

This chapter will focus on more general bonding considerations and the resulting reactivity of transition metal nitrides. Afterwards, the reactivity of  $N_2$ -derived nitrides, with focus on C-N-coupling reactions, will be discussed.

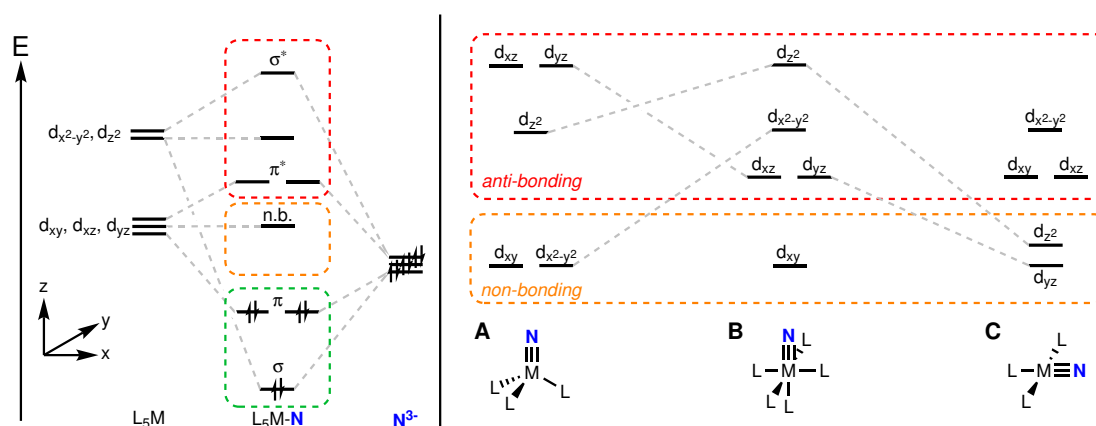

#### 1.3.1 Bonding of terminal transition metal nitrides

The metal-nitride bond is considered as a triple bond consisting of one  $\sigma$ - and two  $\pi$ -bonds, in which the nitride ligand acts as both a strong  $\sigma$ - and  $\pi$ -donor. Although, this description as well as the typical consideration as  $N^{3-}$  imply a rather nucleophilic character, the high covalent character of the  $M\equiv N$ -bond can also lead to electrophilic behavior, especially for late transition metals.<sup>131</sup>

To understand the stability and reactivity of such metal-nitride complexes it is important to understand their electronic structure. *Gray* and *Ballhausen* developed a bonding picture for octahedral  $[VO(OH_2)_5]^{2+}$ , which can be adopted for octahedral nitride complexes and translated into other geometries.<sup>157</sup> Considering the  $M\equiv N$ -bond to be oriented along the z-axis, linear combination of the metal  $d_{z^2}$ - with the nitrogen  $p_z$ -orbital results in  $\sigma$ -bond formation, while combination of the  $d_{xz}$ - and  $d_{yz}$ -orbitals with the  $p_x$ - and  $p_y$ -N-orbitals, respectively, results in  $\pi$ -interactions. Due to the lack of N-orbitals with suitable symmetry, the  $d_{xy}$ - and  $d_{x^2-y^2}$ -orbitals remain non-bonding with respect to the  $M\equiv N$ -bond. The nitride-ligand (formally considered as  $N^{3-}$ ) adds six electrons to this scheme, which results in full occupation of all bonding-orbitals and a bond order of three (Scheme 36, *left*). The remaining orbitals can be populated with former metal d-electrons. Accordingly, the stability and reactivity of the metal-nitride bond relies on the number of remaining d-electrons. In case of a  $d^0$ -configuration only orbitals with MN-bonding character are populated, while upon addition of one or two more electrons the former  $d_{xy}$ -orbital with non-bonding character gets occupied. A higher number of electrons leads to population of MN-antibonding orbitals and weakening of the  $M\equiv N$ -bond. Furthermore, occupation of the  $d_{x^2-y^2}$ -orbital reduces the bond-order to the remaining supporting ligands. Hence, octahedrally coordinated metal-nitrido-complexes require a low number of d-electrons to be stable in line with the low number of late transition metal nitrides in this coordination mode.<sup>155,158</sup> Additionally, the strong  $\sigma$ - and  $\pi$ -donor properties of the nitride ligand have a strong *trans*-influence, which often prevent binding of a ligand in *trans*-position and foster the formation of square-pyramidal complexes with the nitrido-ligand on the apical position.<sup>131</sup>

### 1.3 Nitride-Functionalization

Scheme 36: *left*: Qualitative orbital interactions within octahedrally coordinated L<sub>5</sub>MN. *right*: Qualitative frontier molecular orbital scheme for metal nitrido complexes in tetrahedral, octahedral and square-planar coordination geometries.<sup>45,131,157,159</sup>

Higher d-electron counts can be stabilized within different coordination geometries. Within a tetrahedral geometry the d<sub>x<sup>2</sup>-y<sup>2</sup></sub>-orbital becomes overall non-bonding and drops in energy, degenerate with the d<sub>yz</sub>-orbital. Since both of these orbitals have an overall non-bonding character, a d-electron count up to four can be stabilized. This was first shown by *Peters*<sup>45</sup> for a pseudo-tetrahedral Fe(IV)-nitride, [Fe(N)(P<sup>i</sup>Pr<sub>3</sub>BPh)] (**LIV**, P<sup>i</sup>Pr<sub>3</sub>BPh = [PhB(CH<sub>2</sub>P<sup>i</sup>Pr<sub>2</sub>)<sub>3</sub>]<sup>-</sup>) and later independently by *Meyer*<sup>160</sup> and *Smith*<sup>161</sup> with structurally related Fe(IV)-nitrides both supported by tripodal carbene-ligands. All three compounds exhibit a singlet ground state in agreement with the proposed MO-scheme shown in Scheme 36 (*right*, A), which was further corroborated by DFT-calculations.<sup>45,160,161</sup>

Square-planar coordination geometries can also stabilize higher d-electron counts. Considering the M≡N-bond to be oriented along the x-axis, the d<sub>z<sup>2</sup></sub>-orbital drops in energy and becomes non-bonding, which should lead to the MO-diagram shown in Scheme 36 (*right*, C).<sup>159</sup> The first example for a square-planar d<sup>4</sup>-nitride, [Ru(N)(PNP<sup>Si</sup>)] (**LV**, PNP<sup>Si</sup> = [N(SiMe<sub>2</sub>CH<sub>2</sub>P<sup>t</sup>Bu<sub>2</sub>)<sub>2</sub>]<sup>-</sup>), was presented by the group of *Caulton*.<sup>162</sup> Notably, upon usage of this coordination geometry, the groups of *Burger* and *Schneider* were also able to stabilize the d<sup>5</sup>-configured nitrides, [Ir(N)(PDI)] (**LVI**; PDI = pyridinediimino) and [M(N)(PNP<sup>''</sup>)] (M = Rh (**LVII**), Ir (**LVIII**); PNP<sup>''</sup> = [N(CHCHP<sup>t</sup>Bu<sub>2</sub>)<sub>2</sub>]<sup>-</sup>), respectively (Figure 10).<sup>46-48,163</sup>

### 1.3 Nitride-Functionalization

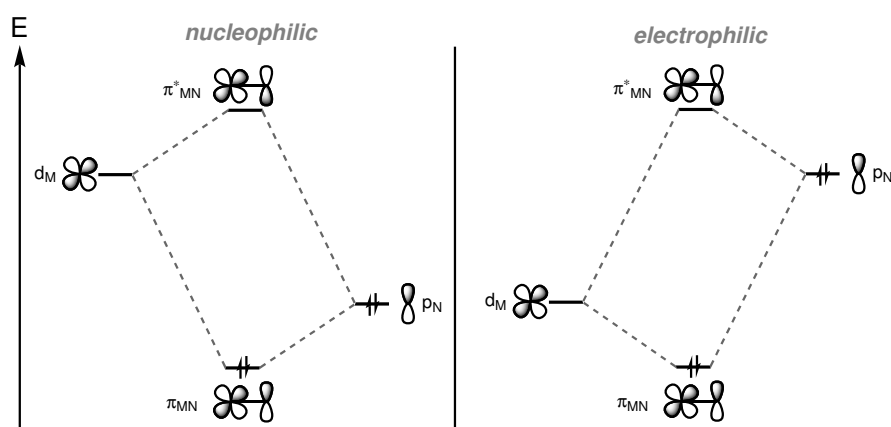

Figure 10: Pincer-supported, square-planar nitrido-complexes reported by *Caulton*<sup>162</sup> (left), *Burger*<sup>46</sup> (middle, R = di-isopropylphenyl) and *Schneider*<sup>47,48</sup> (right).

While these considerations give some insights into the stability of the  $M\equiv N$ -bond, the philicity of the nitride ligand itself depends on the relative energies of the metal-d- and nitrogen-p-orbitals forming one of the two  $\pi$ -bonds. Upon comparison two scenarios evolve: In one case, when the metal d-orbitals are energetically higher than the nitrogen p-orbitals, the two  $\pi$ -bonding electrons are mainly nitrogen-centered, making the nitride nucleophilic (Scheme 37, left). In the opposite scenario, when the metal d-orbitals are energetically below the nitrogen p-orbitals, the bonding  $\pi$ -orbital has mainly metal-character and the corresponding antibonding  $\pi^*$ -orbital is mainly nitrogen-centered resulting in a more electrophilic nitride (Scheme 37, right).<sup>131,151</sup>

Scheme 37: Simplified molecular orbital schemes for the  $\pi$ -interaction within the metal-nitride-bond, either leading to a nucleophilic or electrophilic character of the nitride-ligand.<sup>131</sup>

Accordingly, the electrophilic character of the nitrido-ligand should increase moving right along the periodic table. This trend was also determined computationally *via* population analysis for a series of  $[M(N)(\text{salen})]$  and  $[M(N)\text{Cl}_4]^{2+}$  complexes ( $M = \text{V}, \text{Cr}, \text{Mn}, \text{Fe}$ ; salen = *N,N'*-bis(salicylidene)ethyldiamine dianion) using DFT, which showed a decreasing negative charge at the nitride ligand moving right along the periodic table.<sup>164</sup>

### 1.3 Nitride-Functionalization

However, the reactivity of the nitride does not only rely on the metal and electron count as the supporting ligands can also model its reactivity, as shown by the group of Mayer using a Tp-supported Os-nitride complex,  $[\text{Os}(\text{N})\text{R}_2(\text{Tp})]$  **LIX**; Tp = trispyrazolylborate).<sup>165–167</sup> While the bis-chloro complex,  $[\text{Os}(\text{N})\text{Cl}_2(\text{Tp})]$  (**LIXa**), reacts fast with *Grignard*-reagents, such as PhMgCl, under the formation of the respective imido-complex, the bis-phenyl complex,  $[\text{Os}(\text{N})\text{Ph}_2(\text{Tp})]$  (**LIXb**), barely reacts with PhMgCl, implying different reactivity of the nitride-moiety.<sup>165,166</sup> Different reactivity was also found upon addition of triarylboranes (Scheme 38). Phenyl-ligated **LIXb** reacts as a nucleophile and forms N-B adducts,  $[\text{Os}(\text{NB}(\text{C}_6\text{F}_5)_3)\text{Cl}_2(\text{Tp})]$  (**LX**). In contrast, chloro-ligated **LIXa** inserts as an electrophile into the B-Ar-bond and forms the respective borylanilido compound (**LXI**).<sup>166,167</sup> The different reactivity was rationalized computationally. The nearly degenerate LUMO and LUMO+1 of **LIXa** are low lying, M-N  $\pi$ -antibonding and mainly nitrogen centered, in line with the observed electrophilic behavior. Upon exchange of Cl vs. more  $\sigma$ -donating Ph, both orbitals rise in energy, which explains the reduced electrophilicity of **LIXb** compared to **LIXa**.<sup>166</sup>

Scheme 38: Ligand influence on the nucleophilicity of an Tp-supported Os-nitride.<sup>166,167</sup>

All in all, these considerations as well as the high covalent character of the  $\text{M}\equiv\text{N}$ -bond demonstrate that the typical description of the nitride ligand as  $\text{N}^{3-}$  can be misleading. A very illustrative example was published by the group of Wiegardt. Comparison of the structural parameters of  $[\text{M}(\text{N})(\text{CN})_4(\text{OH}_2)]^{2-}$  ( $\text{M} = \text{Re}$  (**LXIIa**),  $\text{Mn}$  (**LXIIb**)) with the corresponding nitrosyl complexes  $[\text{M}(\text{NO})(\text{CN})_4(\text{OH}_2)]^{2-}$  ( $\text{M} = \text{Re}$  (**LXIIIa**),  $\text{Mn}$  (**LXIIIb**)) showed almost no difference in the M-CN distances, even though, upon considering the nitride-ligand as trianionic and the nitrosyl-ligand as monocationic, the oxidation state of the metal has changed from +V to +I.<sup>168</sup>

Therefore, a different notation,  $\{\text{M}-\text{N}\}^n$ , similar to the *Enemark-Feltham* notation<sup>169</sup> for  $\{\text{M}-\text{NO}\}$ -complexes, was proposed. Within this  $\{\text{M}-\text{N}\}^n$ -notation,  $n$  represents the number of d-electrons within the  $\text{M}\equiv\text{N}$ -fragment, considering the nitrido-ligand as a trianionic ligand. In this way, the actual distribution of the electrons within the  $\text{M}\equiv\text{N}$ -

bond remains undefined. Additionally,  $n$  can be correlated to the MO-schemes shown in Scheme 36 and can give some insights about the stability of the metal-nitride-bond.<sup>168</sup>

### 1.3.2 Reactivity of $N_2$ -derived nitrides

Applying these bonding considerations to the  $N_2$ -generated terminal nitrides presented in the previous chapters it can be seen, that most of the pincer-supported nitrides as well as *Masuda's*  $[Mo(N)(depe)_2]^+$  (**XLIIb**) exhibit  $d^2$ -configurations. Accordingly, the MN-non-bonding HOMO of these nitrides is fully occupied and further reduction should lead to weakening of the  $M\equiv N$ -bond. One exception is *Schneider's*  $[Mo(N)Cl(^H)PNP]^+$  (**XXXVIII**), which features a  $d^1$ -configuration. Nevertheless, all of these compounds contain early transition metals, which gives the respective nitride a nucleophilic character. In fact, functionalization of most of the mentioned nitrides has been achieved with electrophiles such as alkyltriflates,<sup>15,146</sup> boranes,<sup>170</sup> silanes<sup>17,171,172</sup> or benzoylchlorides.<sup>71</sup>

The group of *Holland* attempted the oxidation of  $N_2$ -derived  $[Re(N)Cl(PNP)]$  (**XXXVII**,  $PNP = [N(CH_2CH_2P^tBu_2)_2]^-$ ).<sup>173</sup> While outer-sphere oxidants, like ferrocenium, lead to metal centered oxidation to give  $[Re(N)Cl(PNP)]^+$  (**LXIV**), electrophilic O-atom-transfer reagents, like mCPBA (mCPBA = 3-chloroperbenzoic acid) lead to oxidation of the pincer-amide and formation of  $[Re(N)Cl(P^ONP)]$  (**LXV**,  $P^ONP = [ON(CH_2CH_2P^tBu_2)_2]^-$ ), which could not be synthesized upon usage of nucleophilic O-atom-transfer agents. **LXV** was successfully oxidized to give  $[Re(N)Cl(P^ONP)]^+$  (**LXVI**), which could also be obtained upon reaction of **LXIV** with mCPBA. Although, the structural parameters of **LXVI** do not differ significantly from **XXXVII**, the  $M\equiv N$ -moiety reacts with phosphines to give the phosphinimide **LXVII**, which decomposes to **LXIV**,  $OPR_3$  and other products. Hammett-analysis *via* variation of the phosphine substituents imply an electrophilic character of the nitride-ligand, showcasing how the ligand and oxidation-state of the metal influence the reactivity of the nitride-moiety.<sup>173</sup>

Scheme 39: Oxidation of the PNP-pincer-ligand and the Re-center in nucleophilic **XXXVII** change the nitride-phlicity to electrophilic in **LXVI**.<sup>173</sup>

### 1.3 Nitride-Functionalization

The described bonding considerations can also be used to rationalize the instability of the Os(V)-nitride  $[\text{Os}(\text{N})(\text{NH}_3)_5]^{2+}$  (**La**), which was proposed as one of the two initial  $\text{N}_2$ -splitting products upon photolysis of  $[\text{((NH}_3)_5\text{Os}^{\text{II}})(\text{N}_2)(\text{Os}^{\text{III}}(\text{NH}_3)_5)]^{5+}$  (**XLIXa**) (Scheme 40, a). The strong *trans*-influence of the nitride ligand leads to liberation of one  $\text{NH}_3$ -ligand (Scheme 40, b). The  $d^3$ -configuration of the so formed  $[\text{Os}(\text{N})(\text{NH}_3)_4]^{2+}$  (**Ld**) destabilizes the  $\text{Os}\equiv\text{N}$ -bond due to occupation of an anti-bonding orbital. Disproportionation to  $[\text{Os}(\text{N})(\text{NH}_3)_4]^+$  (**Le**) and  $[\text{Os}(\text{N})(\text{NH}_3)_4]^{3+}$  (**Lc**) (Scheme 40, c), starts a cascade reaction, using  $[\text{Os}(\text{N})(\text{NH}_3)_4]^{2+}$  (**Ld**) as reductant, in which one nitride ligand is subsequently reduced and protonated to give  $[(\text{NH}_3)_5\text{Os}(\text{OH}_2)]^{3+}$  (**LXVIII**) (Scheme 40, d).<sup>141</sup>

Scheme 40: Photolytic cleavage of **XLIXa** generates a unstable Os(V)-nitride **Ld**, which subsequently disproportionates and starts a cascade reaction, which finally gives **LXVIII**.<sup>141</sup>

*Cummins'*  $\text{N}_2$ -derived nitride  $[\text{Mo}(\text{N})(\text{N}(\text{R})\text{Ar})_3]$  (**XXXI**) reacts as a nucleophile, as predicted for a  $d^0$ -configured early transition metal nitride. Besides adduct formation with Lewis-acids, such as  $\text{BX}_3$  ( $\text{X} = \text{F}, \text{Cl}$ ),  $\text{AlX}_3$  ( $\text{X} = \text{F}, \text{Cl}, \text{Br}, \text{I}$ ),  $\text{GaCl}_3$ ,  $\text{InCl}_3$ ,  $\text{GeCl}_2$  or  $\text{SnCl}_2$ , the formation of imido-complexes ( $[\text{Mo}=\text{N}-\text{R}]^+$ ) with  $\text{MeI}$ ,  $\text{TMS-OTf}$  or *in situ* prepared  $\text{PhC}(\text{O})\text{-OTf}$  has also been observed.<sup>174</sup>

The methyl-imido complex **LXIX**, obtained upon reaction of **XXXI** with  $\text{MeI}$ , can be deprotonated to yield in the formation of the respective ketimido complex **LXX**, which can be C-methylated to give the ethylimido-complex **LXXI** (Scheme 41, *top*). Remarkably, direct synthesis of the ethylimido-complex upon reaction of **XXXI** with  $\text{EtOTf}$ ,  $\text{EtI}$  or  $[\text{Et}_3\text{O}]\text{BF}_4$ , was not successful.<sup>174</sup> In a related study, the group of *Cummins* was able to transform the  $\text{N}_2$ -derived nitride-ligand into cyanide. Reacting a mixture of  $\text{MeOCH}_2\text{Cl}$  and  ${}^i\text{Pr}_3\text{SiOTf}$  with **XXXI** leads to formation of methoxymethylimide **LXXII**, whose deprotonation gave the respective alkoxyketimide **LXXIII**. Addition of  $\text{SnCl}_2$  as Lewis-acid and  $\text{Me}_2\text{NSiMe}_3$  as Brønsted-base yields in the formation of C-bound  $[\text{Mo}(\text{CN})(\text{N}(\text{R})\text{Ar})_3]$  (**LXXIV**, Scheme 41, *bottom*).<sup>175</sup>

### 1.3 Nitride-Functionalization

Scheme 41: *Top*: Sequential methylation of N<sub>2</sub>-derived **XXXI** forms the ethylimido **LXXI**. *Bottom*: Generation of CN<sup>-</sup> from **XXXI**.<sup>174,175</sup>

While reformation of **XXXI** from **LXXIV** was unsuccessful, the group of Cummins was able to generate organic nitriles R–C≡N from N<sub>2</sub> in a synthetic cycle (Scheme 42).<sup>176</sup> Acylation of N<sub>2</sub>-derived **XXXI** using a RC(O)Cl/Me<sub>3</sub>SiOTf-mixture (R = Me, Ph, <sup>t</sup>Bu) gives the respective acylimide complex **LXXV**, which can be reduced with Mg/anthracene in the presence of Me<sub>3</sub>SiOTf to give the respective trimethylsiloxyketimides **LXXVI**. Liberation of the respective nitrile was achieved *via* addition of a Lewis-acid, such as ZnCl<sub>2</sub> or SnCl<sub>2</sub>, to give Mo(IV)-chloride **LXXVII**. Reduction of **LXXVII** gives [Mo(N(R)Ar)<sub>3</sub>] (**XXX**), which binds and splits N<sub>2</sub> to reform **XXXI**.<sup>176</sup>

Scheme 42: Synthetic cycle to generate organic nitriles from N<sub>2</sub> (R = Me, Ph, <sup>t</sup>Bu).<sup>176</sup>

### 1.3 Nitride-Functionalization

A similar synthetic cycle was achieved with already mentioned heterobimetallic **IV** (Figure 3), which cleaves the  $N_2$ -bond upon reduction to give Mo(VI)-nitride **XXXI** and anionic Nb(V)  $[Nb(N)(N(R)Ar)_3]^-$  (**LXXVIII**,  $R = iPr, Np$ , Scheme 43). The Nb-nitride **LXXVIII** is more reactive and releases the respective organic nitrile directly upon reaction with acyl chlorides under formation of a Nb(V) oxo-complex,  $[Nb(O)(N(R)Ar)_3]$  (**LXXIX**). After reaction of **LXXIX** with trifluoromethanesulfonic anhydride giving  $[Nb(OTf)_2(N(R)Ar)_3]$  (**LXXX**) and reduction with  $CoCp_2$ , the so obtained Nb(IV)-triflate  $[Nb(OTf)(N(R)Ar)_3]$  (**LXXXI**) undergoes salt metathesis with  $Na[Mo(N_2)(N(R)Ar)_3]$  (**LXXXII**) and reforms dinuclear **IV**.<sup>62,177</sup>

Scheme 43: Synthetic cycle for the formation of nitriles from  $N_2$  and acyl chlorides using  $N_2$ -bridged heterobimetallic **IV** ( $R = Ad, Ph, tBu$ ;  $R' = Np, tBu$ ;  $Ar = 3,5-Me_2C_6H_3$ ).<sup>177</sup>

The group of *Schneider* followed a different approach in which re-reduction of the metal-center does not rely on external reductants like in *Cummins'* case. In the first example,  $N_2$ -derived Re(V)-nitride **XXXVII** was used to produce acetonitrile in a synthetic cycle (Scheme 44).<sup>146</sup> In the first step, **XXXVII** is reacted with EtOTf to form the respective Re(V)-ethylimido **LXXXIII**, which can be deprotonated to give the respective ketimide **LXXXIV**. This deprotonation is accompanied by formal two electron reduction from Re(V) to Re(III) in which both electrons formally stem from the CH-bond of the  $\alpha$ -carbon. Further deprotonation of this carbon-atom was reported to result also in two electron reduction of the Re-center and release of acetonitrile. However, the so formed Re(I)-species, **LXXXV**, requires strong acceptor-ligands, like iso-nitriles, for stabilization and does not activate  $N_2$ . Nevertheless, reaction of **LXXXIV** with two equivalents of *N*-chlorosuccinimide (NCS) liberates acetonitrile under formation of the Re(IV)-trichloro-complex **LXXXVI**. Closure of the synthetic cycle was achieved upon reduction of **LXXXVI** with NaHg in the presence of  $N_2$  to reform nitride **XXXVII**.<sup>146</sup> Usage of *in situ* prepared  $PhCH_2OTf$  instead of EtOTf yields in the formation of benzonitrile following an analogue mechanism.<sup>178</sup>

Scheme 44: Synthetic cycle for the generation of acetonitrile from  $N_2$  using a Re-PNP-pincer-platform.<sup>146</sup>

Later the group of *Schneider* utilized  $[Re(N)Cl_2(^H PNP^{iPr})]$  (**XLIIb**) for C-N-coupling in a synthetic cycle (Scheme 45).<sup>71</sup> In contrast to **XXXVII**, functionalization of **XLIIb** does not rely on very strong electrophiles, like alkyltriflates. Therefore C-N-coupling could be achieved using benzoylchloride ( $PhC(O)Cl$ ), which releases a mixture of benzamide ( $PhC(O)NH_2$ ), benzoic acid ( $PhCO_2H$ ) and benzonitrile ( $PhCN$ ). The appearance of benzoic acid and benzonitrile is a result of a reaction of benzoylchloride with immediately formed benzamide. Interestingly, both protons, required for the formation of  $PhC(O)NH_2$ , stem from the ligand backbone, which serves as a  $2H^+/e^-$ -donor and is oxidized to give  $Re(III)$  imine-complex **LXXXVII**. Re-reduction of the ligand backbone was accomplished *via* stepwise addition of  $Li[HBET_3]$  and  $[Ph_2NH_2]Cl$ . The so-formed  $Re(III)$ -trichloro-complex **LXXXVIII** can be reduced under  $N_2$ -atmosphere to yield the  $N_2$ -bridged dinuclear **XIII**. However, the yields following this route are relatively low most likely due to the formation of hydride-complexes. Therefore, the group of *Schneider* investigated the electrochemical reduction of the ligand-backbone using controlled potential electrolysis (CPE). CPE ( $E^{app} = -1.65$  V) of **LXXXVII** in the presence of a suitable acid (2,6-dichlorophenol) yielded **LXXXVIII** almost quantitatively, which allowed its subsequent electrochemical reduction to **XIII** *via* CPE using a lower potential ( $E^{app} = -1.85$  V). Irradiation of **XIII** cleaves to  $N_2$ -bond and reforms **XLIIb** to close the synthetic cycle.<sup>71</sup>

### 1.3 Nitride-Functionalization

Scheme 45: Three step synthetic cycle for the formation of benzamide, benzonitrile and benzoic acid from benzoylchloride and  $\text{N}_2$ , including photolytic  $\text{N}_2$ -cleavage and electrochemical re-reduction of the ligand-backbone.<sup>71</sup>

All above discussed examples illustrate some general aspects and strategies for the incorporation of  $\text{N}_2$  into organic molecules. Cleavage of the strong  $\text{N}\equiv\text{N}$  bond is often accompanied by the formation of strong  $\text{M}\equiv\text{N}$ -bonds, which require strong electrophiles to be functionalized. This drawback can be overcome with different strategies, like for example the formation of strong  $\text{N}\equiv\text{C}$ -bonds, like in nitriles, which counterbalance the high energy demand for  $\text{N}_2$ -cleavage.<sup>146,175-177</sup> Alternatively,  $\text{N}_2$ -splitting into less stabilized nitrides, like in Scheme 45, allows the usage of weaker electrophiles. The reduced thermodynamic driving force typically leads to higher kinetic barriers for  $\text{N}_2$ -cleavage, which may be overcome by photolysis.<sup>71</sup> Re-reduction of the metal-center should ideally proceed without an additional reagent or electrochemically.<sup>179</sup>

### 1.3.3 Generation of cyanate from N<sub>2</sub>-derived nitrides

Sodium and potassium cyanate salts are used in a variety of applications, like steel hardening, in agrochemical processes or also for the synthesis of fine chemicals or pharmaceuticals. The worldwide yearly demand ranges around 8 to 10 Mt, which are industrially produced upon reacting sodium or potassium carbonate with urea at temperatures above 400 °C to give sodium or potassium cyanate, respectively.<sup>180</sup>

Taking into account that urea itself is produced from carbondioxide and ammonia at high pressures (eqn. 1.3), the overall atom-efficiency for the production of cyanates is relatively low.<sup>181</sup>

In an alternative approach, cyanates can be generated directly from a metal-nitride and CO. Reformation of the nitride and eviction of the cyanate ligand requires in principle only the addition of one electron and N<sub>2</sub> (Scheme 46). Besides that no other reagents are required, which marks this reaction as potentially very atom efficient. The reduction can be driven electrochemically or *via* addition of a suitable reductant, in case of potassium the reaction is enthalpically favored by -73.4 kcal·mol<sup>-1</sup>.<sup>179,182,183</sup>

Scheme 46: *left*: An idealized cycle for the formation of cyanate from N<sub>2</sub> and CO. *right*: Overall equations for the formation of potassium cyanate and cyanate.<sup>179,182,183</sup>

Coupling of terminal nitrides with CO has been reported for several, non-N<sub>2</sub>-derived nitrides,<sup>184-189</sup> also the CO-mediated cleavage of N<sub>2</sub> under the formation of cyanate has also been reported (see for example Scheme 13).<sup>18,107,108,110</sup> In contrast, coupling of terminal N<sub>2</sub>-derived nitrides with CO is surprisingly scarce and has, so far, only been reported once.<sup>179,190</sup>

### 1.3 Nitride-Functionalization

*Cummins* presented the coupling of CO with non-N<sub>2</sub>-derived Na[V(N)(N(<sup>t</sup>Bu)Ar)<sub>3</sub>] (**LXXXIX**), which is the vanadium analogue to N<sub>2</sub>-derived **XXXI** (Scheme 47, *top*). Addition of CO to **LXXXIX** results in liberation of NaOCN and formation of [V(N(<sup>t</sup>Bu)Ar)<sub>3</sub>] (**XC**), which is not capable for N<sub>2</sub>-binding and/or -splitting.<sup>186</sup>

In contrast, no reaction with CO was observed for the Nb-analogue, Na[Nb(N)(N(<sup>t</sup>Bu)Ar)<sub>3</sub>] (**XCI**). Instead, reduction of independently prepared [Nb(NCO)(N(<sup>t</sup>Bu)Ar)<sub>3</sub>] (**XCII**) results in the reverse: breakage of the C-N-bond, liberation of CO and formation of nitride **XCI** (Scheme 47, *bottom*).<sup>191</sup>

However, neither for the N<sub>2</sub>-derived Mo(VI)-nitride **XXXI** nor for the N<sub>2</sub>-derived Nb(V)-nitrides [Nb(N)(N(R)Ar)<sub>3</sub>]<sup>-</sup> (**LXXVIII**, R = <sup>i</sup>Pr, Np) CN-coupling with CO was reported. Decarbonylation of the independently prepared cyanate complex, [Mo(NCO)(N(<sup>t</sup>Bu)Ar)<sub>3</sub>] (**XCIII**), was also not feasible.<sup>179</sup>

Scheme 47: *Top*: Coupling of a non-N<sub>2</sub>-derived V(V)-nitride **LXXXIX** with CO results in formation of NaOCN. *Bottom*: Reduction of the Nb(IV)-cyanate **XCII** results in decarbonylation and formation of the Nb(V)-nitride **XCI**.<sup>186,191</sup>

*Cummins* proposed the CN-bond formation in **LXXXIX** to occur *via* nucleophilic attack of the nitride on the incoming carbonyl, although initial coordination of the CO-ligand to the metal-center could not be fully excluded.

Such an alternative mechanism was proposed, supported by DFT-calculations, by the group of *Liddle* for non-N<sub>2</sub>-derived Tren<sup>TIPS</sup>-supported uranium nitrides (Tren<sup>TIPS</sup> = N(CH<sub>2</sub>CH<sub>2</sub>NSi<sup>i</sup>Pr<sub>3</sub>)<sub>3</sub>).<sup>188</sup> Carbonylation of [U(N)(Tren<sup>TIPS</sup>)]<sup>n</sup> (n = 0 **XCIVa**; n = 1- **XCIVb**) results in formation of the respective cyanate complexes [U(NCO)(Tren<sup>TIPS</sup>)]<sup>n</sup> (n = 0 **XCVa**; n = 1- **XCIVb**) (Scheme 48). Notably, the reaction proceeds on very different time-scales depending on the oxidation state. While the carbonylation of the U(VI)-nitride **XCIVa** is slow (≈16 h), the anionic U(V)-congener reacts instantaneously with CO even at -78 °C.<sup>188</sup> Computational examination of the reaction revealed a transition state with a η<sub>CN</sub><sup>2</sup>-bound cyanate-ligand indicating precoordination of the carbonyl-ligand (Scheme 48; *right*). The smaller size of U(VI) compared to U(V) makes such a precoordination more energetically costly, which is expressed in the higher barrier for CN-coupling for the U(VI)-nitride compared to its U(V)-congener.<sup>188</sup>

### 1.3 Nitride-Functionalization

Scheme 48: *left*: Carbonylation of **XCIV** results in CN-coupling to give **XCV** on different time-scales depending on the oxidation state. *right*: The proposed transition state of CN-coupling.<sup>188</sup>

Similar observations were made by the group of *Agapie* using a *para*-terphenyl-diphosphine supported Mo-nitride (**XCVIIa**; Scheme 49). Carbonylation of the formal Mo(IV)-nitride, **XCVIIa**, results in coordination of CO to the metal center and formation of six-coordinate **XCVIIb**, whose further reduction leads to CO loss and reformation of **XCVIIa** accompanied by other decomposition products.<sup>189</sup>

In contrast, two electron-reduction of **XCVIIa** yields formal Mo(II)-nitride **XCVIIc**, which readily reacts with CO to give NaOCN together with the mono- and tris-carbonyl complexes, **XCVIIId** and **XCVIIe**, respectively. Although the mechanism of CN-coupling remains elusive, the different reactivity of **XCVIIc** compared to **XCVIIa** was accounted to its coordinative unsaturation and its lower valency.<sup>189</sup>

Scheme 49: Carbonylation of *Agapie*'s Mo(IV)-nitride **XCVIIa** results in CO coordination, while carbonylation of the corresponding Mo(II)-nitride **XCVIIc** gives NaOCN.<sup>189</sup>

By now, the only example for a full synthetic cycle for the transformation of  $N_2$  and CO into cyanate has been reported by *Kawaguchi* (Scheme 50).<sup>190</sup> Reduction of  $[V(\text{thf})(\text{ONO})]$  (**XCVIIIa**,  $[\text{ONO}]^{3-} = 2,6-(3\text{-}^t\text{Bu}-5\text{-Me}-2\text{-OC}_6\text{H}_2\text{CH}_2)-4\text{-}^t\text{Bu}$  (*p*-tolyl) $\text{NC}_6\text{H}_4$ ) with two equiv. potassium hydride results in formation of the bis-nitride bridged dinuclear  $[\{K(\text{dme})\}_2\{(\mu\text{-N})V(\text{ONO})\}_2]$  (**XCVIIIb**). Oxidation of **XCVIIIb** with benzoquinone results in breakage of the nitride-bridges and formation of the terminal V(V)-nitride  $[V(\text{N})(\text{ONO})]^-$  (**XCVIIIc**).

### 1.3 Nitride-Functionalization

Notably, re-reduction of **XCVIIf** with either KH or  $KC_8$  to give **XCVIIf** was unsuccessful, indicating that **XCVIIf** is no intermediate in the  $N_2$ -splitting process from **XCVIIf** to **XCVIIf**.<sup>190</sup>

Again different selectivity, depending on the oxidation state, was observed. While carbonylation of V(IV)-nitride **XCVIIf** forms a mixture of  $[V(NCO)(ONO)]^-$  (**XCVIIf**) and other unidentified products, reaction of V(V)-nitride **XCVIIf** with CO (22 bar) results in quantitative formation of **XCVIIf** after two days. Liberation of the formed cyanate ligand as KNCO was achieved upon addition of 2-butyne in toluene in quantitative yield. The so formed  $[V(\eta^2-MeCCMe)(ONO)]$  (**XCVIIf**) can be dissolved in THF to give starting compound **XCVIIf**, closing the synthetic cycle.<sup>190</sup>

**XCVIIf** was also functionalized with isocyanides. Addition of excess CN-Xyl (Xyl = 2,6-Me<sub>2</sub>C<sub>6</sub>H<sub>3</sub>) followed by addition of a cryptand forms the corresponding carbodiimide complex **XCVIIf**. Without additional cryptand the potassium ion is bound to the ONO-ligand and the vanadium-ion is pentacoordinated carrying an additional CN-Xyl ligand, which is released upon addition of cryptand. However, addition of alkynes to **XCVIIf** results not in liberation of  $K(NCN-Xyl)$ .<sup>190</sup>

Scheme 50: Synthetic cycle for the transformation of  $N_2$  and CO into cyanate mediated by a V(ONO)-platform.<sup>190</sup>

This example showcases that the formation of cyanate from  $N_2$  and CO, following an  $N_2$ -splitting route (Scheme 46), is feasible. However, catalytic turnover is prevented by the requirement of reductant for  $N_2$ -cleavage and an oxidant to form **XCVIIf**. Another drawback is the need for elevated CO-pressures and the addition of an external reagent, 2-butyne, to release the formed cyanate.<sup>190</sup>

## 1.4 Scope of this work

While there are many examples for N<sub>2</sub>-cleavage using Mo-complexes, tungsten mediated N<sub>2</sub>-splitting is surprisingly rare and has so far only been reported once.

Taking the established [(N<sub>2</sub>){MoCl(PNP)}<sub>2</sub>] (**XI**)<sup>70</sup> as inspiration, the tungsten analogue, [(N<sub>2</sub>){WCl(PNP)}<sub>2</sub>] (**1**), was synthesized and characterized in order to rationalize the influence of the metal center on the structural and spectroscopic properties of such N<sub>2</sub>-bridged dinuclear compounds. To further corroborate the proposed bonding-picture (Scheme 8), the oxidation of **1** and its influence on the degree of N<sub>2</sub>-activation was analyzed.

Previous studies showed, that the selectivity between competing N<sub>2</sub>-reduction and H<sup>+</sup>-reduction relies on many different factors, such as the reduction potential, the acid strength and also the acid counterion (see chapter 1.2.1). Therefore, the reactivity of [(N<sub>2</sub>){WCl(PNP)}<sub>2</sub>] (**1**) with respect to proton-induced N<sub>2</sub>-cleavage shall be examined and compared with the Mo-analogue **XI** to show the impact of the metal-ion changing from Mo to W. Furthermore, the influence of the acid and reaction temperature was deeply examined in order to provide guidelines how to suppress competing proton-reduction.

In comparison to [(N<sub>2</sub>){ReCl(PNP)}<sub>2</sub>] (**XII**), both group 6 congeners, [(N<sub>2</sub>){MCl(PNP)}<sub>2</sub>] (M = Mo **XI**, W **1**), lack two electrons for direct cleavage of the N<sub>2</sub>-bridge.<sup>15,36,70</sup> Therefore, the reduction of **1** is attempted and both chloro-ligands are exchanged *versus* suitable neutral ligands. The targeted { $\pi^{10}\delta^4$ }-compound shall be characterized in terms of its electronic structure to further support the bonding-picture shown in Scheme 8. Due to its  $\pi$ -electron-count, this { $\pi^{10}\delta^4$ }-compound should be capable of N<sub>2</sub>-cleavage, either thermally or photolytically, which will be explored and analyzed.

The obtained nitrides are functionalized *via* CN-coupling reactions aiming the formation of heterocumulenes, whose strong CN-bonds provide some driving force to overcome the cleavage of the strong W $\equiv$ N-bond.<sup>192</sup> In an ideal case, the formed heterocumulene is liberated under reformation of a suitable precursor for N<sub>2</sub>-binding and/or -cleavage, which would allow the formation of the respective heterocumulene in a synthetic cycle providing guidelines towards a catalytic approach.

## 2 Results and Discussion

### 2.1 Synthesis and Characterization of N<sub>2</sub>-bridged Ditungsten-PNP-Complexes

#### 2.1.1 Redox-series [(N<sub>2</sub>){WCl(PNP)}<sub>2</sub>]<sup>n+</sup> (n = 0-2)<sup>a</sup>

Complexation of commercially available WCl<sub>4</sub> with <sup>H</sup>PNP (<sup>H</sup>PNP = HN(CH<sub>2</sub>CH<sub>2</sub>P<sup>t</sup>Bu<sub>2</sub>)<sub>2</sub>) in the presence of NEt<sub>3</sub> as base gives [WCl<sub>3</sub>(PNP)] (**5**) in yields up to 60%. The <sup>1</sup>H NMR spectrum features three sharp, but paramagnetically shifted signals ( $\delta_{\text{H}} = 9.13$  (CH<sub>2</sub>), 0.82 (<sup>t</sup>Bu), -139.5 ppm (CH<sub>2</sub>)), while no signal could be detected in the <sup>31</sup>P{<sup>1</sup>H} NMR spectrum. The magnetic moment in solution ( $\mu_{\text{eff}} = 2.8 \pm 0.1 \mu_{\text{B}}$ ) derived by *Evans'* method is in agreement with the formation of a d<sup>2</sup> high spin complex. The molecular structure obtained by X-ray diffraction (Figure 11) shows a tungsten ion in an octahedral coordination sphere and closely reassembles the molecular structures of the already reported Re- and Mo- analogues [MCl<sub>3</sub>(PNP)] (M = Re (**LXXXVI**), Mo (**XCIX**)).<sup>70,146</sup>

Figure 11: Molecular structure of **5** in the crystal obtained by single crystal X-ray diffraction. Hydrogen atoms were omitted for clarity. Selected bond lengths [Å] and angles [°]: W1-Cl1 2.4020(9), W1-Cl2 2.4137(9), W1-Cl3 2.3811(9), W1-N1 1.938(3), W1-P1 2.5683(9), W1-P2 2.5873(9); Cl1-W1-Cl3 175.71(3), N1-W1-Cl1 91.76(9), N1-W1-Cl2 178.56(9), N1-W1-Cl3 91.91(9), P1-W1-P2 157.28(3).

With successful synthesis of **5** in hand, its N<sub>2</sub>-activation capability was examined. Reduction of **5** with 2 equiv. of NaHg under N<sub>2</sub>-atmosphere in THF yields in the formation of green, N<sub>2</sub>-bridged [(N<sub>2</sub>){WCl(PNP)}<sub>2</sub>] (**1**) in isolated yields up to 66% (Scheme 51). The molecular structure in the solid state features an  $\mu^2:\eta^1:\eta^1$ -N<sub>2</sub> ligand bridging the apical coordination sites of two W ions in distorted square-pyramidal geometry ( $\tau_5 = 0.35$ , Figure 12).<sup>193</sup> Both {WCl(PNP)}-fragments are twisted with respect to another leading to an idealized C<sub>2</sub>-symmetry (Cl1-W1-W1#-Cl1#: 89.59°/92.27°). This twist of the {WCl(PNP)}-units is attributed to the large steric bulk of the <sup>t</sup>Bu-substituents and was also observed for the Re- (**XII**) and Mo-analogues (**XI**).<sup>36,70</sup>

## 2.1 Synthesis and Characterization of N<sub>2</sub>-bridged Ditungsten-PNP-Complexes

Figure 12: Molecular structure of **1** in the crystal obtained by single crystal X-ray diffraction. Hydrogen atoms were omitted for clarity. Furthermore only one of the two independent molecules in the asymmetric unit is shown. Selected bond lengths [Å] and angles [°]: N2-N2# 1.33(4)/1.27(8), W1-Cl1 2.5082(16)/2.576(4), W1-N1 1.938(6)/1.893(11), W1-N2 1.78(2)/1.82(4), W1-P1 2.444(4)/2.468(4), W1-P2 2.483(4)/2.417(8); Cl1-W1-N1 135.67(16)/135.7(4), Cl1-W1-N2 109.4(3)/106.2(7), N1-W1-N2 135.67(16)/135.7(4), N2-N2#-W1 163.8(18)/160(4), P1-W1-P2 156.91(12)/156.8(3).

The C<sub>2</sub>-symmetry persists in solution, as indicated by the presence of two doublets ( $\delta_P = 92.9, 87.8$  ppm) with large *trans*-coupling ( $^2J_{PP} = 147$  Hz) in the  $^{31}\text{P}\{^1\text{H}\}$  NMR spectrum. Upon reduction of **5** under  $^{15}\text{N}_2$ -atmosphere one singlet at 31.1 ppm was observed in the  $^{15}\text{N}\{^1\text{H}\}$  NMR spectrum, confirming the synthesis of  $^{15}\text{N}$ -**1** and atmospheric N<sub>2</sub>-uptake. Comparison of the Raman spectra of  $^{14}\text{N}$ -**1** and  $^{15}\text{N}$ -**1** give rise to the N-N stretching frequency ( $\tilde{\nu}_{\text{NN}}(^{14}\text{N}-\mathbf{1}) = 1392$  cm<sup>-1</sup>,  $\tilde{\nu}_{\text{NN}}(^{15}\text{N}-\mathbf{1}) = 1347$  cm<sup>-1</sup>,  $\lambda_{\text{exc}} = 457$  nm, THF solution), which is in between the values for free hydrazine ( $\tilde{\nu}_{\text{NN}} = 1076$  cm<sup>-1</sup>) and *trans*-diazene ( $\tilde{\nu}_{\text{NN}} = 1529$  cm<sup>-1</sup>) (Table 1).<sup>22</sup> These values imply a relatively high degree of N<sub>2</sub>-activation, which is further supported by the short W-N<sub>2</sub> ( $d_{\text{WN}_2} = 1.78(2)/1.82(4)$  Å) and the long N-N distances ( $d_{\text{NN}} = 1.33(4)/1.27(8)$  Å).

Next the redox chemistry of **1** was examined using cyclic voltammetry (CV, Figure 13). Besides two reversible oxidation waves at low potentials ( $E_1 = -1.39$  V and  $E_2 = -0.91$  V, vs. Fc<sup>+</sup>/Fc in THF) no further redox events could be detected in the range of -2.9 to 0.6 V. Compared to the Mo-analogue (**XI**), which also shows two reversible oxidation events ( $E_1 = -1.14$  V and  $E_2 = -0.64$  V, vs. Fc<sup>+</sup>/Fc in THF), the observed oxidation potentials are cathodically shifted, implying the nature of these oxidations being metal centered.

## 2.1 Synthesis and Characterization of N<sub>2</sub>-bridged Ditungsten-PNP-Complexes

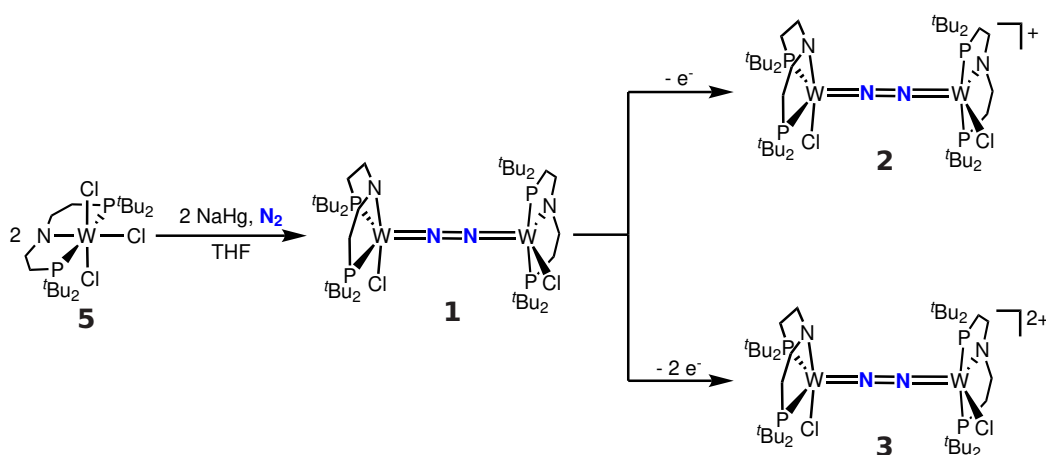

Figure 13: Comparison of the cyclic voltammograms of **1** (blue) and **XI** (red) (both 100 mV/s, THF, Ar).<sup>70</sup>

Chemical oxidation of **1** with either one or two equivalents of silver-salts, results in formation of monocationic  $[(N_2)\{WCl(PNP)\}_2]^+$  (**2**) or dicationic  $[(N_2)\{WCl(PNP)\}_2]^{2+}$  (**3**), respectively (Scheme 51). Stabilization of **3** requires usage of weakly coordinating anions such as  $[BPh_4]^-$  or  $[Al(OC(CF_3)_3)_4]^-$ .

Scheme 51: Synthesis of **1** and its further one or two electron oxidation to **2** and **3**, respectively.

## 2.1 Synthesis and Characterization of N<sub>2</sub>-bridged Ditungsten-PNP-Complexes

Figure 14: *left*: Molecular structure of **2** in the crystal obtained by single crystal X-ray diffraction. Hydrogen atoms, the triflate anion and co-crystallized solvent molecules were omitted for clarity. Selected bond lengths [Å] and angles [°]: N3-N4 1.266(12), W1-Cl1 2.366(3), W2-Cl2 2.446(3), W1-N1 1.993(10), W2-N2 2.093(13), W1-N3 1.781(9), W2-N4 1.813(10), W1-P1 2.524(3), W1-P2 2.522(3), W2-P3 2.504(4), W2-P4 2.471(3); Cl1-W1-N1 136.0(3), Cl2-W2-N2 133.7(3), W1-N3-N4 169.7(8), W2-N3-N4 172.3(10), N1-W1-N3 114.2(4), N2-W2-N4 113.0(5), P1-W1-P2 154.94(10), P3-W2-P4 154.55(12). *right*: EPR-spectrum of **2** (X-band, THF, r.t.).

The molecular structure of monocationic **2** (Figure 14, *left*) shows distinct differences compared to the one of **1**. Although the N-N distance is nearly unchanged ( $d_{\text{NN}} = 1.277(5)$  Å), the bond lengths around each tungsten ion in **2** are slightly different, indicating valence localization due to metal centered oxidation, which is in agreement with the large comproportionation constant ( $K_c \approx 10^8$ ) derived from both oxidation potentials.

The EPR spectrum (X-band, r.t.) of **2** shows an isotopic signal ( $g_{\text{av}} = 1.93$ ) with hyperfine interaction (HFI) with only one tungsten ( $A(^{183}\text{W}) = 220$  MHz) and two phosphorous atoms ( $A(^{31}\text{P}) = 56$  MHz). HFI with the bridging N<sub>2</sub>-ligand was not found, as the <sup>14</sup>N- and <sup>15</sup>N-isotopologues give identical spectra further supporting metal centered oxidation (Figure 14, *right*).

Nevertheless, **2** appears C<sub>2</sub>-symmetric on the slow NMR time scale, as its <sup>1</sup>H NMR spectrum features four intense, but broad and paramagnetically shifted signals ( $\delta_{\text{H}} = 3.13, 2.99, 2.51$  and  $2.38$  ppm), which could be assigned to the <sup>t</sup>Bu-groups, and seven of the expected eight resonances for the ligand backbone.

The N-N stretching frequency ( $\tilde{\nu}_{\text{NN}}(^{14}\text{N-2}) = 1414$  cm<sup>-1</sup>,  $\tilde{\nu}_{\text{NN}}(^{15}\text{N-2}) = 1360$  cm<sup>-1</sup>,  $\lambda_{\text{exc}} = 457$  nm, THF solution) is nearly unimpaired compared to **1**.

## 2.1 Synthesis and Characterization of N<sub>2</sub>-bridged Ditungsten-PNP-Complexes

Figure 15: *left*: Molecular structure of **3** in the crystal obtained by single crystal X-ray diffraction. Hydrogen atoms, the tetraphenylborate-anion and co-crystallized solvent molecules were omitted for clarity. Selected bond lengths [Å] and angles [°]: N2-N2# 1.277(5), W1-Cl1 2.3507(8), W1-N1 1.983(3), W1-N2 1.785(2), W1-P1 2.5535(8), W1-P2 2.5269(8); Cl1-W1-N1 105.53(8), Cl1-W1-N2 142.77(7), N1-W1-N2 111.71(10), N2-N2#-W1 169.7(3), P1-W1-P2 150.21(3). *right*:  $\chi_M T$  vs.  $T$  plot for **2**-[Al(OC(CF<sub>3</sub>)<sub>3</sub>)<sub>4</sub>]<sub>2</sub>. The open circles are the observed susceptibility, the red solid line corresponds to the best fit with the parameters  $g = 1.90$ ,  $J = -59 \text{ cm}^{-1}$ ,  $TIP = 230 \cdot 10^{-6} \text{ cm}^3 \text{ mol}^{-1}$  and  $PI = 0.6\%$  ( $S = 1$ , the blue broken line, PI: paramagnetic impurity).

Two electron oxidation of **1** gives dicationic **3**, whose <sup>1</sup>H NMR spectrum features four intense but paramagnetically shifted signals for the <sup>t</sup>Bu-groups ( $\delta_H = 4.32, 4.19, 3.78$  and  $3.49$  ppm) and eight signals for the ligand backbone, as expected for such a dinuclear C<sub>2</sub>-symmetric molecule. No signal could be detected in the <sup>31</sup>P{<sup>1</sup>H} NMR spectrum. Magnetic characterization of dicationic **3** derived by SQUID magnetometry reveals a  $\chi_M T$  product of  $0.6 \text{ cm}^3 \text{ mol}^{-1} \text{ K}^{-1}$  at r.t., which gradually drops to 0 at about 20 K. The data was fitted to a model with two weakly antiferromagnetically coupled ( $J = -59 \text{ cm}^{-1}$ ) low spin ( $S = 1/2$ ) ions, indicating that the second oxidation is also metal centered (Figure 15, *right*).

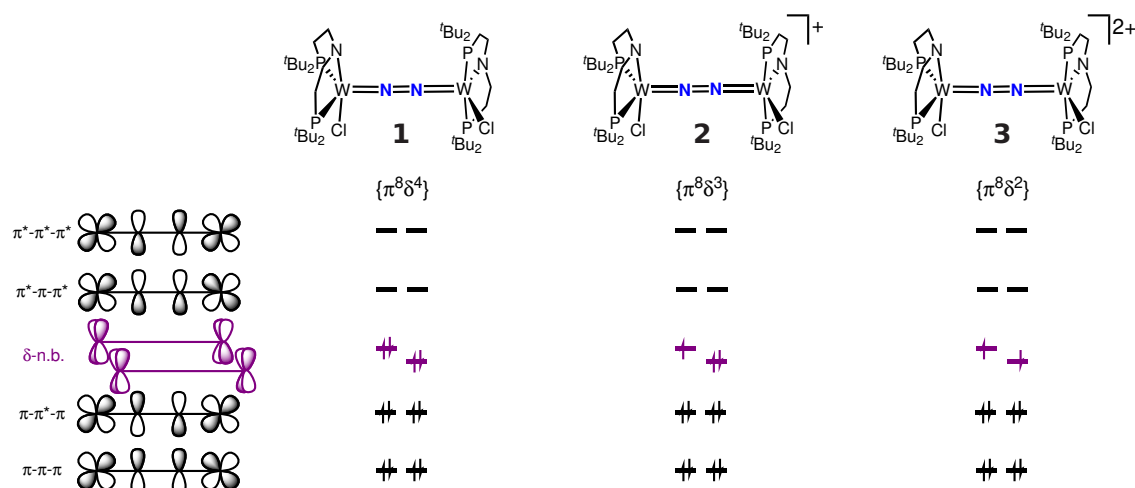

In the solid state dicationic **3** appears C<sub>2</sub>-symmetric with identical bond lengths around each tungsten center (Figure 15, *left*). The NN bond distance ( $d_{NN} = 1.266(12) \text{ Å}$ ) as well as the N-N stretching frequency ( $\tilde{\nu}_{NN}({}^{14}\text{N-3}) = 1400 \text{ cm}^{-1}$ ,  $\tilde{\nu}_{NN}({}^{15}\text{N-3}) = 1356 \text{ cm}^{-1}$ ,  $\lambda_{exc} = 514.5 \text{ nm}$ , THF solution) are both nearly unchanged compared to **1** or **2**.

## 2.1 Synthesis and Characterization of N<sub>2</sub>-bridged Ditungsten-PNP-Complexes

Table 6: Comparison of the structural and spectroscopic features of the bridging N<sub>2</sub> ligand in **1**, **2** and **3** with the Mo-congener **XI** and *Cummins'* dicationic **III**.<sup>61,70</sup>

	<b>1</b>	<b>2</b>	<b>3</b>	<b>XI</b>	<b>III</b>
d <sub>NN</sub> [Å]	1.33(4)/1.27(8)	1.277(5)	1.266(12)	1.258(9)	1.265(5)
$\tilde{\nu}$ ( <sup>14</sup> N <sub>2</sub> ) [cm <sup>-1</sup> ]	1392	1414	1400	1343	1349
$\tilde{\nu}$ ( <sup>15</sup> N <sub>2</sub> ) [cm <sup>-1</sup> ]	1347	1360	1356	-	-

Overall, the structural and spectroscopic features of **1**, **2** and **3** exhibit a unimpaired degree of activation of the bridging N<sub>2</sub>-ligand upon oxidation (Table 6). Following the simple bonding model expressed by the MO-scheme for such N<sub>2</sub>-bridged dinuclear compounds neutral **1** features { $\pi^8\delta^4$ }-configuration (Scheme 52, *left*). The eight  $\pi$ -electrons within the {MNNM}-manifold lead to a relatively high degree of N<sub>2</sub>-activation, similar to the Mo-analogue **XI** or *Cummins'* dicationic **III** (Table 6).<sup>61,70</sup> The small differences are attributed to slightly reduced backbonding of the 5d-metal. The four additional electrons, compared to **III**, are populating metal centered  $\delta$ -orbitals with non-bonding character with respect to the bridging N<sub>2</sub> ligand (Scheme 52).

Scheme 52: Qualitative molecular orbital scheme of **1** (*left*), **2** (*middle*) and **3** (*right*)

One electron oxidation of **1** removes one electron from the  $\delta$ -orbitals to give { $\pi^8\delta^3$ }-configured **2** (Scheme 52, *middle*). Due to the NN-non-bonding character of these orbitals the bridging N<sub>2</sub> ligand remains unaffected, while one of the two tungsten ions gets oxidized, which results in loss of the C<sub>2</sub>-symmetry and a SOMO, which is located on only one metal center. The second oxidation is located on the second tungsten ion and removes another electron from the  $\delta$ -orbitals. Accordingly, both {WCl(PNP)}-fragments become identical and host both one unpaired electron. The orthogonality of the  $\delta$ -orbitals to the {WNNW}-core leads to only weak mutual coupling ( $J(\mathbf{3}) = -59$  cm<sup>-1</sup>) of both tungsten ions *via* the N<sub>2</sub>-bridge.

## 2.1 Synthesis and Characterization of N<sub>2</sub>-bridged Ditungsten-PNP-Complexes

These interpretations are further verified by DFT-calculations.<sup>b</sup> Monocationic **2** was predicted as a doublet with a  $\{\pi^8\delta_1^2\delta_2^1\}$ -configuration (Figure 16, *left*), while dicationic **3** was calculated as an open shell singlet with a  $\{\pi^8\delta_1^1\delta_2^1\}$ -configuration and a low lying triplet state due to weak antiferromagnetic coupling of the two metal-centered spins ( $J_{\text{DFT}}(\mathbf{3}) = -184 \text{ cm}^{-1}$ , Figure 16, *right*).

Figure 16: Spin-density-plots for **2** (*left*) and **3** (*right*).

<sup>b</sup> DFT-calculations were performed by **Dr. Markus Finger** using: M06/def2-TZVPP (SMD: THF) // D3BJ-RJCOSX-PBE0/def2-SVP.

2.1.2 Synthesis and characterization of [(N<sub>2</sub>){W(CO)(PNP)}<sub>2</sub>] (**4**)<sup>c</sup>

Just as its Mo-congener **XI** or *Cummins'* dicationic **III**, [(N<sub>2</sub>){WCl(PNP)}<sub>2</sub>](**1**) is not capable for cleavage of the N<sub>2</sub>-bridge neither thermally (T = 80 °C) nor photolytically (λ > 305 nm), which can be rationalized by the lack of two electrons within the {WNNW}-π-manifold.<sup>22,61,70</sup> As indicated by electrochemical studies (Figure 13), reduction of **1** requires very harsh reductants. Besides protonation, which will be discussed in the next chapter, other attempts were sought to shift the reduction potential to a more suitable range. One strategy for that is the coordination of strong π-acceptor ligands, such as carbonyl or isonitrile, to the vacant coordination site at the metals in order to reduce the electron density at the tungsten-ions. Furthermore, these ligands, especially CO, can be used as spectroscopic probes to quantify the electron density at a metal.<sup>194</sup> In this way the actual amount of electron transfer to the bridging N<sub>2</sub> ligand upon splitting can be estimated, which remains surprisingly ill-defined, due to the high covalency in N<sub>2</sub> bridged dinuclear compounds and in the formed nitride-products.

Addition of two equivalents of CN-<sup>t</sup>Bu to **1** leads to the formation of two products, without full conversion of the starting material, as indicated by <sup>31</sup>P{<sup>1</sup>H} NMR spectroscopy (Figure 17, *top*).

Figure 17: <sup>31</sup>P{<sup>1</sup>H} NMR spectrum of the reaction of **1** with 2 equiv. CN-<sup>t</sup>Bu (*top*) and additional 2 equiv. CN-<sup>t</sup>Bu (*bottom*) in C<sub>6</sub>D<sub>6</sub> at r.t.

## 2.1 Synthesis and Characterization of N<sub>2</sub>-bridged Ditungsten-PNP-Complexes

Upon addition of two further equivalents of CN-<sup>t</sup>Bu all remaining **1** is consumed (Figure 17, *bottom*). Additionally one of the products (Product B) is transformed into the other product (Product A), which was identified as [WCl(CN<sup>t</sup>Bu)<sub>2</sub>(PNP)] (**6**), that could also be synthesized *via* reduction of [WCl<sub>3</sub>(PNP)] (**5**) with two equivalents of NaHg in the presence of CN-<sup>t</sup>Bu (Scheme 53, *left*).

Scheme 53: *left*: Reaction of **1** with CN-<sup>t</sup>Bu leads to partial loss of the bridging N<sub>2</sub>-ligand and formation of **6**. *right*: Molecular structure of **6** in the crystal obtained by single crystal X-ray diffraction. Hydrogen-atoms are omitted for clarity. Furthermore only one of the two independent molecules in the asymmetric unit is shown. Selected bond lengths [Å] and angles [°]: W1-C21 2.034(7), W1-C26 1.996(8), W1-Cl1 2.4830(19), W1-N1 2.018(6), W1-P1 2.465(2), W1-P2 2.507(2); C21-W1-C26 78.7(3), C21-W1-N1 154.4(3), C26-W1-N1 83.0(3), C26-W1-Cl1 149.8(2), P1-W1-P2 154.00(6).

The <sup>31</sup>P{<sup>1</sup>H} NMR spectrum of **6** features one singlet flanked by tungsten satellites at 74.0 ppm. The presence of two signals for the <sup>t</sup>Bu-groups of the CN-<sup>t</sup>Bu and two signals for the <sup>t</sup>Bu-groups of the PNP-ligand in the <sup>1</sup>H NMR spectrum indicate C<sub>s</sub>-symmetry, due to *cis*-coordination of both isonitrile-ligands, which was confirmed by X-ray diffraction (Scheme 53, *right*).

The formation of **6** is consistent with the need of four equivalents CN-<sup>t</sup>Bu and leads to undesired loss of the bridging N<sub>2</sub> ligand. Due to the characteristic <sup>31</sup>P{<sup>1</sup>H} NMR signature, showing two doublets (δ<sub>P</sub> = 63.8, 60.9 ppm) with large *trans*-coupling (<sup>2</sup>J<sub>PP</sub> = 174 Hz), product B was assumed to be dinuclear [(N<sub>2</sub>){W(CN<sup>t</sup>Bu)(PNP)}<sub>2</sub>] (**7**, Scheme 53). Unfortunately, suppression of N<sub>2</sub>-loss *via* usage of another iso-cyanide and/or changing the reaction conditions was unsuccessful. Furthermore, all attempts to isolate and characterize **7** failed due to similar solubility properties compared to **1** and **6**.

## 2.1 Synthesis and Characterization of N<sub>2</sub>-bridged Ditungsten-PNP-Complexes

In contrast to the reaction with isonitriles, short (<20 min) exposure of **1** to CO (1 atm) results in quantitative formation of one product, which was identified as [(N<sub>2</sub>){WCl(CO)(PNP)}<sub>2</sub>] (**8**) (Scheme 54). Longer reaction times lead to the formation of undesired side-products, including [W(CO)<sub>3</sub>(<sup>H</sup>PNP)] (**9**) and [WCl(CO)<sub>2</sub>(PNP)] (**10**) (*vide infra*).

Scheme 54: Reaction of **1** with CO yields **8**, which can be further reduced to give **4**.

The molecular structure of **8** derived by X-ray diffraction (Figure 18, *left*) shows a C<sub>2</sub>-symmetric, dinuclear species with two tungsten ions in an octahedral coordination sphere, the carbonyl-ligand *trans* to the chloro-ligand and the bridging N<sub>2</sub>-ligand *trans* to the pincer-amide-nitrogen.

Compared to **1** the NN-bond length is shorter ( $d_{\text{NN}} = 1.223(4) \text{ \AA}$ ), which, together with the slightly hypsochromically shifted NN stretching frequency ( $\tilde{\nu}_{\text{NN}}(^{14}\text{N-8}) = 1437 \text{ cm}^{-1}$ ,  $\tilde{\nu}_{\text{NN}}(^{15}\text{N-8}) = 1394 \text{ cm}^{-1}$ ,  $\lambda_{\text{exc}} = 457 \text{ nm}$ , THF solution) indicates a slightly weaker degree of activation for the bridging N<sub>2</sub> ligand, which can be attributed to competing backbonding of the CO and N<sub>2</sub> ligands.

In line with the observed C<sub>2</sub>-symmetry in the solid state, the <sup>1</sup>H NMR spectrum features four resonances assigned to the <sup>t</sup>Bu-groups and four resonances for the ligand-backbone. The bridging N<sub>2</sub> ligand of <sup>15</sup>N-**8** was found at -0.7 ppm in the <sup>15</sup>N{<sup>1</sup>H} NMR spectrum. The <sup>31</sup>P{<sup>1</sup>H} NMR spectrum exhibits one singlet ( $\delta_{\text{P}} = 65.9 \text{ ppm}$ ), which shows cross-peaks to all four <sup>t</sup>Bu-signals in the <sup>1</sup>H-<sup>31</sup>P-HMBC NMR spectrum, indicating incidental coincide of both phosphorus sets. The IR spectrum of solid **8** displays two sharp intense bands assigned to the carbonyl-stretching modes at 1883 and 1867 cm<sup>-1</sup>. Both carbonyl-stretches of <sup>15</sup>N-**8** appear at the same energy, indicating no coupling of the CO- and NN-stretches.

Contrary to the CV of **1**, which shows no reductive features up to -2.9 V, the CV of **8** reveals one irreversible reductive feature ( $E_{\text{p}} \approx -2.05 \text{ V}$ , Figure 18, *right*), which was now chemically attempted.

## 2.1 Synthesis and Characterization of N<sub>2</sub>-bridged Ditungsten-PNP-Complexes

Figure 18: *left*: Molecular structure of **8** in the crystal obtained by single crystal X-ray diffraction. Hydrogen-atoms are omitted for clarity. Selected bond lengths [Å] and angles [°]: N3-N4 1.223(4), W1-N1 2.032(3), W1-N3 1.870(3), W2-N2 2.023(3) W2-N4 1.872(3); W1-N3-N4 174.2(3), W2-N4-N3 174.2(3), N1-W1-N3 177.38(13), N2-W2-N4 174.40(13), P1-W1-P2 155.22(3), P3-W2-P4 157.19(3), C41-W1-Cl1 176.5(2), C42-W2-Cl2 176.09(15). *right*: cyclic voltammogram (THF, Ar) at different scan-rates of the reduction of reduction of **8**.

Chemical reduction of **8** with one equivalent of NaHg or Co(Cp<sup>\*</sup>)<sub>2</sub> is incomplete, while usage of two equivalents of reductant results in the formation of deep red [(N<sub>2</sub>){W(CO)(PNP)}<sub>2</sub>] (**4**) (Scheme 54) in isolated yields up to 57%.

In the solid state (Figure 19, *left*), both tungsten ions are in distorted square pyramidal geometry ( $\tau_5 = 0.23$ )<sup>193</sup> with a bridging  $\mu^2$ : $\eta^1$ : $\eta^1$ -N<sub>2</sub> ligand, due to the loss of the chloro-ligands. Similar to **1** both {W(CO)(PNP)}-fragments are twisted with respect to each other, which is again attributed to the steric bulk of the <sup>t</sup>Bu-substituents (C21-W1-W1#-C21#: 87.8°/ 86.6°). Compared to **1** the W-N<sub>2</sub> bond lengths are longer ( $d_{\text{WN}_2} = 1.869(7)$  Å) and the NN bond lengths ( $d_{\text{NN}} = 1.207(14)$  Å) are shorter, hinting to a weaker degree of N<sub>2</sub>-activation, which is supported by the hypsochromically shifted NN-stretching frequency ( $\tilde{\nu}_{\text{NN}}(^{14}\text{N-4}) = 1589$  cm<sup>-1</sup>,  $\tilde{\nu}_{\text{NN}}(^{15}\text{N-4}) = 1540$  cm<sup>-1</sup>,  $\lambda_{\text{exc}} = 633$  nm, THF solution) compared to **1** or **8**. In contrast, the CO-stretching frequencies of solid **4** ( $\tilde{\nu}_{\text{CO}} = 1785, 1741$  cm<sup>-1</sup>, both <sup>14</sup>N-**4** and <sup>15</sup>N-**4** identical) are, compared to **8**, bathochromically shifted, implying stronger back-donation of the metal-ions.

## 2.1 Synthesis and Characterization of N<sub>2</sub>-bridged Ditungsten-PNP-Complexes

Figure 19: *left*: Molecular structure of **4** in the crystal obtained by single crystal X-ray diffraction. Hydrogen-atoms are omitted for clarity. Selected bond lengths [Å] and angles [°]: N2-N2# 1.207(14), W1-C21 1.956(14)/1.97(2), W1-N1 2.043(10)/2.04(2), W1-N2 1.869(7), W1-P1 2.485(3)/2.398(14), W1-P2 2.435(4)/2.517(17); C21-W1-N1 140.9(9)/156(4), P1-W1-P2 154.79(13)/151.7(6), W1-N2-N2# 173.7(7). *right*:  $\chi_M T$  vs.  $T$  plot for **4**. The open circles are the observed susceptibility, the red solid line corresponds to the best fit with the parameters  $g_{av} = 1.74$  and axial zero-field splitting ( $D = 406 \text{ cm}^{-1}$ ) and PI = 8.3% ( $S = 1/2$ , the blue broken line, PI: paramagnetic impurity).

The <sup>1</sup>H NMR of **4** reveals four sharp and paramagnetically shifted signals assigned to the <sup>t</sup>Bu groups and eight signals for the ligand backbone, in line with dinuclear C<sub>2</sub>-symmetry in solution. In contrast, no signal could be found in the <sup>31</sup>P{<sup>1</sup>H} NMR spectrum indicating an open-shell ground state at r.t., which is supported by the magnetic moment in solution ( $\mu_{eff} = 2.3 \pm 0.1 \mu_B$ ) derived by *Evans'* method.

The  $\chi_M T$  vs.  $T$  curve of a powdered sample of **4**, obtained *via* SQUID magnetometry (Figure 19, *right*), exhibits temperature-independent susceptibility below 150 K and could be fitted to a spin Hamiltonian with  $S = 1$ ;  $g_{av} = 1.74$  and large axial zero-field splitting ( $D = 406 \text{ cm}^{-1}$ ).

Similar magnetic behavior has also been observed for a series of 3rd row complexes with octahedral d<sup>4</sup> (Re<sup>III</sup> or Os<sup>IV</sup>)<sup>36,71,195,196</sup> or square pyramidal d<sup>6</sup> (Os<sup>II</sup> or Ir<sup>III</sup>)<sup>197-199</sup> configurations. The temperature independent paramagnetism was rationalized by an electronic triplet state that is strongly split by spin-orbit coupling, which results in an energetically well separated ( $\gg k_B T$ ) ground state ( $J = 0$ ) that experiences only second order paramagnetism through mixing with excited states.<sup>195,200</sup> In contrast to **4** the <sup>1</sup>H NMR spectra of most of these compounds reveal sharp signals with resolved  $J$ -coupling as well as sharp, but paramagnetically shifted resonances in the <sup>31</sup>P{<sup>1</sup>H} or <sup>15</sup>N{<sup>1</sup>H} NMR spectra, respectively (for example [(N<sub>2</sub>){ReCl<sub>2</sub>(<sup>H</sup>PNP<sup>i</sup>Pr)}<sub>2</sub>](**XIII**):  $\delta_P = -370.6$  (d, <sup>2</sup>J<sub>PP} = 236.9 Hz) and  $-380.4$  (d, <sup>2</sup>J<sub>PP} = 237.2 Hz);  $\delta_N = -1113$  ppm).<sup>71</sup></sub></sub>

## 2.1 Synthesis and Characterization of N<sub>2</sub>-bridged Ditungsten-PNP-Complexes

These differences are in line with the non-linear behavior of the  $\chi_M T$  vs.  $T$  curve above 150 K, which implies thermal population of the excited state. The weaker stabilization of the  $J = 0$  ground state in **4**, compared to Re or Os, suggests a smaller effective spin-orbit coupling parameter  $\zeta_{\text{eff}}$  most likely due to a high degree of covalency.<sup>196,201</sup>

Overall, these observations support the simple bonding model expressed by the MO-scheme for such N<sub>2</sub>-bridged dinuclear compounds described earlier (Figure 20, left). Compared to **1**, **4** features two additional electrons within the {WNNW}-core, which are occupying the  $\pi^*-\pi-\pi^*$ -orbitals, whose NN-bonding character leads to a weaker degree of N<sub>2</sub>-activation. The degree of activation compares well with other  $\pi^{10}$ -configured N<sub>2</sub>-bridged dinuclear compounds, such as *Schneider's* ReCl-congener (**XII**) and *Cummins'* neutral **I** (Figure 20, right).<sup>36,60</sup> However, the bathochromic shift of the carbonyl-stretching frequencies, compared to **8**, as well as the magnetic properties of **4**, indicate a high degree of covalency within the {WNNW}- $\pi$ -core.

These observations are further supported by computational analysis,<sup>d</sup> which found a thermodynamic preference of a triplet-ground state over a closed-shell singlet-ground-state by 1.2 kcal·mol<sup>-1</sup>, while no clear open-shell-singlet structure could be identified.

Figure 20: left: qualitative MO-scheme for end-on N<sub>2</sub>-bridged compound with idealized fourfold symmetry. right: Comparison of the structural and spectroscopic features of **4**, *Schneider's* ReCl-congener **XII** and *Cummins'* neutral **I**.<sup>36,60</sup> (\* computed value)

In summary, the initial approach of enabling reduction of **1** via addition of  $\pi$ -acceptor ligand was successful. The electronic structure of so-obtained **4** was deeply examined and supports the qualitative MO-scheme for such end-on N<sub>2</sub>-bridged dinuclear compounds with idealized fourfold symmetry. The presence of ten electrons within the  $\pi$ -manifold is predestined for breakage of the NN-bond, which will be examined and discussed in chapter 2.3.

<sup>d</sup> DFT-calculations were performed by Prof. Dr. Vera Krewald and M.Sc. Severine Rupp using: PBE/def2-TZVP,def2-SVP.

## 2.2 Proton induced N<sub>2</sub>-cleavage versus proton reduction<sup>e</sup>

As already discussed, [(N<sub>2</sub>){WCl(PNP)}<sub>2</sub>] (**1**) is, just as its Mo-analogue **XI**, not capable for N<sub>2</sub>-cleavage neither thermally (T = 80 °C) nor photolytically (λ > 305 nm). However, cleavage of the NN bond in **XI** can be induced upon pincer protonation (Scheme 26), which was now attempted with **1** to investigate if and how the cathodically shifted oxidation potentials of **1** compared to **XI** (Figure 13) influence the reactivity.<sup>70</sup>

Protonation of **1** with two equiv. of triflic acid at -78 °C and gradual warming to r.t. leads to formation of the corresponding W(V)-nitride, [W(N)Cl(<sup>H</sup>PNP)]<sup>+</sup> (**11**). In the solid state, **11** features a square pyramidally coordinated tungsten ion with the nitride ligand on the apical site (Figure 21, left). The triflate anion is hydrogen bonding to the amine proton of the ligand backbone, as indicated by the short NH...O-distance (2.03(3) Å). The W≡N-bond length (d<sub>WN</sub> = 1.679(2) Å) as well as the W≡N stretching frequency detected in the IR of solid **11** (ν̃<sub>WN</sub>(<sup>14</sup>N-**11**) = 1058 cm<sup>-1</sup>, ν̃<sub>WN</sub>(<sup>15</sup>N-**11**) = 1029 cm<sup>-1</sup>) are in the typical range found for other tungsten-nitrides.<sup>202–205</sup> Due to paramagnetism **11** is NMR silent, but features an isotropic signal (g<sub>av</sub> = 1.93) in the X-band EPR spectrum (THF, r.t.) with hyperfine interactions (HFI) to the two phosphorous (A(<sup>31</sup>P) = 56 MHz) and the tungsten nuclei (A(<sup>183</sup>W) = 220 MHz) (Figure 21, right).

Figure 21: *left*: Molecular structure of **11** in the crystal obtained by single crystal X-ray diffraction. Hydrogen-atoms, with exception of H111, and co-crystallized solvent molecules are omitted for clarity. Selected bond lengths [Å] and angles [°]: W1-Cl1 2.3657(7), W1-N1 2.202(2) W1-N2 1.679(2), W1-P1 2.5308(7), W1-P2 2.5352(7); N1-W1-Cl1 154.83(6), N1-W1-N2 99.26(10), P1-W1-P2 152.54(2). *right*: EPR-Spectrum (X-band, THF, r.t.) of **11**.

<sup>e</sup> Parts of this work have been published in: "Selectivity of tungsten mediated dinitrogen splitting vs. proton reduction", B. Schluschaß, J. Abbenseth, S. Demeshko, M. Finger, A. Franke, C. Herwig, C. Würtele, I. Ivanovic-Burmazovic, C. Limberg, J. Telsler, S. Schneider, *Chemical Science*, **2019**, *10*, 10275-10282.

## 2.2 Proton induced N<sub>2</sub>-cleavage *versus* proton reduction

In contrast to the Mo-analogue (**XI**), the selectivity of protonation induced N<sub>2</sub>-cleavage in case of **1** strongly relies on the reaction conditions. For instance, the addition of two equivalents of triflic acid to **1** at r.t. leads to low splitting yields and substantial amounts of the oxidation products **2** and **3**.

The selectivity was further tuned upon usage of two equivalents of a strong acid with a non-coordinating anion, like [H(OEt<sub>2</sub>)<sub>2</sub>][Al(OC(CF<sub>3</sub>)<sub>3</sub>)<sub>4</sub>] or [H(OEt<sub>2</sub>)<sub>2</sub>][BAR<sub>24</sub><sup>F</sup>]. In both cases, the addition to **1** lead, independent of the reaction temperature, exclusively to the formation of dicationic **3** and H<sub>2</sub>, which was detected in the head-space of the reaction *via* gas chromatography (Scheme 55).

Scheme 55: Protonation of **1** leads either to N<sub>2</sub>-cleavage and formation of **11** or to proton-reduction and formation of **3**.

The influence of the acid counteranion was further probed by usage of triethylammonium salts. Protonation of **1** with two equiv. of [HNEt<sub>3</sub>][BAR<sub>24</sub><sup>F</sup>] proceeds slowly and leads to selective formation of monocationic **2** as indicated by *in situ* HR-ESI-MS, EPR and NMR. The slower reaction as well as the not observed second oxidation is explained by the higher pK<sub>a</sub> of [HNEt<sub>3</sub><sup>+</sup>] compared to [H(OEt<sub>2</sub>)<sub>2</sub>][BAR<sub>24</sub><sup>F</sup>] or triflic acid.<sup>206</sup> However, the yield in **2** decreases down to only 30%, if two equiv. of [HNEt<sub>3</sub>]OTf are used. As indicated by *in situ* HR-ESI-MS, the only other product formed is splitting product **11**, which showcases that the selectivity of the reaction heavily relies on the acid counteranion (Scheme 56), as it has also been reported by *Nishibayashi* for catalytic nitrogen fixation (see chapter 1.2.1, Table 4).<sup>9</sup> Hence, **1** was also reacted with two equiv. of [HNEt<sub>3</sub>]Cl, which lead to sluggish mixtures with substantial amounts of trichloride **5** and was therefore not further examined.

## 2.2 Proton induced N<sub>2</sub>-cleavage *versus* proton reduction

Scheme 56: Anion dependence upon protonation of **1** with different [HNEt<sub>3</sub><sup>+</sup>]<sup>+</sup>X salts.

In order to rationalize the origin of this anion dependent selectivity, **1** was also protonated with one equiv. of different Brønsted acids. At r.t. all used acids (HOTf, [H(OEt<sub>2</sub>)<sub>2</sub>][BAR<sup>F</sup><sub>24</sub>], [H(OEt<sub>2</sub>)<sub>2</sub>][Al(OC(CF<sub>3</sub>)<sub>3</sub>)<sub>4</sub>], [LutH]<sup>+</sup> or [HNEt<sub>3</sub>]<sup>+</sup>) lead to exclusive formation of monocationic **2** and H<sub>2</sub>, which was again detected *via* gas chromatography in the head-space of the reaction.

Significant differences between [H(OEt<sub>2</sub>)<sub>2</sub>][BAR<sup>F</sup><sub>24</sub>]<sup>-</sup> and HOTf were observed, when the reaction was carried out at low temperatures. Protonation of **1** with one equiv. triflic acid leads to immediate disappearance of all NMR-signals belonging to **1** and appearance of a new diamagnetic intermediate. The presence of four doublets in the <sup>31</sup>P{<sup>1</sup>H} NMR spectrum (Figure 22, *left*) with identical integrals indicate the loss of the C<sub>2</sub>-axis and formation of a C<sub>1</sub>-symmetric dinuclear complex. If the same reaction is carried out with the <sup>15</sup>N-isotopologue, <sup>15</sup>N-**1**, the <sup>15</sup>N{<sup>1</sup>H} NMR spectrum (Figure 22, *right*) shows two doublets (δ<sub>N</sub> = 27 and 24 ppm; <sup>1</sup>J<sub>NN</sub> = 10 Hz) close to the resonance found for <sup>15</sup>N-**1**, which corroborates the formation of a C<sub>1</sub>-symmetric complex and excludes protonation of the bridging N<sub>2</sub> ligand. Ligand protonation within [(<sup>H</sup>PNP)ClW-(N<sub>2</sub>)-WCl(PNP)]<sup>+</sup> (**12**) could be confirmed by a <sup>1</sup>H NMR signal at 5.41 ppm with typical N-H broadened triplet fine-structure, which shows a cross-peak with the pincer-nitrogen in the <sup>1</sup>H-<sup>15</sup>N HSQC NMR spectrum and coupling to the ligand backbone signals in the <sup>1</sup>H COSY NMR spectrum.

## 2.2 Proton induced N<sub>2</sub>-cleavage *versus* proton reduction

Figure 22:  $^{31}\text{P}\{^1\text{H}\}$  (left) and  $^{15}\text{N}\{^1\text{H}\}$  NMR spectra (right) of **12** in  $\text{THF-d}_8$  at  $-35\text{ }^\circ\text{C}$ .

In contrast to triflic acid, usage of one equiv.  $[\text{H}(\text{OEt}_2)_2][\text{BAR}_{24}^{\text{F}}]$  instantaneously gives monocationic **2** even at temperatures down to  $-75\text{ }^\circ\text{C}$  (Scheme 57), which implies stabilization of **12** by the triflate anion. Contact-ion pair formation of the triflate anion with **12** could be confirmed *via*  $^{19}\text{F}$  and  $^1\text{H}$  DOSY NMR at  $-35\text{ }^\circ\text{C}$ . The diffusion coefficient of the triflate anion in **12**-OTf ( $D = 2.29 \cdot 10^{-6}\text{ cm}^2\text{s}^{-1}$ ) is significantly shifted compared to free triflic acid ( $D = 5.11 \cdot 10^{-6}\text{ cm}^2\text{s}^{-1}$ ) and very close to the diffusion coefficient found for the cation ( $D = 2.18\text{-}2.14 \cdot 10^{-6}\text{ cm}^2\text{s}^{-1}$ ). This interaction is attributed to hydrogen-bonding of the triflate anion with the pincer N-H proton as found in the solid state of **11**-OTf.

Scheme 57: Protonation of **1** with one equiv.  $[\text{H}(\text{OEt}_2)_2][\text{BAR}_{24}^{\text{F}}]$  or HOTf at low temperatures.

## 2.2 Proton induced N<sub>2</sub>-cleavage *versus* proton reduction

Addition of two equiv. triflic acid to **1** at -60 °C leads to a color change from green to yellow, disappearance of all signals in the <sup>31</sup>P{<sup>1</sup>H} NMR spectrum and new broad, paramagnetically shifted resonances in the <sup>1</sup>H NMR spectrum. In analogy to the Mo-congener **XI**, it was assumed, that the second protonation occurs on the second pincer unit to give [(N<sub>2</sub>){WCl(<sup>t</sup>PNP)}<sub>2</sub>]<sup>2+</sup> (**13**). The magnetic moment in solution was determined *via Evans'* method to  $\mu_{\text{eff}} = 4.7 \pm 0.1 \mu_{\text{B}}$ , close to the spin-only value for a quintet ground state ( $\mu_{\text{eff}} = 4.9 \mu_{\text{B}}$ ). Upon raising the temperature to r.t. the yellow color fades and all signals in the <sup>1</sup>H NMR spectrum disappear in line with formation of pale NMR-silent **11**.

Scheme 58: Proposed mechanism of tungsten mediated proton induced N<sub>2</sub>-splitting.

Overall it is proposed, that N<sub>2</sub>-cleavage of **1** to give **11** arises from protonation of both pincer units, which changes the electronic configuration from a { $\pi^8\delta^4$ }-configuration within the {WNNW}-manifold to a { $\pi^{10}\delta^2$ } configuration as is was already described for the Mo-analogue **XI** (Scheme 58).<sup>70</sup> However, this mechanism does not explain, how proton reduction to give H<sub>2</sub> and **2** or **3** occurs. Therefore, the kinetics of proton reduction were studied *via UVvis* spectroscopy using [HNEt<sub>3</sub>][BAR<sub>24</sub><sup>F</sup>] as acid, which gives monocationic **2** selectively within a convenient timescale even under pseudo first-order conditions.

Addition of [HNEt<sub>3</sub>][BAR<sub>24</sub><sup>F</sup>] to a THF solution of **1** leads to an immediate drop of the absorbance without any change in the absorption maxima, implying only small changes in the electronic structure (Figure 23, *left*). From the acid concentration dependency of this drop, the equilibrium constant ( $K_1 = 1592 \pm 578 \text{ L}\cdot\text{mol}^{-1}$ ) and the forward rate ( $k_1 = 163 \pm 47 \text{ L}\cdot\text{mol}^{-1}\cdot\text{s}^{-1}$ ) of the first protonation step could be derived (Figure 23, *right*).

## 2.2 Proton induced N<sub>2</sub>-cleavage *versus* proton reduction

Figure 23: *left*: Exemplary UVvis spectrum of the protonation of **1** with [HNEt<sub>3</sub>][BAR<sub>24</sub><sup>F</sup>]. The blue trace represents the UVvis spectrum of pure **1**, the orange one directly after the addition of acid and the red one after 5 h of reaction time. *right*: plot of the absorbance at 400 nm directly after the addition of acid vs acid-concentration with fitting curve to determine K<sub>1</sub> (R<sup>2</sup>=0.998).

Under pseudo first order conditions ( $c_0([\text{HNEt}_3]^+)/c_0(\mathbf{1}) = 10\text{-}25$ ) this first fast step is followed by another significantly slower, mono-exponential decay, which was monitored over 5 h (Figure 24, *left*). Thereby, the derived rate constant,  $k_{\text{obs}(2)}$ , shows a linear dependency in acid concentration (Figure 24, *right*), which points to a slow, irreversible second protonation step after the initial, fast pre-equilibrium K<sub>1</sub>.

Figure 24: *left*: absorbance (at 607 nm) vs. time plot for different acid concentrations. The red lines represent the fitting curves, while the dots show the measured absorbance. *right*: plot of the determined  $k_{\text{obs}(2)}$  vs acid concentration, showing linear dependence as indicated by the red line.

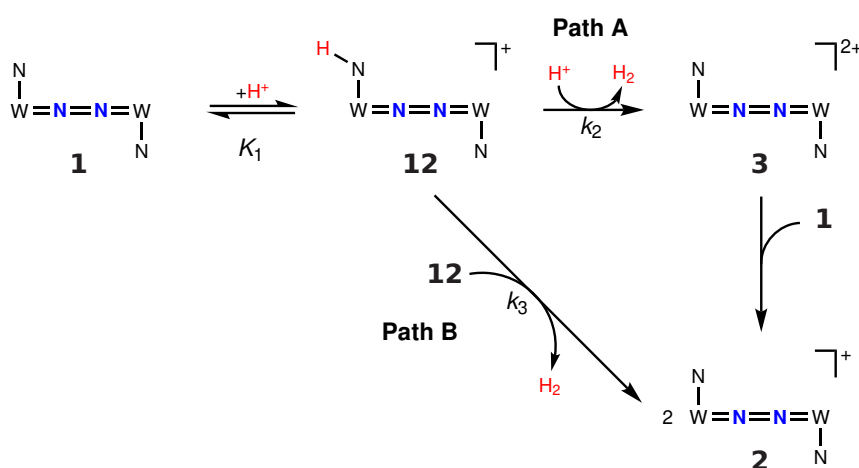

## 2.2 Proton induced N<sub>2</sub>-cleavage *versus* proton reduction

Nevertheless, the non-zero intercept implies the presence of at least one competitive pathway at low concentrations of acid. Therefore, the rate constant  $k_{\text{obs}(2)}$  was expressed by eqn. 2.4 as a result of the minimum kinetic model outlined in Scheme 59:

$$k_{\text{obs}(2)} = \frac{k_2 K_1 [\text{H}^+]^2}{1 + K_1 [\text{H}^+]} + k_{3,\text{obs}} \quad (2.4)$$

The first term represents a pathway in which **1** is initially protonated to give **12**. Second protonation of **12** results in irreversible H<sub>2</sub> loss and formation of dicationic **3**, which rapidly comproportionates with neutral **1** to give two equiv. of monocationic **2**, in line with the large comproportionation constant ( $K_c \approx 10^8$ ) derived from electrochemical studies (Scheme 59, Path A). The second term in eqn. 2.4 accounts for a bimolecular decay of **12** as an alternative pathway at low concentrations of acid (Scheme 59, Path B).

Under pseudo first-order conditions in acid (10-25 equiv.) the experimental data could be fitted to eqn. 2.4 upon preservation of  $K_1$  to give the rate constant  $k_2 = 0.0018 \pm 0.001 \text{ L}\cdot\text{mol}^{-1}\cdot\text{s}^{-1}$ . The rate constant  $k_3$ , assigned to a bimolecular reaction of **12** at low acid concentrations, was derived from the initial rate of the reaction of **1** with one equiv. of  $[\text{HNEt}_3]^+$  ( $k_3 = 0.4 \text{ L}\cdot\text{mol}^{-1}\cdot\text{s}^{-1}$ ). The alternative pathway, that follows the reduction of **12** by **1** was excluded due to the considerably smaller derived rate constant ( $k'_3 = 0.12 \text{ L}\cdot\text{mol}^{-1}\cdot\text{s}^{-1}$ ).

Scheme 59: Proposed mechanistic pathways for proton reduction at high (Path A) and low (Path B) concentrations of acid.

From the kinetic analysis two pathways can be proposed, both proceeding through the spectroscopically characterized intermediate **12**. At low acid concentrations, proton reduction occurs from a bimolecular reaction of **12** (Scheme 59, Path B), which explains its decay even in the absence of acid and the selective formation of monocationic **2** and H<sub>2</sub> upon usage of one equiv. of acid. Similar observations have been

## 2.2 Proton induced N<sub>2</sub>-cleavage versus proton reduction

made by *Peters* for his [(Fe(TBP))<sup>+</sup>]-system (**XXVI**, Figure 8).<sup>126</sup> In case of excess acid, the second pathway (Scheme 59, Path A) becomes predominant. This pathway explains the formation of dicationic **3** upon protonation of **1** with two equiv. of [H(OEt<sub>2</sub>)<sub>2</sub>][Al(OC(CF<sub>3</sub>)<sub>3</sub>)<sub>4</sub>] or [H(OEt<sub>2</sub>)<sub>2</sub>][BAr<sub>24</sub><sup>F</sup>].

Besides these two pathways, the N<sub>2</sub>-splitting product **11** is also (at r.t.) or exclusively (at low T) obtained in the presence of triflate as anion. To rationalize the influence of the counteranion the protonation of **1** was studied computationally, using truncated [HNMe<sub>3</sub>]<sup>+</sup> as model acid (Scheme 60).<sup>f</sup>

Scheme 60: Computed energy profile for proton induced N<sub>2</sub>-cleavage (*left branch*) and proton reduction (*right branch*) both *via* double protonation of **1** at 25 °C in the absence (solid line) and in the presence (dashed line) of triflate as counteranion. The italic energies represent the calculated barriers for N<sub>2</sub>-splitting from **13** and **13**<sup>OTf<sub>2</sub></sup> to give **11** and **11**<sup>OTf</sup>, respectively.

For the first step two different protonation sites, a tungsten ion and a pincer nitrogen, have been considered. Protonation of one tungsten ion and formation of a hydride product [(PNP)W(H)Cl-(N<sub>2</sub>)-WCl(PNP)]<sup>+</sup> (**14**) with a diamagnetic ground state was calculated to be the global minimum ( $\Delta G_{298\text{ K}}^{\circ} = -4.7 \text{ kcal}\cdot\text{mol}^{-1}$ ) in excellent agreement with the experimentally derived equilibrium constant  $K_1$ . Similar to the protonation of a PCP-Mo(IV)-nitride with [HNEt<sub>3</sub>][BAr<sub>24</sub><sup>F</sup>] reported by *Schrock*,<sup>14</sup> the structure of **14** features a hydride bridging one pincer phosphorous atom and the tungsten center. Unfortunately, all attempts to experimentally verify the formation of a hydride were unsuccessful. Protonation of the pincer nitrogen to give **12** was calculated to be slightly less exergonic ( $\Delta G_{298\text{ K}}^{\circ} = -2.9 \text{ kcal}\cdot\text{mol}^{-1}$ ).

<sup>f</sup> DFT-calculations were performed by **Dr. Markus Finger** using: M06/def2-TZVPP (SMD: THF) // D3BJ-RJCOSX-PBE0/def2-SVP.

## 2.2 Proton induced N<sub>2</sub>-cleavage *versus* proton reduction

---

However, the situation changes in the presence of a triflate anion. Upon usage of [HNMe<sub>3</sub>]OTf protonation of the pincer backbone becomes more favorable due to stabilization of the pincer amine moiety *via* hydrogen bonding of the triflate anion ( $\Delta G_{298\text{ K}}^{\circ} = -5.0 \text{ kcal}\cdot\text{mol}^{-1}$ ). Since hydride **14** is not involved in hydrogen bonding, pincer protonated **12**<sup>OTf</sup> is the global minimum in presence of a triflate counteranion. Nevertheless, both protonation products should be in rapid equilibrium, which is slightly shifted towards hydride **14** in the absence and slightly shifted towards pincer protonated **12**-OTf in the presence of a triflate counteranion. In all cases hydrogen bonding towards NMe<sub>3</sub> was not observed, most likely due to steric reasons.

The second protonation leads either to H<sub>2</sub>-evolution or N<sub>2</sub>-cleavage. The formation of H<sub>2</sub> and dicationic **3** was calculated to be exergonic ( $\Delta G_{298\text{ K}}^{\circ} = -12.8 \text{ kcal}\cdot\text{mol}^{-1}$ , with respect to **1**; Scheme 60, *right branch*). As most reasonable pathway, the protonation of hydride **14** was considered. As a result a dihydrogen intermediate [(PNP)W(H<sub>2</sub>)Cl(N<sub>2</sub>)-WCl(PNP)]<sup>2+</sup> (**15**) is formed, which is unstable and releases H<sub>2</sub> without barrier. Therefore, the free energy of **15** ( $\Delta G_{298\text{ K}}^{\circ} = 15.2 \text{ kcal}\cdot\text{mol}^{-1}$ ) was used to estimate the kinetic barrier for the protonation of hydride **14**. The so obtained value ( $\Delta\Delta G_{298\text{ K}}^{\circ} = 19.7 \text{ kcal}\cdot\text{mol}^{-1}$  with respect to **14**) is in very good agreement with the experimentally derived barrier for Path A ( $\Delta G_{\text{eff}}^{\ddagger} = 19 \text{ kcal}\cdot\text{mol}^{-1}$ ).

Cleavage of the bridging N<sub>2</sub>-unit and formation of nitride **11**, was calculated to proceed *via* protonation of the second pincer unit, similar to the Mo-analogue **XI** (Scheme 60, *left branch*).<sup>70</sup> The doubly pincer protonated [(N<sub>2</sub>){WCl(HPNP)}<sub>2</sub>]<sup>2+</sup> (**13**) was calculated to adopt a quintet ground-state (*S* = 2), in agreement with the experimentally derived magnetic moment for **13**<sup>OTf2</sup> ( $\mu_{\text{eff}} = 4.7 \pm 0.1 \mu_{\text{B}}$ ). In the absence of a triflate anion diprotonated **13** was located at  $\Delta G_{298\text{ K}}^{\circ} = 5.0 \text{ kcal}\cdot\text{mol}^{-1}$  (with respect to **1**). N<sub>2</sub>-cleavage into nitride **11** is strongly exergonic ( $\Delta G_{298\text{ K}}^{\circ} = -49.7 \text{ kcal}\cdot\text{mol}^{-1}$ ) with a kinetic barrier of  $\Delta G_{298\text{ K}}^{\ddagger} = 21.7 \text{ kcal}\cdot\text{mol}^{-1}$ , in a comparable range to the experimentally derived values for the Re- (**XII**) and Mo-analogues (**XI**).<sup>36,70</sup>

Starting from the most stable monoprotection product in the absence of triflate, hydride **14**, the effective barrier for N<sub>2</sub>-cleavage ( $\Delta G_{\text{eff}}^{\ddagger} = 31.4 \text{ kcal}\cdot\text{mol}^{-1}$ ) is considerably higher than the estimated barrier for H<sub>2</sub>-evolution ( $\Delta G_{\text{eff}}^{\ddagger} = 19.9 \text{ kcal}\cdot\text{mol}^{-1}$ ), which explains the observed selective formation of H<sub>2</sub> upon usage of [HNEt<sub>3</sub>][BAR<sub>24</sub><sup>F</sup>].

In the presence of triflate the relative energetics of these two pathways change. As already described, the global minimum of the first protonation in the presence of triflate is **12**<sup>OTf</sup>. Accordingly, the effective barrier for H<sub>2</sub>-evolution is slightly increased by +0.3 kcal·mol<sup>-1</sup>. Similar to the stabilization of monoprotection product **12**<sup>OTf</sup>, doubly pincer protonated **13**<sup>OTf2</sup> gets stabilized by hydrogen bonding of the pincer amine moieties with the triflate counteranions by -8.8 kcal·mol<sup>-1</sup>, which decreases the effective barrier for N<sub>2</sub>-cleavage. As a consequence both reaction pathways feature almost isoenergetic effective barriers (Proton reduction:  $\Delta G_{\text{eff}}^{\ddagger} = 20.2 \text{ kcal}\cdot\text{mol}^{-1}$ ; N<sub>2</sub>-cleavage:  $\Delta G_{\text{eff}}^{\ddagger} = 21.5 \text{ kcal}\cdot\text{mol}^{-1}$ ; both vs. **12**<sup>OTf</sup>), in full agreement with the experimental findings upon protonation with [HNEt<sub>3</sub>]OTf.

## 2.2 Proton induced N<sub>2</sub>-cleavage *versus* proton reduction

Overall, the selectivity upon protonation with [HNMe<sub>3</sub>]<sup>+</sup>-salts follows the *Curtin-Hammett-principle*.<sup>207</sup> The pre-equilibrium is modulated by N-H hydrogen bonding to the counteranion, while the selectivity is only depending on the effective barrier for H<sub>2</sub>-evolution and N<sub>2</sub>-cleavage, which is strongly influenced by hydrogen bonding of the two N-H moieties with the triflate counteranions.

This picture changes if triflic acid is used instead of [HNMe<sub>3</sub>]<sup>+</sup>, due to the lower pK<sub>a</sub> (pK<sub>a</sub><sup>THF</sup>([HNMe<sub>3</sub>]<sup>+</sup>)-pK<sub>a</sub><sup>THF</sup>(HOTf) = 4.7) (Scheme 61, black).<sup>206</sup> The pre-equilibrium between hydride **14** (ΔG<sub>298 K</sub><sup>o</sup> = -13.5 kcal·mol<sup>-1</sup>) and ligand protonated **12**<sup>OTf</sup> (ΔG<sub>298 K</sub><sup>o</sup> = -13.9 kcal·mol<sup>-1</sup>) is slightly shifted towards the latter, due to its stabilization *via* hydrogen bonding. Furthermore, the effective barriers for N<sub>2</sub>-cleavage and H<sub>2</sub>-evolution become close in energy (Proton reduction: ΔG<sub>eff</sub><sup>‡</sup> = 11.5 kcal·mol<sup>-1</sup>; N<sub>2</sub>-cleavage: ΔG<sub>eff</sub><sup>‡</sup> = 12.8 kcal·mol<sup>-1</sup>; both vs. **12**<sup>OTf</sup>). In contrast to protonation with [HNMe<sub>3</sub>]<sup>+</sup>, these barriers are both below the energy of starting compound **1**, which makes the *Curtin-Hammett-principle* not applicable and explains the low selectivity upon protonation of **1** with triflic acid at r.t.

Scheme 61: Computed energy profile for proton induced N<sub>2</sub>-cleavage (*left branch*) and proton reduction (*right branch*) both *via* double protonation of **1** with triflic acid at 25 °C (black) and -80 °C (green). The italic energies represent the calculated barriers for N<sub>2</sub>-splitting from **13**<sup>OTf<sub>2</sub></sup> to give **11**<sup>OTf</sup>.

Lowering the temperature of protonation with HOTf to -80 °C perturbs this picture even further (Scheme 61, green). Compared to r.t. the preference of ligand protonated **12**<sup>OTf</sup> (ΔG<sub>193 K</sub><sup>o</sup> = -15.1 kcal·mol<sup>-1</sup>) over hydride **14** (ΔG<sub>193 K</sub><sup>o</sup> = -10.3 kcal·mol<sup>-1</sup>) is increased, due to both, stabilization of **12**<sup>OTf</sup> and destabilization of **14**, in line with the exclusive experimental observation of **12**<sup>OTf</sup> and **13**<sup>OTf<sub>2</sub></sup> upon single and double

## 2.2 Proton induced N<sub>2</sub>-cleavage *versus* proton reduction

---

protonation of **1** with HOTf at low temperatures. The free energy of doubly pincer protonated **13**<sup>OTf<sub>2</sub></sup> ( $\Delta G_{193\text{ K}}^{\circ} = -23.9 \text{ kcal}\cdot\text{mol}^{-1}$  vs. **1**) is much lower than the one of dihydrogen-complex **15** ( $\Delta G_{193\text{ K}}^{\circ} = 3.8 \text{ kcal}\cdot\text{mol}^{-1}$  vs. **1**), which is even higher than the calculated barrier for N<sub>2</sub>-cleavage ( $\Delta G_{\text{eff}}^{\ddagger} = -4.0 \text{ kcal}\cdot\text{mol}^{-1}$  vs. **1**). This results in selective N<sub>2</sub>-cleavage and formation of **11**<sup>OTf</sup> as it was experimentally observed.

Overall, these studies provide guidelines how the selectivity between competing proton- and nitrogen-reduction can be tuned. Both reactions proceed through different pathways, either *via* protonation of hydride-isomer (**14**), resulting in proton-reduction, or *via* (double) pincer-protonation, giving nitride **11**. The equilibrium between hydride **14** and pincer-protonated **12** can be shifted to the latter upon usage of hydrogen-bonding anions and low temperatures, overall favoring nitrogen-reduction. Furthermore, the pK<sub>a</sub> of the acid can have a kinetic effect on the selectivity. While upon usage of weak acids the selectivity is *Curtin-Hammett*-controlled, this control can be overcome upon usage of strong acids, which can result in different reaction outcomes.

### 2.3 N<sub>2</sub>-cleavage of [(N<sub>2</sub>){W(CO)(PNP)}<sub>2</sub>] (**4**)

In contrast to [(N<sub>2</sub>){WCl(PNP)}<sub>2</sub>] (**1**), its carbonyl-analogue [(N<sub>2</sub>){W(CO)(PNP)}<sub>2</sub>] (**4**) features two additional electrons within the {WNNW}- $\pi$ -manifold. As already described in chapter 2.1.2, this leads to a  $\{\pi^{10}\delta^4\}$ -configuration, which not only changes the degree of N<sub>2</sub>-activation, but also the reactivity of **4** with respect to N<sub>2</sub>-splitting. While **1** is thermally stable, **4** cleaves the NN-bond upon heating or irradiation to give the corresponding W(IV)-nitride, [W(N)(CO)(PNP)] (**16**) (Scheme 62). Both pathways have been examined in detail, which is described in the next two chapters.

Scheme 62: Thermal and photolytical N<sub>2</sub>-cleavage of **4** to give **16**.

The nitride product **16** is light-blue, diamagnetic and gives one singlet resonance flanked by tungsten satellites in the <sup>31</sup>P{<sup>1</sup>H} NMR spectrum ( $\delta_{\text{P}} = 104.5$  ppm). Starting from <sup>15</sup>N-labeled <sup>15</sup>N-**4** gives rise to <sup>15</sup>N-**16**, whose <sup>15</sup>N{<sup>1</sup>H} NMR spectrum reveals one singlet, flanked by tungsten satellites ( $\delta_{\text{N}} = 447.0$  ppm). The W $\equiv$ N stretch of solid **16** ( $\tilde{\nu}_{\text{WN}}(^{14}\text{N-16}) = 998 \text{ cm}^{-1}$ ,  $\tilde{\nu}_{\text{WN}}(^{15}\text{N-16}) = 973 \text{ cm}^{-1}$ ) was found in a similar range compared to the one of [W(N)Cl(<sup>H</sup>PNP)]<sup>+</sup> (**11**) and other related tungsten-nitrides.<sup>202–205</sup>

The carbonyl-stretching frequency of solid **16** as well as of its <sup>15</sup>N-labeled isotopomer <sup>15</sup>N-**16** was found at 1883 cm<sup>-1</sup> in the IR-spectrum, strongly shifted compared to dinuclear **4** ( $\tilde{\nu}_{\text{CO}}(\mathbf{4}) = 1785, 1741 \text{ cm}^{-1}$ ). This hypsochromic shift is attributed to weaker back-donation from the tungsten ions as a result of charge transfer from the metal to the N<sub>2</sub>-bridge upon cleavage, which shows, even though both the {WNNW}-core of **4** and the W $\equiv$ N-bond in **16** are highly covalent, a significant electron transfer to the N<sub>2</sub>-bridge upon cleavage.

Due to the good solubility in all tried solvents, no crystals suitable for X-ray diffraction could be obtained.

2.3.1 Thermal N<sub>2</sub>-cleavage

The thermal decay of **4** into **16** was monitored by <sup>1</sup>H NMR at different temperatures (75-105 °C). The concentration of **4** was determined using an internal standard and plotted *versus* time (Figure 25, triangles). Notably, the reaction terminates prior to full conversion, which implies an equilibrium between dinuclear **4** and nitride **16**, which is shifted to **16** at higher temperatures.

Figure 25: Plot of the concentration of **4** vs. time at different temperatures. The triangles represent the measured concentrations, while the blank lines represent the fitted curves.

The obtained kinetic data was fitted to a model with a first order splitting reaction ( $k_1$ ) and a reverse second order nitride coupling reaction ( $k_2$ ) according to the rate law shown in Scheme 63 (Figure 25, blank lines).

Scheme 63: The equilibrium of **4** and **16** and the resulting rate law for the decay of **4** used to fit the kinetic curves.

## 2.3 N<sub>2</sub>-cleavage of [(N<sub>2</sub>)<sub>2</sub>{W(CO)(PNP)}<sub>2</sub>] (**4**)

The rate constants  $k_1$  and  $k_2$  determine the equilibrium constant  $K$ , which was additionally determined by measuring the equilibrium concentrations of **4** and **16** after elongated heating of **4** to 75, 85 and 95 °C, respectively (Figure 26, right, blue squares). *Van't Hoff*-analysis (Figure 26, left) with the so-obtained values gave rise to the thermodynamic parameters of the reaction, which show that N<sub>2</sub>-cleavage is endothermic ( $\Delta H_{\text{exp}}^{\circ} = 10.9 \pm 0.7 \text{ kcal}\cdot\text{mol}^{-1}$ ), but entropically driven at high temperatures ( $\Delta S_{\text{exp}}^{\circ} = 24.8 \pm 1.8 \text{ cal}\cdot\text{mol}^{-1}\cdot\text{K}^{-1}$ ).<sup>208</sup>

*Eyring*-analysis (Figure 26, right) of the rate constant  $k_1$  offered the activation parameters for N<sub>2</sub>-cleavage ( $\Delta H_{\text{exp}}^{\ddagger} = 30.1 \pm 0.9 \text{ kcal}\cdot\text{mol}^{-1}$ ,  $\Delta S_{\text{exp}}^{\ddagger} = 2.3 \pm 0.4 \text{ cal}\cdot\text{mol}^{-1}\cdot\text{K}^{-1}$ ). The high barrier is in line with the stability of **4** at r.t. and also inhibits reverse nitride-coupling at low temperatures. Accordingly, to overcome the kinetic barrier high temperatures are required, which also shift the equilibrium towards entropically favored **16**. This system represents the first example of a reversible N<sub>2</sub>-splitting/ nitride-coupling reaction. This holds the promise that the formed nitride species is less "overstabilized" and more reactive towards reagents that are more compatible with reductive conditions. The functionalization of **16** will be discussed in chapter 2.4.

Figure 26: left:  $\ln(K)$  vs.  $1/T$  -plot for the conversion of **4** into **16**. The black dots represent the  $K$ -values obtained by kinetic modeling, while the blue dots are the directly determined  $K$ -values. right:  $\ln(k_1/T)$  vs.  $1/T$  -plot for the conversion of **4** into **16**.

The experimental results are supported by computational investigations.<sup>9</sup> As already mentioned, the triplet ground state (**T4**) is favored over the closed-shell-singlet ground state (**S4**) by  $1.2 \text{ kcal}\cdot\text{mol}^{-1}$ , while no open-shell-singlet could be found. Additionally, two different isomers of nitride **16**, which differ with respect to the conformation of the ligand backbone, could be identified (Figure 27). The conformation of the ligand-backbone within **16a** is similar to dinuclear **4**, while the backbone of **16b** is flipped (Figure 27, right). Both isomers are separated by  $\Delta G_{298 \text{ K}}^{\circ} = 6.0 \text{ kcal}\cdot\text{mol}^{-1}$ , with **16b** being the favored.

<sup>9</sup> DFT-calculations were performed by Prof. Dr. Vera Krewald and M.Sc. Severine Rupp using: PBE/def2-TZVP,def2-SVP.

### 2.3 N<sub>2</sub>-cleavage of [(N<sub>2</sub>)<sub>2</sub>{W(CO)(PNP)}<sub>2</sub>] (**4**)

Figure 27: *left*: Computed structures of **16a**. *middle*: Computed structures of **16b**. *right*: Overall of the computed structures of **16a** (orange) and **16b** (blue). For clarity all hydrogen-atoms were omitted.

Starting from **T4**, N<sub>2</sub>-cleavage into directly dissociated **16a** was calculated to be slightly endergonic ( $\Delta G_{298\text{K}}^{\circ} = 5.3 \text{ kcal}\cdot\text{mol}^{-1}$ ). Additional driving force ( $6.0 \text{ kcal}\cdot\text{mol}^{-1}$ ) is added by isomerization of **16a** into **16b** after cleavage. Overall, the computed value for cleavage of **4** into **16b** ( $\Delta G_{298\text{K}}^{\circ} = -0.7 \text{ kcal}\cdot\text{mol}^{-1}$ .) compares well to the experimentally derived value ( $\Delta G_{\text{exp}}^{\circ} = 3.5 \pm 0.9 \text{ kcal}\cdot\text{mol}^{-1}$ , Scheme 64, *left*). The small difference may arise from additional stabilization of **T4** by spin-orbit coupling, which is not sufficiently expressed by the DFT computations.

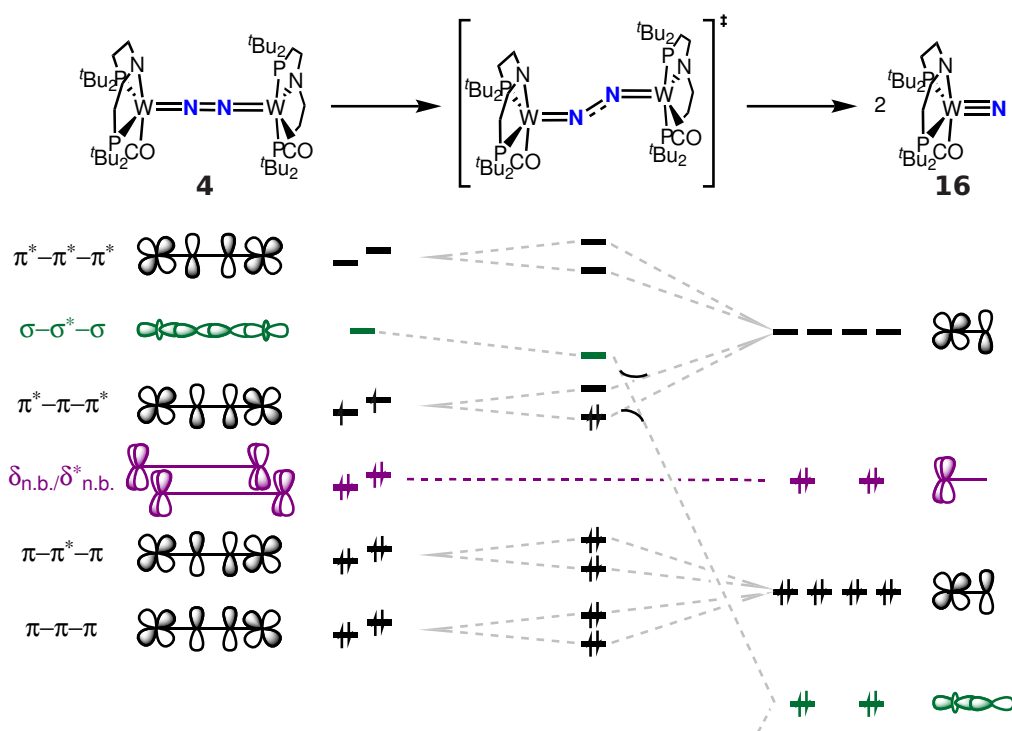

Scheme 64: *left*: Energy-profile for the N<sub>2</sub>-splitting of **4** to give **16** including the experimental and computed values. *right*: Structure of the calculated singlet-transition-state, **S\*TS**.

## 2.3 N<sub>2</sub>-cleavage of [(N<sub>2</sub>){W(CO)(PNP)}<sub>2</sub>] (**4**)

The lowest transition-state for N<sub>2</sub>-cleavage without isomerization of the ligand backbone (**<sup>5</sup>TS**) features a closed-shell singlet-configuration and was localized 39.5 kcal·mol<sup>-1</sup> above **T4** (Scheme 64, *right*), which is significantly higher than the experimentally derived value ( $\Delta G_{\text{exp}}^{\ddagger} = 29.4 \pm 0.1$  kcal·mol<sup>-1</sup>). The transition-state on the triplet-surface (**<sup>T</sup>TS**) is 19.4 kcal·mol<sup>-1</sup> above **<sup>5</sup>TS**.

Preliminary computational results indicate that conformational changes of the ligand backbone prior to N<sub>2</sub>-cleavage decrease the kinetic barrier for NN-bond scission and bring the energies of the respective transition states closer to the experimentally derived value. The lowest transition state including these conformational changes of the ligand backbone is calculated to be singlet-configured, which can be accounted to bending of the {WNNW}-core (Scheme 65). Due to the lower symmetry of this *zig-zag*-conformation, the degeneracy of the  $\pi^*-\pi-\pi^*$ -orbitals is lifted. As a result spin-pairing to a singlet-conformation becomes favorable, as already described for analogous systems.<sup>15,60,70</sup>

Scheme 65: Qualitative molecular orbital diagram for the splitting of **4** into **16** via a *zig-zag*-transition state.

### 2.3 N<sub>2</sub>-cleavage of [(N<sub>2</sub>)<sub>2</sub>{W(CO)(PNP)}<sub>2</sub>] (**4**)

---

Compared to the isostructural and isoelectronic ReCl-congener **XII** ( $\Delta G_{\text{exp}}^{\ddagger} = 19.8 \pm 1.3 \text{ kcal}\cdot\text{mol}^{-1}$ ;  $\Delta G_{\text{calc}}^{\circ} = -40.3 \text{ kcal}\cdot\text{mol}^{-1}$ ),<sup>36</sup> splitting of **4** into **16** is both kinetically and thermodynamically less favored, which can be attributed to the strong  $\pi$ -acceptor properties of the carbonyl-ligand. As already described in the introduction (chapter 1.2.2), N<sub>2</sub>-cleavage proceeds *via* electron transfer from the  $\pi^*-\pi-\pi^*$  into the former  $\sigma-\sigma^*-\sigma$ -orbital, which drops in energy and forms the M-N  $\sigma$ -orbital within the generated nitride-species (Scheme 65). Accordingly, the relative energies of these orbitals should correlate to the thermodynamic and kinetic parameters of the reaction.

The presence of a strong  $\pi$ -accepting ligand, such as CO, should lead to stabilization of the  $\pi^*-\pi-\pi^*$ -orbitals and a larger energy gap to the  $\sigma-\sigma^*-\sigma$ -orbital. Hence, mixing of these orbitals reduced, which results in a higher kinetic barrier for N<sub>2</sub>-cleavage for **4** compared to **XII**.

Furthermore, breakage of the NN-bond in **4** is accompanied by a significant amount of charge transfer from the {MNNM}- $\pi$ -manifold to the N<sub>2</sub>-ligand, as indicated by a strong hypsochromic shift of the carbonyl-stretching frequencies ( $\Delta\tilde{\nu}_{\text{CO}}(\mathbf{4}\rightarrow\mathbf{16}) = 120 \text{ cm}^{-1}$ ,<sup>h</sup> Scheme 62) upon cleavage. Compared to **XII** the electron density within the {MNNM}- $\pi$ -core of **4** is decreased by back-bonding to the carbonyl-ligands. Transfer of electron density from the  $\pi$ -manifold to the nitrogen should therefore be thermodynamically less favorable, in line with the different thermodynamic driving forces for **4** and **XII**.<sup>36</sup>

---

<sup>h</sup> The average of both CO-stretching frequencies in **4** was used.

### 2.3.2 Photolytic N<sub>2</sub>-cleavage

Besides the described thermal pathway, **16** can also be obtained *via* photolysis. Irradiation of **4** in benzene at 427 nm (LED,  $\Delta\lambda = 10$  nm) for 8 h gives **16** quantitatively with a quantum yield of  $\phi_{427\text{ nm}} = 0.37 \pm 0.03\%$ . The UVvis spectrum of **4** is depicted in Figure 28 and features two intense bands at 343 ( $\epsilon = 27000 \text{ L}\cdot\text{mol}^{-1}\cdot\text{cm}^{-1}$ ) and 395 nm ( $\epsilon = 28000 \text{ L}\cdot\text{mol}^{-1}\cdot\text{cm}^{-1}$ ) and another intense isolated band at 511 nm ( $\epsilon = 21200 \text{ L}\cdot\text{mol}^{-1}\cdot\text{cm}^{-1}$ ). Upon wavelength selective photolysis of **4**, using a Xe-arc lamp with cut-off filters, the selective region for photolytical N<sub>2</sub>-cleavage was determined to 395-590 nm. Usage of longer wavelengths showed no reaction, while usage of shorter wavelengths lead to substantial amounts of unidentified side-products, which were tentatively attributed to W-N<sub>2</sub> bond cleavage as reported for related systems.<sup>61,133,136</sup>

However, photolysis of **4** at  $\lambda > 305$  nm under <sup>15</sup>N<sub>2</sub>-atmosphere does not lead to <sup>15</sup>N incorporation into the nitride photoproduct **16**, indicating that the W-N bond might be photostable. Instead, photolysis of **16** at  $\lambda > 305$  nm resulted in formation of undefined products, which can be associated to CO-loss of the nitride product under these conditions.

Figure 28: Experimental UVvis spectrum of **4** in THF.

### 2.3 N<sub>2</sub>-cleavage of [(N<sub>2</sub>)<sub>2</sub>{W(CO)(PNP)}<sub>2</sub>] (**4**)

For further insight, the photochemical and photophysical properties of **4** were examined *via* UVvis/UVvis pump-probe transient absorption spectroscopy.<sup>i</sup> For all used pump wavelengths within the productive window (440, 475, 511, 530 nm) no features of an electronically excited state could be detected. Instead all transient difference spectra directly after excitation show bleaching in the band centers and enhanced absorption at the low energy sides of the ground state absorption spectrum (Figure 29, *left*), which is a typical signature of a vibrationally hot electronic ground state formed within the temporal resolution of the experiment ( $\tau_{\text{exc}} \approx 70 \pm 20$  fs). Thermal cooling occurs within 60 ps and results in almost full relaxation, in line with the low quantum yield for N<sub>2</sub>-cleavage.

Usage of shorter pump wavelengths (330 and 380 nm) lead to slow decomposition into undefined products, in agreement with steady state photolysis.

Figure 29: *left*: Transient UVvis difference spectra of **4** in THF at selected pump-probe delays (pump wavelength: 475 nm). The black line shows the scaled linear absorption spectrum. *right*: Time-dependence of the integrated absolute absorption changes (red line is a bi-exponential fit with  $\tau_1 = 1.5 \pm 0.2$  ps and  $\tau_2 = 9.2 \pm 0.5$  ps).

By analysing the integral over the absolute value of the difference spectra ( $|\Delta A(E)|$ ) integrated over the whole measured spectral range the relaxation dynamics of the ground state were quantified (Figure 29, *right*). Using a bi-exponential decay the time dependence could be fitted, which gave rise to two time constants (relative amplitudes) of  $\tau_1 = 1.5 \pm 0.2$  ps (54%) and  $\tau_2 = 9.2 \pm 0.5$  ps (46%).

While the slower component ( $\tau_2$ ) is a typical value for vibrational energy transfer of a vibrationally highly excited molecule to a solvent, the faster component ( $\tau_1$ ) can be attributed to intramolecular vibrational redistribution (IVR), which implies a non-statistical energy distribution directly after relaxation from the excited state created by preferential population of those vibrational modes which couple to the electronic transition. Within the timescale of  $\tau_1 = 1.5$  ps the energy is redistributed over the whole molecule to establish a quasi-equilibrium of the internal energy.

<sup>i</sup> The pump-probe experiments were run and analyzed by Prof. Dr. Dirk Schwarzer and M.Sc. Jan-Hendrik Bortler.

### 2.3 N<sub>2</sub>-cleavage of [(N<sub>2</sub>)<sub>2</sub>W(CO)(PNP)]<sub>2</sub> (**4**)

Since the carbonyl stretching vibrations represent excellent IR-probes, the photochemistry of **4** was also examined by UVvis/IR pump-probe transient absorption spectroscopy (Figure 30, 400 nm pump pulse). As for the UVvis/UVvis pump-probe transient absorption measurements no features of an electronically excited state could be detected, which is in line with the poorer time resolution of the UVvis/IR pump-probe transient absorption measurements. The transient difference spectra directly after excitation (Figure 30) show bleaching in the band centers and an increased absorption at the high energy sides of the ground state absorption spectrum, which is again a typical signature of a vibrationally hot electronic ground state and supports the observations made in the UVvis/UVvis pump-probe transient absorption measurements.

Figure 30: Transient IR difference spectra of **4** in THF at selected pump-probe delays (pump wavelength: 400 nm).

Overall, these observations indicate three characteristics of this system. First, the lifetime of the excited state is shorter than the time-resolution of the experiment ( $70 \pm 20$  fs). Second, the energy directly after relaxation to the electronic ground state is non-statistically distributed and requires another 1.5 ps to reach quasi-equilibrium. Finally, all photoreactivity has to occur within a timescale of 60 ps, since afterwards the molecule has completely relaxed.

Taking these considerations into account, two scenarios are envisioned, a diabatic pathway (Figure 31, *left*) and a hot-ground-state pathway (Figure 31, *right*). An adiabatic pathway, where the reaction proceeds on the energy-surface of the excited state, would require longer lifetimes of the excited state and can therefore be excluded.<sup>209,210</sup>

### 2.3 N<sub>2</sub>-cleavage of [(N<sub>2</sub>)<sub>2</sub>{W(CO)(PNP)}<sub>2</sub>] (**4**)

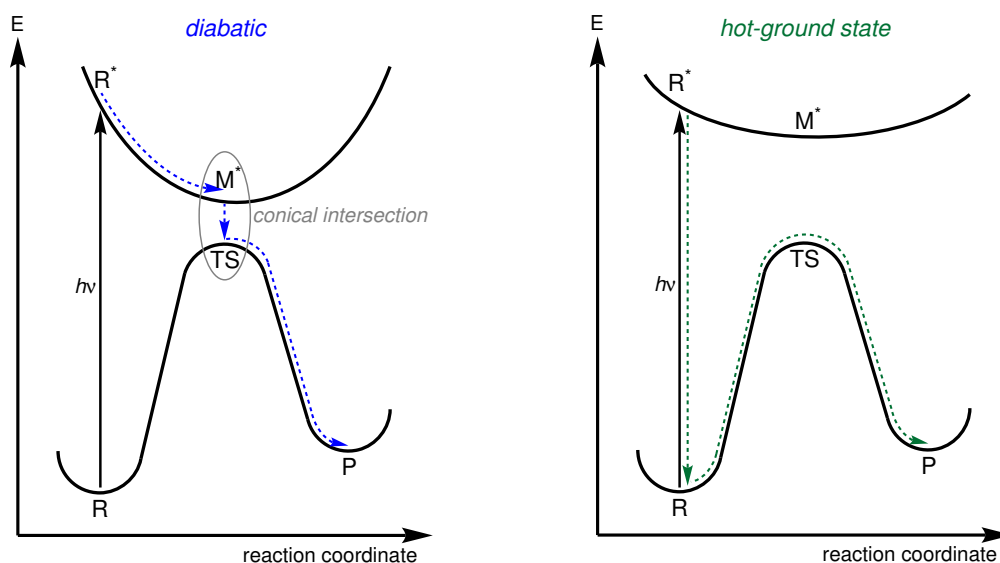

Figure 31: Simplified energy surfaces for a diabatic photoreaction (*left*) and a reaction proceeding *via* a hot-ground state (*right*) with R = reactant, TS = transition state, P = product, M\* = minimum of the energy surface of the excited state.<sup>209,210</sup>

In case of a diabatic photoreaction, strong coupling of the ground- and excited-state energy surfaces is required. At a certain geometry along the reaction coordinate between the reactant (R) and the product (P) both energy-surfaces converge, which allows energetically favorable irradiationless "jumps" from the excited-state to the ground-state surface. In a simplified picture (Figure 31, *left*), following a representative point, irradiation leads to vertical excitation of the reactant from the ground- into the excited state surface ( $R \xrightarrow{h\nu} R^*$ ), followed by relaxation towards the energetic minimum of the excited state ( $R^* \rightarrow M^*$ ). At a certain geometry, it is possible for the representative point to fall back to the ground-state energy-surface. If this jump proceeds prior to the transition state (TS) the molecule relaxes back into R, without any product formation. Crossing beyond the transition state results in relaxation to the minimum of product P.<sup>209,210</sup>

In case of a hot-ground-state reaction (Figure 31, *right*), the molecule relaxes directly after excitation back to the ground-state surface. The energy of the absorbed photon is distributed over the molecule by population of higher vibrational states. If the absorbed energy is large enough, dissociative modes can also be populated, which can induce bond-breakage and product formation.<sup>209,210</sup>

To estimate if such a hot-ground-state pathway is possible, the internal energy of the molecule after excitation and IVR was calculated and compared with the derived kinetic barrier for N<sub>2</sub>-cleavage. The DFT-calculated vibrational frequencies of **4** were used to determine its internal vibrational energy at r.t. ( $E_{\text{r.t.}} = 15700 \text{ cm}^{-1}$ ). Addition of a 400 nm photon leads to an internal vibrational energy of  $E_{\text{exc}} = 40700 \text{ cm}^{-1}$ , which corresponds to an internal vibrational temperature of  $T \approx 500 \text{ K}$ .

### 2.3 N<sub>2</sub>-cleavage of [(N<sub>2</sub>)<sub>2</sub>{W(CO)(PNP)}<sub>2</sub>] (**4**)

---

According to eqn. 2.5, this value, together with the experimentally derived activation parameters ( $\Delta H_{\text{exp}}^{\ddagger} = 30.1 \pm 0.9 \text{ kcal}\cdot\text{mol}^{-1}$ ,  $\Delta S_{\text{exp}}^{\ddagger} = 2.3 \pm 0.4 \text{ cal}\cdot\text{mol}^{-1}\cdot\text{K}^{-1}$ ), gives rise to the rate constant  $k_{\text{splitt}}$  for unimolecular splitting, which is too small to compete with rapid cooling ( $\tau_2 = 9.2 \pm 0.5 \text{ ps}$ ).<sup>211</sup>

$$k_{\text{splitt}} = \frac{k_b \cdot T}{h} \cdot \exp\left(-\frac{\Delta H^{\ddagger} - T \cdot \Delta S^{\ddagger}}{R \cdot T}\right) = 2.3 \text{ s}^{-1} \quad (2.5)$$

In consequence, N<sub>2</sub>-splitting from a hot-ground state after statistical energy-distribution is not feasible. However, the smaller time constant ( $\tau_1 = 1.5 \text{ ps}$ ) indicates a non-statistical energy distribution directly after relaxation to the hot-ground-state. Vibronic coupling of the electronically excited state with, for example, bending-modes of the {MNNM}-core *en route* to a *zig-zag*-transition state, might decrease the kinetic barrier for NN-bond scission. Such vibronic coupling has been observed by *Cummins* and *Blank* for [(N<sub>2</sub>)<sub>2</sub>{Mo(N(<sup>t</sup>Bu)Ar)<sub>3</sub>}<sub>2</sub>] (**1**; Ar = 3,5-C<sub>6</sub>H<sub>3</sub>Me<sub>2</sub>) as an underdamped oscillation in the pump-probe decay, which was assigned to vibronic coupling of a bending mode of the {MoNNMo}-core.<sup>136</sup>

By now, no direct indication for coupling of a productive vibrational mode to the electronic excitation could be found for **4**, which might indicate that N<sub>2</sub>-cleavage proceeds *via* direct population or rapid internal conversion into an N–N dissociative state.

For further insights into the nature of the excited state, the photochemistry of **4** was examined computationally using TD-DFT.<sup>j</sup> The experimentally obtained UVvis spectrum of **4** is well reproduced by TD-DFT calculations for both electronic configurations, triplet (**T4**) and closed-shell singlet (**S4**), but with a blue-shift of 0.38 eV in both cases (Figure 32).

---

<sup>j</sup> TD-DFT calculations were performed by **Prof. Dr. Vera Krewald** and **M.Sc. Severine Rupp** using: PBE0(THF).

### 2.3 N<sub>2</sub>-cleavage of [(N<sub>2</sub>)<sub>2</sub>{W(CO)(PNP)}<sub>2</sub>] (**4**)

Figure 32: Comparison of the experimental (black) and TD-DFT computed (blue:  $S = 0$ ; red:  $S = 1$ ) electronic absorption spectra of **4**. The inset shows the potentially active transitions.

To distinguish which of the calculated transitions within the photolytical active window (395-590 nm) are the actually productive ones for N<sub>2</sub>-cleavage, **4** was photolyzed with wavelengths longer than 530 nm. Although, some conversion could be observed, the rate was significantly slower compared to irradiation with shorter wavelengths, which indicates that the productive transition is energetically slightly above 530 nm (or 2.72 eV/456 nm in the calculated spectrum). Therefore, T13/T14 (both 2.89 eV/429 nm (calc.)) or S15/S16 (both 2.51 eV/494 nm (calc.)) are assumed as the productive transitions for photolytic N<sub>2</sub>-cleavage in **4**.

The difference density plots of all these four transitions reveal {W-CO} → N<sub>2</sub>-character (Figure 33, *left*), which can be rationalized as an metal-to-ligand charge transfer (MLCT) from the metal-carbonyl centered  $\delta/\delta^*$ -orbitals to the  $\pi^*-\pi^*-\pi^*$ -orbitals within the {WNNW}-core (Figure 33, *right*). Due to its all anti-bonding character population of this orbital should decrease the bond-orders within the {M-N-N-M}-core and therefore increase its flexibility. In this way, bending to a *zig-zag*-conformation might be induced, which finally leads to cleavage of the NN-bond.

## 2.3 N<sub>2</sub>-cleavage of [(N<sub>2</sub>)<sub>2</sub>{W(CO)(PNP)}<sub>2</sub>] (**4**)

Figure 33: *left*: Difference density plots (loss in yellow, gain in red) for the transitions S15, S16, T13 and T14 calculated for **4**. *right*: Simplified MO-scheme for **4** with the electronic excitation assigned to productive in photolytic N<sub>2</sub>-cleavage.

Overall, the TD-DFT calculations imply a photochemical pathway in which N<sub>2</sub>-cleavage proceeds *via* direct population or rapid internal conversion into an N–N dissociative state. Population of the  $\pi^*-\pi^*-\pi^*$ -orbitals leads to bending of the {W–N–N–W}-core, which should lower the  $\sigma-\sigma^*-\sigma$ -orbital in energy. In consequence, mixing between the  $\pi^*-\pi-\pi^*$ - and  $\sigma-\sigma^*-\sigma$ -orbitals is enabled, which finally leads to cleavage of the NN-bond. Nevertheless, a final assignment is currently prevented by the rapid timescales and low quantum yields.

However, a  $\delta/\delta^* \rightarrow \pi^*-\pi^*-\pi^*$ -excitation with MLCT-character was also found to be productive for N<sub>2</sub>-cleavage within **XIII** and might therefore hint to a general feature for photolytic N<sub>2</sub>-cleavage from an idealized fourfold symmetry.<sup>71</sup> In contrast, the active transition within *Cummins'* **I** was assigned to a  $\pi-\pi^*-\pi \rightarrow \pi^*-\pi-\pi^*$ -transition, which should strengthen the NN-bond and might explain the different photochemistry of **I** compared to **4**.<sup>136</sup>

## 2.4 Functionalization of tungsten-nitrido-complexes

As described in the previous chapters, two different tungsten-nitrido-complexes,  $[W(N)Cl(^H\text{PNP})]^+$  (**11**) and  $[W(N)CO(\text{PNP})]$  (**16**), could be obtained *via*  $N_2$ -cleavage from **1** and **4**, respectively. However, comparison of their thermodynamic driving forces for  $N_2$ -cleavage shows, that splitting of **17** into **11** upon protonation is strongly downhill. Accordingly, **11** should be largely overstabilized and more difficult to functionalize. In contrast, splitting of **4** into **16** is almost thermoneutral, rendering the nitride product more reactive based on thermodynamic arguments. Additionally, synthetic access to **16** *via* photolysis is much more convenient and does not compete with any other side reaction. Therefore, further functionalization attempts focused on **16**.

### 2.4.1 Alternative synthesis of $[W(N)(CO)(\text{PNP})]$ (**16**) *via* an azide route<sup>k</sup>

Since the synthesis of  $[W(N)(CO)(\text{PNP})]$  (**16**) *via* the  $N_2$ -splitting route requires several reaction steps with moderate overall yields, alternative synthetic pathways to generate **16** have been developed in cooperation with the group of *Caulton*, which will be described in this chapter (Scheme 66).

Refluxing a mixture of  $[W(CO)_6]$  with  $^H\text{PNP}$  in toluene or acetonitrile gives  $[W(CO)_3(^H\text{PNP})]$  (**9**) in good yields. The diamagnetic compound shows a singlet signal in the  $^{31}\text{P}\{^1\text{H}\}$  NMR spectrum at 89.5 ppm flanked by tungsten satellites. The  $^1\text{H}$  NMR spectrum shows two resonances for the  $^t\text{Bu}$ -groups and four signals for the ligand CH-protons, indicating  $C_s$ -symmetry, due to the presence of the NH-proton, which was assigned to a signal at 2.53 ppm based on a cross-peak in the  $^1\text{H}$ - $^{15}\text{N}$  HSQC NMR spectrum. The IR spectrum of solid **9** shows a band at  $3227\text{ cm}^{-1}$  that was assigned to the N-H-stretch and three intense bands at 1896, 1773 and  $1753\text{ cm}^{-1}$  assigned to the three carbonyl-ligands, similar to other  $W(0)$ -triscarbonyl-complexes.<sup>212</sup> The molecular structure obtained by X-ray diffraction shows that the  $^H\text{PNP}$ -ligand is coordinated in a meridional fashion, most likely due to the steric bulk of the  $^t\text{Bu}$ -substituents (Figure 34, *left*).

## 2.4 Functionalization of tungsten-nitrido-complexes

Scheme 66: The two possible synthetic pathways for the synthesis of **16**.

**9** can be oxidized and deprotonated in one step using *N*-iodosuccinimide to give deep purple  $[\text{W}(\text{CO})_2(\text{PNP})]$  (**18**) in almost quantitative yield. Notably, the *N*-halosuccinimides can also be used to generate the corresponding chloro- and bromo-analogues of **18**. However, only the iodo-complex **18** was feasible for anion exchange reactions, most likely due to the better leaving group character of iodide compared to chloride and bromide.

Figure 34: Molecular structures of **9** (left) and **18** (right) in the crystal obtained by single crystal X-ray diffraction. Hydrogen-atoms are omitted for clarity. Selected bond lengths [ $\text{\AA}$ ] and angles [ $^\circ$ ] for **9**: W1-C21 1.990(3), W1-C22 1.928(3), W1-C23 1.999(3), W1-N1 2.344(2), W1-P1 2.5058(7), W1-P2 2.4944(7); C21-W1-C23 154.79(13), N1-W1-C22 169.19(11), P1-W1-P2 154.04(2). Selected bond lengths [ $\text{\AA}$ ] and angles [ $^\circ$ ] for **18**: W1-C21 1.920(4)/1.973(15), W1-C22 2.000(4)/1.971(16), W1-I1 2.8256(4)/2.831(6), W1-N1 2.008(3)/2.062(4), W1-P1 2.5246(9)/2.564(3), W1-P2 2.5307(8)/2.522(3); C21-W1-I1 134.87(11)/141.9(13), C22-W1-N1 148.05(14)/160.2(17), P1-W1-P2 150.91(3)/148.34(15).

## 2.4 Functionalization of tungsten-nitrido-complexes

In the  $^{31}\text{P}\{^1\text{H}\}$  NMR spectrum of **18** a singlet resonance flanked by tungsten-satellites was found at 67.6 ppm. The  $^1\text{H}$  NMR spectrum features two signals corresponding to the  $^t\text{Bu}$ -groups and four signals for the ligand backbone, indicating  $C_5$ -symmetry with the iodo substituent *trans* to one carbonyl-ligand, which was confirmed by the molecular structure obtained by X-ray diffraction (Figure 34, *right*). In the IR spectrum of solid **18** two carbonyl stretching vibrations at 1907 and 1799  $\text{cm}^{-1}$  could be observed. The absence of an N-H stretch in the IR as well as of an NH-proton in the  $^1\text{H}$  NMR together with the planarity of the PNP-nitrogen evidences the deprotonation of the PNP-ligand. As an effect of stronger  $\sigma$ - and  $\pi$ -donation of the amide compared to the amine ligand the W-N distance decreases from 2.344(2) Å (in **9**) to 2.008(3) Å (in **18**).

Salt metathesis of **18** with  $[\text{nBu}_4\text{N}]\text{N}_3$  gives  $[\text{W}(\text{N}_3)(\text{CO})_2(\text{PNP})]$  (**19**) in almost quantitative yield. The NMR spectroscopic features are similar to the ones for **18** and show a singlet flanked by tungsten satellites in the  $^{31}\text{P}\{^1\text{H}\}$  NMR spectrum at 77.7 ppm, two signals for the  $^t\text{Bu}$ -groups and four signals for the ligand backbone in the  $^1\text{H}$  NMR spectrum. The IR spectrum of solid **19** features two nearly unchanged carbonyl stretching vibrations at 1907 and 1828  $\text{cm}^{-1}$ , while the band for the azide stretching vibration was found at 2072  $\text{cm}^{-1}$ . The molecular structure of **19** derived by X-ray diffraction also closely reassembles the structure of **18**. **19** is thermally unstable and releases  $\text{N}_2$  and CO upon heating to 65 °C to give nitride **16**. However, the reaction is not quantitative due to the formation of one major side product, which was identified as  $[\text{W}(\text{NCO})(\text{CO})_2(\text{PNP})]$  (**21**). The selective synthesis of **21** will be described later in this chapter.

Therefore, alternative ways to trigger  $\text{N}_2$ -loss from **19** were investigated. Mild acids, such as lutidinium-salts, lead to clean formation of ligand protonated, cationic  $[\text{W}(\text{N})(\text{CO})(^{\text{H}}\text{PNP})]^+$  (**20**) in good yields (Scheme 67).

Scheme 67: Protonation of **19** liberates CO and  $\text{N}_2$  and gives **20**.

The  $^1\text{H}$  NMR spectrum of **20** displays two signals for the  $^t\text{Bu}$ -groups, four multiplets for the ligand backbone and one signal at 5.93 ppm attributed the NH-proton. In the  $^{31}\text{P}\{^1\text{H}\}$  NMR spectrum one singlet at 93.1 ppm was detected. Alternatively, **20** can also be synthesized upon protonation of **16** with lutidinium-salts, giving identical NMR signature. An  $^{15}\text{N}$ -labeled sample ( $^{15}\text{N}$ -**16**) derived *via* the  $\text{N}_2$ -splitting route, gave rise to a resonance in the  $^{15}\text{N}\{^1\text{H}\}$  NMR spectrum at 445.7 ppm. The IR spectrum of solid

**20** shows a sharp, intense band for the carbonyl ligand at  $1928\text{ cm}^{-1}$ . Compared to neutral **16**, this band is shifted at about  $45\text{ cm}^{-1}$  to higher wavenumbers, which can be attributed to the reduced donor properties of the amine ligand. The  $\text{W}\equiv\text{N}$ -stretch was found at  $1048\text{ cm}^{-1}$  ( $\tilde{\nu}_{\text{WN}}$  ( $^{15}\text{N}$ -**20**) =  $1014\text{ cm}^{-1}$ ) close to the  $\text{W}\equiv\text{N}$ -stretch of **11** ( $\tilde{\nu}_{\text{WN}}$  ( $^{14}\text{N}$ -**11**) =  $1058\text{ cm}^{-1}$ ) and other, related tungsten-nitrides.<sup>202–205</sup> The N-H-stretching vibration was detected at  $3118\text{ cm}^{-1}$ .

Figure 35: Molecular structure of **20** in the crystal obtained by single crystal X-ray diffraction. Hydrogen-atoms, with exception of H111, and co-crystallized solvent molecules are omitted for clarity. Selected bond lengths [ $\text{\AA}$ ] and angles [ $^\circ$ ]: W1-C21 2.005(2), W1-N1 2.2402(17), W1-N2 1.6861(18), W1-P1 2.4886(5), W1-P2 2.5006(5); C21-W1-N1 162.75(8), N1-W1-N2 103.59(8), P1-W1-P2 153.504(18).

In the solid state **20** is isostructural with the previously described **11** (Figure 35) and features a square pyramidally coordinated tungsten atom ( $\tau=0.15$ )<sup>193</sup> with the nitride ligand in the apical position and a short  $\text{W}\equiv\text{N}$ -distance (1.6861(18)  $\text{\AA}$ ). The triflate anion is hydrogen bonded to the NH-proton of the ligand backbone, which was found in the residual density map and isotropically refined. Due to the lack of  $\pi$  backdonation of the amine ligand, the distance between the tungsten ion and the PNP-ligand-nitrogen is relatively long (2.2402(17)  $\text{\AA}$ ).

Finally, **20** can be deprotonated with weakly coordinating bases like, NaHMDS or KHMDS, to give quantitatively the splitting product **16**, which was then used for further functionalization.

### 2.4.2 Functionalization of [W(N)(CO)(PNP)] (**16**) using $\pi$ -acceptor ligands

As already mentioned, the thermal transformation of [W(N<sub>3</sub>)(CO)<sub>2</sub>(PNP)] (**19**) into [W(N)(CO)(PNP)] (**16**) is not quantitative due to the formation of one side-product. Within this reaction besides one equivalent of N<sub>2</sub> one equivalent of CO is liberated, which is known to couple with nitride-moieties to cyanate in some cases (see chapter 1.3.3). Therefore the reactivity of **16** with CO was examined.

Addition of CO to **16** results in the almost quantitative formation of deep purple [(PNP)W(NCO)(CO)<sub>2</sub>] (**21**) (Scheme 68). Alternatively, **21** was also synthesized *via* salt-metathesis of **18** with [nBu<sub>4</sub>N][OCN] in isolated yields up to 80%. The NMR signature of **21** is similar to those of **18** or **19**, respectively, and features one singlet in the <sup>31</sup>P{<sup>1</sup>H} NMR spectrum at 76.7 ppm, two signals for the <sup>t</sup>Bu-groups and four signals for the ligand backbone in the <sup>1</sup>H NMR spectrum.

Scheme 68: Carbonylation of **16** leads to formation of **21**.

Carbonylation of a <sup>15</sup>N-labeled sample of **16** gives rise to <sup>15</sup>N-**21**, whose <sup>15</sup>N{<sup>1</sup>H} NMR spectrum features a triplet (<sup>2</sup>J<sub>NP</sub> = 2.6 Hz) at -347 ppm, flanked by tungsten-satellites indicating N-coordination of the NCO-ligand. Accordingly, the <sup>31</sup>P{<sup>1</sup>H} NMR spectrum of <sup>15</sup>N-**21** shows a doublet. Furthermore, the broad signal at 145 ppm in the <sup>13</sup>C{<sup>1</sup>H} NMR of unlabeled **21** assigned to the NCO-ligand sharpens upon <sup>15</sup>N-labeling to a doublet (<sup>1</sup>J<sub>CN</sub> = 33.8 Hz) (Figure 36).

In the IR spectrum of solid **21**, the carbonyl-stretching vibrations appear at 1910 and 1831 cm<sup>-1</sup>. The intense sharp band at 2203 cm<sup>-1</sup> is assigned to the NCO-ligand and shifts upon <sup>15</sup>N-labeling ( $\tilde{\nu}_{\text{NCO}}(^{15}\text{N-21}) = 2197 \text{ cm}^{-1}$ ). In the solid state (Figure 37), the molecular structure of **21** derived by X-ray diffraction closely reassembles the structures of **18** and **19**.

## 2.4 Functionalization of tungsten-nitrido-complexes

Figure 36: NMR signature of  $^{15}\text{N}$ -**21**. *left*:  $^{13}\text{C}\{^1\text{H}\}$  NMR signal of the  $^{15}\text{NCO}^-$  and  $^{14}\text{NCO}$ -ligand. *right*:  $^{15}\text{N}\{^1\text{H}\}$  and  $^{31}\text{P}\{^1\text{H}\}$  NMR signals of  $^{15}\text{N}$ -**21**.

Importantly, the described spectroscopic features of **21** are the same as for the observed side-product in the formation of **16** upon heating of **19**. Therefore, the formation of the side product from reaction of **19** to **16** can be explained by the liberation of CO, which readily reacts with **16**.

Figure 37: Molecular structure of **21** in the crystal obtained by single crystal X-ray diffraction. Hydrogen atoms were omitted for clarity. Selected bond lengths [Å] and angles [°]: W1-C21 1.964(4), W1-C22 2.028(4), W1-N1 2.011(3), W1-N2 2.116(3), W1-P1 2.5030(10), W1-P2 2.5077(10); C21-W1-C22 77.03(16), C21-W1-N1 85.54(15), C22-W1-N1 153.31(14), N1-W1-N2 122.56(13), P1-W1-P2 155.09(3).

2.4.3 Mechanistic investigations on CN-bond coupling<sup>1</sup>

To elucidate whether the CN-bond formation occurs *intramolecularly* via insertion of the nitride-nitrogen into the W-CO bond or *intermolecularly* via nucleophilic attack of the nitride on the incoming carbonyl-ligand, **16** was carbonylated with <sup>13</sup>CO. Depending on the mechanism, this should result in the formation of different products (Scheme 69), either showing an unaffected NCO- and two <sup>13</sup>CO-ligands (*intramolecular*, **21a**) or one N<sup>13</sup>CO-ligand with one <sup>12</sup>CO- and one <sup>13</sup>CO-ligand (*intermolecular*, **21b**).

Scheme 69: Possible pathways for the formation of **21** via carbonylation of **16**, either following an intramolecular (*left*) or an intermolecular (*right*) pathway for C-N coupling to give **21a** or **21b**, respectively.

The <sup>13</sup>C{<sup>1</sup>H} NMR spectrum of the obtained <sup>13</sup>CO-labeled product clearly displays an increased intensity of the resonances assigned to the two carbonyl-ligands at 266 and 262 ppm, while the intensity of the NCO-ligand at 145 ppm is unaffected compared to unlabeled **21** (Figure 38), indicating the incorporation of two <sup>13</sup>CO ligands into the formed complex, which was further supported LIFDI-MS. Both carbonyl-resonances give multiplets due to coupling with the two P-atoms of the PNP-ligand as well as coupling with each other. The signal in the <sup>31</sup>P{<sup>1</sup>H} NMR spectrum gives a doublet of doublets (<sup>2</sup>J<sub>CP</sub> = 8.4, 4.3 Hz), also implying coordination of two <sup>13</sup>CO-ligands to the tungsten center (Figure 38). Consequently, in the IR spectrum the NCO-stretch is unaffected, while both carbonyl-stretches are bathochromically shifted ( $\tilde{\nu}_{\text{CO}}(^{13}\text{CO-21}) = 1860, 1762 \text{ cm}^{-1}$ ). These findings proof the formation of **21a** via an intramolecular pathway, similar to the one proposed by *Liddle* (Scheme 48).<sup>188</sup>

<sup>1</sup> Parts of this work have been published in: J. Schneider "Synthese und Funktionalisierung von Wolfram-PNP-Nitrid Komplexen" *Bachelor Thesis*, Georg-August Universität Göttingen, **2019**.

## 2.4 Functionalization of tungsten-nitrido-complexes

Figure 38: NMR signature of  $^{13}\text{CO-21}$ . *left:*  $^{31}\text{P}\{^1\text{H}\}$  NMR spectrum. *right:*  $^{13}\text{C}\{^1\text{H}\}$  NMR spectrum, the inlays show a zoom into the signals of the two carbonyl ligands.

Since such a reactivity does not necessarily require the addition of CO, **16** was also functionalized using other ligands. Addition of two equivalents of isocyanide (CN-R, R =  $t\text{Bu}$ ,  $\text{C}_6\text{H}_4\text{OMe}$ ) to **16** yields in the formation of  $[\text{W}(\text{NCO})(\text{CN-R})_2(\text{PNP})]$  (R =  $t\text{Bu}$  (**22**),  $\text{C}_6\text{H}_4\text{OMe}$  (**23**)), in line with an intramolecular CN coupling reaction (Scheme 70). Other potential ligands, such as pyridine or trimethylphosphine, showed no reaction with **16**, which might be due to their slightly higher steric encumbrance.

Scheme 70: Functionalization of **16** using isocyanides.

The formation of  $\text{NCO}^-$  in **22** and **23** was proven *via*  $^{13}\text{C}\{^1\text{H}\}$  NMR, which features in both cases a broad signal at 143 ppm very close to the signal assigned to the NCO-ligand in **21**. Furthermore, the IR spectra of solid **22** and **23** both show a intense sharp band at  $2203\text{ cm}^{-1}$  identical with the NCO-stretch observed in **21**. Finally, the formation of a cyanate ligand could be confirmed by X-ray diffraction (Figure 39).

Figure 39: Molecular structures of **22** (left) and **23** (right) in the crystal obtained by single crystal X-ray diffraction. Hydrogen atoms and cocrystallized solvent molecules were omitted for clarity. Selected bond lengths [Å] and angles [°] for **22**: W1-C21 2.014(8), W1-C26 2.035(8), W1-N1 2.028(11), W1-N4 2.102(13), W1-P1 2.4906(18), W1-P2 2.4533(19); C21-W1-N4 153.4(4), C26-W1-N1 156.6(4), P1-W1-P2 155.23(7). Selected bond lengths [Å] and angles [°] for **23**: W1-C22 2.020(2), W1-C30 2.000(2), W1-N1 2.020(2), W1-N2 2.118(2), W1-P1 2.4735(6), W1-P2 2.4960(6); C22-W1-N1 155.95(9), C30-W1-N1 155.48(9), P1-W1-P2 155.36(2).

These intramolecular CN-coupling reactions contrast with the nucleophilic attack of the nitride to CO, which was proposed by *Cummins* for Na[V(N)(N<sup>t</sup>Bu)Ar<sub>3</sub>] (**LXXXIX**) (Scheme 47).<sup>186</sup> The differences might account from the different d-electron counts of both compounds. *Cummins'* vanadium(V)-nitride exhibits a d<sup>0</sup>-configuration, which might, together with the steric encumbrance of the supporting ligands, circumvent binding of a carbonyl-ligand to the metal. In case of **16**, the tungsten ion is d<sup>2</sup>-configured and the carbonyl-ligand is already coordinated, which might explain the different mechanism. Nevertheless, the formation of **21** represents, after *Kawaguchi's* N<sub>2</sub>-derived V(V)-nitride [V(N)(ONO)]<sup>-</sup> (**XCVIIIc**), the second example for CN-coupling of an N<sub>2</sub>-derived nitride with CO.<sup>190</sup>

#### 2.4.4 Liberation of cyanate and closure of the synthetic cycle

In the previous chapters the cleavage of  $N_2$  and the formation of cyanate *via* C-N-coupling with CO to give  $[W(NCO)(CO)_2(PNP)]$  (**21**) has been discussed. This chapter will focus on the release of the formed cyanate and closure of the synthetic cycle.

First, abstraction of the formed  $NCO^-$  *via* reduction, attempting direct reformation of  $N_2$ -bridged **4** was probed. For this purpose the redox chemistry of **21** was studied *via* cyclic voltammetry (CV). The cyclic voltammogram shows an irreversible reduction event at a potential of -2.0 V (vs.  $Fc^+/Fc$  in THF). The reduction product shows an irreversible oxidative wave at -1.55 V (vs.  $Fc^+/Fc$  in THF), which was not observed without prior reduction of **21** (Figure 40).

Figure 40: Cyclic voltammogram (100 mV/s, THF, Ar) of the reduction of **21**, showing the first cycle in blue and the second cycle in red. The green trace shows the oxidation of **24** measured independently.

Chemical reduction of **21** with one equiv. NaHg results in incomplete conversion of the starting material and formation of one new diamagnetic species. Usage of two equivalents of reductant gives rise to full conversion to this diamagnetic species, which was identified as anionic  $[W(CO)_2(PNP)]^-$  (**24**) both under Ar or  $N_2$ . In a similar way, bright orange **24** can also be synthesized *via* reduction of **18** with 2 equiv. of NaHg or upon deprotonation of **9** with strong bases such as NaHMDS (Scheme 71).

## 2.4 Functionalization of tungsten-nitrido-complexes

Scheme 71: Formation of **24** *via* reduction of **18** or **21** or *via* deprotonation of **9**.

In the solid state, **24** features a square pyramidally coordinated tungsten ion with one carbonyl ligand in the apical site ( $\tau_5 = 0.15$ , Figure 41).<sup>193</sup> However, in solution on the NMR timescale **24** appears  $C_{2v}$ -symmetric as indicated by only one signal for two carbonyl ligands in the  $^{13}\text{C}\{^1\text{H}\}$  NMR spectrum as well as the presence of only one resonance for the <sup>t</sup>Bu-groups and two signals for the methylene protons of the ligand backbone in the  $^1\text{H}$  NMR spectrum.

Figure 41: Molecular structure of **24** in the crystal obtained by single crystal X-ray diffraction. Selected bond lengths [Å] and angles [°]: W1-C21 1.902(9), W1-C22 1.911(8), W1-N1 2.088(6), W1-P1 2.426(2), W1-P2 2.4484(19); C21-W1-C22 87.7(3), C21-W1-N1 124.3(3), C22-W1-N1 148.0(3), P1-W1-P2 156.74(6).

Both carbonyl ligands are strongly activated as indicated by the long CO- and the short WC-distances as well as the very low CO-stretching frequencies found in the IR-spectrum of solid **24**. This higher degree of activation of the carbonyl ligands is attributed to the lower oxidation-state of the tungsten ion compared to the other discussed biscarbonyl complexes (Table 7).

## 2.4 Functionalization of tungsten-nitrido-complexes

Table 7: Comparison of the spectroscopic and structural parameters of the synthesized tungsten(II)-biscarbonyl-complexes ( $[WX(CO)_2(PNP)]$ ) with the tungsten(0)-biscarbonyl-complex (**24**).

X =	<b>18</b> I <sup>-</sup>	<b>10</b> Cl <sup>-</sup>	<b>19</b> N <sub>3</sub> <sup>-</sup>	<b>21</b> NCO <sup>-</sup>	<b>24</b> -
Oxidation-State	+II	+II	+II	+II	0
d <sub>W-CO</sub> [Å]	1.920(4) 2.000(4)	1.939(8) 2.013(6)	1.943(4) 2.001(4)	1.964(4) 2.028(4)	1.902(9) 1.911(8)
d <sub>C-O</sub> [Å]	1.169(4) 1.158(5)	1.104(9) 1.159(10)	1.169(4) 1.167(5)	1.153(5) 1.151(5)	1.206(10) 1.205(9)
$\tilde{\nu}_{CO}$ [cm <sup>-1</sup> ]	1907 1799	1914 1815	1907 1828	1909 1831	1677 1604

The cyclic voltammogram of **24** shows a reversible oxidation wave at -1.55 V (vs. Fc<sup>+</sup>/Fc in THF), which is identical to the new formed oxidation wave monitored in the CV of **21** indicating that the reduction of **21** results in the formation of **24** also on the CV-timescale (Figure 40, *green*). Nevertheless, it remains unclear, why the observed oxidative wave in case of **21** appears irreversible even at higher scan-rates (1000 mV/s). One explanation could be a decreased stability of the oxidation product in the presence of NCO<sup>-</sup>, which could be proven by CV-measurements of **24** in the presence of a suitable NCO<sup>-</sup>-source.

Overall, reductive abstraction of the cyanate-ligand does not lead to N<sub>2</sub>-binding and/or reformation of **4**, therefore other strategies for cyanate-abstraction and closure of the synthetic cycle have been probed.

Addition of TMS-Cl to **21** yields TMS-NCO and  $[WCl(CO)_2(PNP)]$  (**10**, Scheme 72), both in quantitative yield. Similar to its iodo-congener **18**, **10** can also be synthesized upon oxidation of **9** with NCS (NCS = *N*-chlorosuccinimide). The structural and spectroscopic features of **10** are very similar to the other tungsten(II)-biscarbonyl-species (**18**, **19**, **21**) described earlier (Figure 42). Notably, no reaction was observed upon addition of [PPN]Cl or benzyl chloride to **21** even at elevated temperatures.

Scheme 72: Liberation of NCO from **21** via salt-metathesis with TMS-Cl giving **10** and TMS-NCO in quantitative yields.

Figure 42: Molecular structure of **10** in the crystal obtained by single crystal X-ray diffraction. Selected bond lengths [Å] and angles [°]: W1-C21 1.939(8), W1-C22 2.056(8), W1-N1 2.013(6), W1-Cl1 2.4682(19), W1-P1 2.5175(19), W1-P2 2.516(2); C21-W1-C22 73.0(3), C21-W1-N1 89.2(3), C22-W1-N1 152.9(3), N1-W1-Cl1 122.32(18), P1-W1-P2 155.24(6).

The formation of TMS-NCO was confirmed upon comparison of the NMR-features with an original sample. Additionally, the  $^{15}\text{N}\{^1\text{H}\}$  NMR signal of TMS- $^{15}\text{NCO}$ , which was synthesized from  $^{15}\text{N}$ -**21**, was detected at -346 ppm. The  $^{29}\text{Si}\{^1\text{H}\}$  NMR of the formed TMS-NCO features a singlet at 4.5 ppm, which becomes a doublet ( $^1J_{\text{SiN}} = 14.2$  Hz) upon  $^{15}\text{N}$ -labeling, proving Si-N-bond formation.

The formation of **10** holds the promise of reforming either  $[(\text{N}_2)\{\text{WCl}(\text{PNP})\}_2]$  (**1**) or  $[(\text{N}_2)\{\text{WCl}(\text{CO})(\text{PNP})\}_2]$  (**8**), upon abstraction of at least one carbonyl ligand per tungsten and binding of  $\text{N}_2$ . Release of a carbonyl-ligand using a CO-abstracting agent, such as  $\text{Me}_3\text{N-O}$  or  $\text{C}_5\text{H}_5\text{N-O}$ , was unsuccessful and showed no reaction, even under  $\text{N}_2$ -atmosphere, elevated temperatures and/or photolysis ( $\lambda > 305$  nm). Therefore the oxidation of **10** was performed with *N*-chlorosuccinimide (NCS) as both oxidant and chloride donor in order to reform  $[\text{WCl}_3(\text{PNP})]$  (**5**), which can finally be reduced to give  $\text{N}_2$ -bridged **1**.

While there was no reaction of **10** with two equiv. of NCS at r.t., heating of the reaction mixture lead to decomposition to unidentified, insoluble products and only traces (<5%) of **5**. However, upon photolysis of **10** with NCS at r.t. the yield in **5** could be increased to 30% (Scheme 73). In this way a synthetic cycle for the formation of  $\text{NCO}^-$  from  $\text{N}_2$  and CO could be closed (Scheme 74). Similar to *Kawaguchi's* **XCVIII**, the only other system capable for this transformation, the requirement of both reductant (NaHg) and oxidant (NCS) prevents catalytic turnover under a chemical redox regime.<sup>190</sup>

## 2.4 Functionalization of tungsten-nitrido-complexes

Scheme 73: Oxidation of **10** under photolytic conditions with NCS (*N*-chlorosuccinimide) reforms **5**.

In summary, carbonylation of  $N_2$ -derived **16** results in formation of **21** in nearly quantitative yield.  $^{13}C$ -labeling revealed an intramolecular CN-bond formation *via* formal insertion of the nitride-nitrogen into the W-CO bond. The formed cyanate-ligand can be abstracted either *via* reduction or quantitatively *via* salt-metathesis using TMS-Cl (Scheme 74).

Abstraction of the carbonyl ligands requires the addition of a strong oxidant and UV-light and gives only moderate yields, which also prevents catalytic reactivity. Nevertheless, this system represents the second example for the transformation of  $N_2$  and CO into cyanate using a terminal nitrido-complex.

Scheme 74: Synthetic cycle for the formation of TMS-NCO from  $N_2$  and CO using a W(PNP)-platform.

## 2.5 Summary and Outlook<sup>m</sup>

In summary, a series of four isostructural N<sub>2</sub>-bridged ditungsten compounds was successfully synthesized and characterized. The derived structural and spectroscopic parameters fully corroborate the proposed bonding-scheme for such idealized D<sub>4h</sub>-symmetric molecules (Scheme 75). Accordingly, oxidation of {π<sup>8</sup>δ<sup>4</sup>}-configured [(N<sub>2</sub>){WCl(PNP)}<sub>2</sub>] (**1**) is metal centered without any significant impact on the degree of N<sub>2</sub>-activation. A significantly smaller degree of N<sub>2</sub>-activation was observed for **4**, which can be rationalized by two additional electrons within the {WNNM}-core populating the π\*-π-π\*-orbitals.

Scheme 75: Comparison of the electronic structures of **3**, **2**, **1** and **4**.

The comparison of **1** with its Mo-analogue **XI** reveals a slightly weaker activated bridging N<sub>2</sub> ligand for the 5d-metal-complex, which was rationalized by weaker backbonding. Nevertheless, both compounds are stable with respect to N<sub>2</sub>-cleavage, underlining the requirement of ten π-electrons within the {MNNM}-core. Compared to **XI**, the oxidation potentials of **1** are cathodically shifted, marking it as the better reductant, which effects the reactivity upon protonation.<sup>70</sup>

## 2.5 Summary and Outlook

While protonation of **XI** leads, independent of acid and temperature, to N<sub>2</sub>-cleavage,<sup>70</sup> protonation of **1** can also result in proton-reduction and oxidation of **1** (Scheme 76), which was rationalized by an equilibrium between ligand-protonated **12** and hydride **14**. Similar to **XI**, protonation of both PNP-pincer units in **1** results in N<sub>2</sub>-cleavage and formation of nitride **11**. In contrast, protonation of the hydride-isomer **14** results in H<sub>2</sub>-evolution and oxidation of the tungsten-ions. The equilibrium between **12** and **14** can be modulated by the choice of acid and temperature, with strong, hydrogen-bonding acids and low temperatures favoring ligand-protonation and therefore N<sub>2</sub>-cleavage.

Scheme 76: Protonation of **1** leads either to N<sub>2</sub>-cleavage and formation of **11** or to proton-reduction and formation of **3**.

In contrast to its isoelectronic ReCl-congener **XII**, **4** is stable at r.t., which was attributed to the  $\pi$ -accepting properties of the carbonyl-ligands, which stabilize the  $\pi^*-\pi-\pi^*$ -orbitals in energy and thereby increase the kinetic barrier for N<sub>2</sub>-cleavage (Scheme 77). Furthermore, due to mixing of the CO-ligand with the {WNNW}- $\pi$ -manifold electron transfer from the  $\pi$ -system to the bridging N<sub>2</sub>-ligand upon cleavage becomes less favorable, which leads to a slightly endergonic splitting reaction and represents the first example for an equilibrium between N<sub>2</sub>-cleavage and reverse nitride-coupling.

Scheme 77: The experimentally derived kinetic and thermodynamic parameters for N<sub>2</sub>-cleavage in **4** yielding **16**.

## 2.5 Summary and Outlook

---

Quantitative N<sub>2</sub>-splitting can be achieved *via* photolysis ( $\lambda = 395\text{-}590\text{ nm}$ ). The productive transitions feature  $\delta/\delta^* \rightarrow \pi^*-\pi^*-\pi^*$ -character, similar to **XIII**.<sup>71</sup> Population of this all-antibonding orbital within the {W-N-N-W}-core might increase the flexibility and induce bending to a *zig-zag*-conformation, which finally leads to N<sub>2</sub>-cleavage. Examination of the photochemical and photophysical properties of **4** *via* UVvis/UVvis and UVvis/IR transient spectroscopies revealed that the lifetime of the excited state is shorter than the temporal resolution of the experiment ( $\tau_{\text{exc}} \approx 70 \pm 20\text{ fs}$ ). Directly after relaxation to the electronic ground state, the energy is non-statistically distributed, which might facilitate N<sub>2</sub>-cleavage. However, vibronic coupling of the electronically excited state with bending-modes of the {WNNW}-core, as observed by *Cummins* and *Blank* for **1** as an underdamped oscillation in the pump-probe decay,<sup>136</sup> could not be detected. Once the pump-energy is statistically distributed ( $\tau_1 = 1.5 \pm 0.2\text{ ps}$ ) the internal temperature of **4** is too low to show thermal reactivity. Due to the very fast timescales and the poor quantum yields a final assignment, whether N<sub>2</sub>-cleavage follows a diabatic pathway or proceeds from an vibrationally hot-ground-state with a non-statistical energy distribution, cannot be made yet and relies on further examinations.

The obtained splitting product **16** was successfully functionalized with CO to give cyanate-complex **21** in nearly quantitative yield. <sup>13</sup>CO-labeling studies revealed an intramolecular pathway, in which the CN-bond is formed *via* insertion of the nitride-nitrogen into the tungsten-carbonyl-bond. Even though such a mechanism has already been suggested,<sup>188</sup> these current studies reveal the first direct experimental evidence for such a pathway.

Full *N*-atom-transfer can be achieved upon either reduction of **21** to give **24** or upon salt-metathesis using TMS-Cl, which forms TMS-NCO and **10** in quantitative yield. The latter can be oxidized with NCS, which also serves as a chloride-source, under photolytic conditions to give **5** and closes the synthetic cycle (Scheme 78). Besides *Kawaguchi's* {V(ONO)}-platform (**XCVIII**, Scheme 50), the presented {W(PNP)}-system represents the second example for N<sub>2</sub>-derived nitride-CO-coupling and full *N*-atom-transfer.<sup>190</sup>

## 2.5 Summary and Outlook

Scheme 78: Synthetic cycle for the formation of TMS-NCO from  $N_2$  and CO using a W(PNP)-platform.

The established {W(PNP)}-platform can be used for further investigations. So far, the reactivity of dinuclear **1**, with respect to  $N_2$ -cleavage, has only been examined with Brønsted acids. An intriguing question would be the use of Lewis-acids in order to cancel out the interaction of the pincer-amide-p-orbitals with the {WNNW}- $\pi$ -manifold, which should lead to  $N_2$ -cleavage and (depending on the Lewis-acid) direct formation of the respective tungsten(V)-nitride, [W(N)Cl(PNP)] (**25**), without the drawback of competing proton-reduction.

Scheme 79: Proposed Lewis-acid induced  $N_2$ -cleavage of **1**.

## 2.5 Summary and Outlook

---

Although a series of four isostructural N<sub>2</sub>-bridged ditungsten compounds was successfully synthesized and characterized, a compound with a { $\pi^9\delta^4$ }-configuration is not included. Such a compound would fill the gap between { $\pi^8\delta^4$ }-configured **1** and { $\pi^{10}\delta^4$ }-configured **4** and would, due to its  $S = 1/2$  magnetic ground state, allow deeper investigations of the electronic structure. Preliminary electrochemical studies of **4** indicated that such a species might be accessible by oxidation of **4**.

In that respect, the replacement of the carbonyl-ligands in **4** by other neutral ligands might give insights into the influence of the auxiliary ligands on the degree of N<sub>2</sub>-activation and stability with respect to N<sub>2</sub>-cleavage. Furthermore, the photolytic active transition for N<sub>2</sub>-cleavage in **4** was identified as a {M-CO} → N<sub>2</sub>-transition, which will shift upon replacement of the CO-ligand. This shift could be correlated to the ligand-strength and provide some guidelines for the design of future systems capable for photolytic N<sub>2</sub>-cleavage.

Regarding N<sub>2</sub>-functionalization, the access *via* photolytic N<sub>2</sub>-cleavage, using visible light, makes **16** an attractive platform. Besides the already mentioned reagents (CO and CN-R), there are still potential candidates for nitride-functionalization, including benzoyl- and alkyl-halides or O-atom transfer agents, such as mCBPA (mCBPA = 3-chloroperbenzoic acid) or *N*-oxides.

The electrophilicity of the nitride-moiety could be increased upon oxidation of **16**. Preliminary attempts were always accompanied by the formation of substantial amounts of ligand-protonated [W(N)(CO)(<sup>H</sup>PNP)]<sup>+</sup> (**20**), whose presence complicated the isolation and characterization of other potential products, but also revealed an increased reactivity of the potentially formed W(V)-product, which might be useful for further functionalization attempts.

---

## 3 Experimental

### 3.1 General Working Techniques

All experiments were carried out under inert atmosphere (Ar or N<sub>2</sub>, both 5.0, Linde gas) using standard Schlenk and glove-box techniques, unless otherwise noted. Purification of CO gas (Air Liquide, 99.997%) was obtained by passing the gas through a steel coil cooled to -78 °C. <sup>13</sup>CO (Eurisotop GmbH, 99.30% <sup>13</sup>C) and <sup>15</sup>N<sub>2</sub> (Sigma Aldrich, 98% <sup>15</sup>N) were used as purchased without further purification.

All glassware was cleaned in KOH/*iso*-propanol baths, neutralized in HCl baths, washed with deionized water and dried at 120 °C. Prior to use, all vessels were evacuated at a Schlenk line with periodically applied heating. Small scale reactions (≤ 10 mg) were typically performed in J-Young NMR tubes.

Unless otherwise noted all solvents were purchased in HPLC quality (Merck) and used as obtained from an MBraun Solvent Purification System. THF and toluene were further purified by stirring over Na/K-alloy for several days, PhCl was dried over CaH<sub>2</sub>. Deuterated solvents were obtained from Eurisotop GmbH and dried by stirring over Na/K-alloy (THF-*d*<sub>8</sub>, C<sub>6</sub>D<sub>6</sub>, Tol-*d*<sub>8</sub>) or CaH<sub>2</sub> (CD<sub>2</sub>Cl<sub>2</sub>, CD<sub>3</sub>CN). NEt<sub>3</sub> was dried over KOH and CaH<sub>2</sub>, whereas W(CO)<sub>6</sub>, *N*-chlorosuccinimide and Fc were sublimed prior usage. TMS-Cl and TMS-NCO were distilled and degased. Celite and Silica gel 60 silanized were heated over 150 °C under vacuum for several days prior usage. All other chemicals were used as purchased without further purification.

<sup>H</sup>PNP,<sup>213</sup> [H(OEt<sub>2</sub>)<sub>2</sub>][BAR<sub>24</sub><sup>F</sup>],<sup>214</sup> [H(OEt<sub>2</sub>)<sub>2</sub>][Al(OC(CF<sub>3</sub>)<sub>3</sub>)<sub>4</sub>],<sup>215</sup> Ag[BPh<sub>4</sub>],<sup>216</sup> FcOTf,<sup>217</sup> [LutH]OTf,<sup>217</sup> [PPN]N<sub>3</sub><sup>218,219</sup> and [PPN][NCO]<sup>218,219</sup> were synthesized according to literature procedures.

### 3.2 Analytical Methods

#### 3.2.1 Crystallographic details

Suitable single crystals for X-ray structure determination were selected from the mother liquor under an inert gas atmosphere and transferred in protective perfluoro polyether oil on a microscope slide. The selected and mounted crystals were transferred to the cold gas stream on the diffractometer. The diffraction data were obtained at 100 K on a Bruker D8 three-circle diffractometer, equipped with a Photon 100 CMOS detector and an Incoatec microfocus source with Quazar mirror optics (Mo-K $\alpha$  radiation,  $\lambda = 0.71073$  Å). The data obtained were integrated with SAINT and a semi-empirical absorption correction from equivalents with SADABS was applied. The structures were solved and refined using the Bruker SHELX 2014 software package.<sup>220–223</sup> All non-hydrogen atoms were refined with anisotropic displacement pa-

rameters. All C-H hydrogen atoms were refined isotropically on calculated positions by using a riding model with their  $U_{\text{iso}}$  values constrained to 1.5  $U_{\text{eq}}$  of their pivot atoms for terminal  $\text{sp}^3$  carbon atoms and 1.2 times for all other atoms.

### 3.2.2 Cyclic voltammetry

All electrochemical data were recorded on a Metrohm PGSTAT101 using the Nova 2.0 software. The cyclic voltammetry (CV) data were recorded either in a UVvis cell or a three neck cell equipped with a glassy carbon ( $\varnothing = 1.6$  mm) working electrode (WE), a Pt-wire counter electrode (CE) and a Ag wire pseudo-reference electrode (RE). Referencing was performed against the  $\text{Fc} / \text{Fc}^+$  couple. All experiments were performed under Ar in 0.1 M  $[\text{nBu}_4\text{N}][\text{PF}_6]$  in THF.

During the second half of this thesis, CV data were compensated for internal resistance ( $iR$ ). In these cases, the scan rate dependence of the peak currents  $i_p$  was analyzed according to the *Randles-Sevcik* equation:

$$i_p = 0.446nFAC^0 \left( \frac{nFvD_0}{RT} \right)^{1/2} \quad (3.6)$$

where  $n$  is the number of transferred electrons,  $F$  is the *Faraday's* constant,  $A$  is the electrode surface in  $\text{cm}^2$ ,  $C^0$  is the bulk concentration of the analyte in  $\text{mol}\cdot\text{cm}^{-3}$ ,  $v$  is the scan rate in  $\text{V}\cdot\text{s}^{-1}$  and  $D_0$  is the diffusion coefficient of the oxidized species in  $\text{cm}^2\cdot\text{s}^{-1}$ .<sup>224</sup> This equation is valid for freely diffusing, non absorbed analyte in solution which undergoes fast, electrochemically reversible electron transfer. Thus deviations from linearity of a plot of  $i_p$  vs.  $v^{1/2}$  can indicate quasi-reversible electron transfer (accompanied by a scan rate dependent peak-to-peak separation) or absorption of the analyte on the electrode surface (which should have a constant peak-to-peak separation).

### 3.2.3 Electron Paramagnetic Resonance

Experimental X-band EPR spectra were recorded on a Bruker ELEXSYS-II E500 CW-EPR. Simulations were carried out using the program QPOW, as modified by *J. Telser*.<sup>225</sup>

### 3.2.4 Elemental Analysis

Elemental analysis were obtained from the Analytical Laboratories at the Georg-August-University Göttingen using an Elementar Vario EL 3 analyzer.

### 3.2.5 Head Space Analysis

The  $\text{H}_2$  was detected by a Shimadzu GC-2014 gas chromatograph equipped with a TCD detector and a ShinCarbon ST 80/100 Silco column.

### 3.2.6 Irradiation

All photolysis experiments were performed using either a Kessil PR160-427 LED (427 nm) or a 150 W Hg(Xe) arc lamp with lamp housing and arc lamp power supply from LOT-Quantum Design GmbH. For the latter, IR radiation was eliminated by use of a water filter and photolyzed samples were kept at r.t. by a water bath.

### 3.2.7 Magnetic measurements

Magnetic moments were determined by Evans' method as modified by Sur and corrected for diamagnetic contributions.<sup>226</sup>

Magnetic susceptibility measurements were performed with a Quantum Design MPMS-XL-5 SQUID magnetometer in the temperature range from 295 to 2 K at 0.5 T applied field. The powdered sample was contained in a Teflon bucket and fixed in a non-magnetic sample holder. Each raw data point for the measured magnetic moment of the sample was corrected for the diamagnetic contribution by subtraction of the experimentally determined magnetic measurement of the Teflon bucket. The molar susceptibility data were corrected for the diamagnetic contribution using the Pascal constants and the increment method according to Haberditzel.<sup>227,228</sup> Experimental data were modelled with the julX program.<sup>229</sup>

### 3.2.8 Mass spectrometry

HR-ESI-MS (Bruker maXis QTOF) and LIFDI-MS (JEOL AccuTOF JMS-T100GCV) spectra were measured by the Zentrale Massenabteilung, Fakultät für Chemie, Georg-August-Universität Göttingen.

### 3.2.9 Nuclear magnetic resonance

NMR spectra were recorded on Bruker Avance III 300 or Avance III 400 spectrometers or an Avance 500 spectrometer with a Prodigy broadband cryoprobe, respectively, and calibrated to the residual solvent signals ( $C_6D_6$ :  $\delta_H = 7.16$  ppm,  $\delta_C = 128.4$  ppm; THF- $d_8$ :  $\delta_H = 3.58$  ppm,  $\delta_C = 67.6$  ppm).<sup>230</sup>  $^{31}P$ ,  $^{29}Si$  and  $^{15}N$  NMR chemical shifts are reported relative to external phosphoric acid, tetramethyl silan and nitromethane ( $\delta = 0.0$  ppm), respectively. Signal multiplicities are abbreviated as: s (singlet), d (doublet), triplet (t), m (multiplet), br (broad).

### 3.2.10 Quantum yield determination

The quantum yield for the photochemical splitting reaction of **4** into **16** was determined for photolysis with a 427 nm LED lamp. The lamps photon flux was determined prior to the experiment using a Thorlabs S120VC, 200-1100 nm photodiode, which was placed in 20 cm distance to the lamp and photolyzed with 25% power output to:

$$I = 6.5977 \cdot 10^{-7} \pm 1.3 \cdot 10^{-12} \text{ mol cm}^{-2} \text{ min}^{-1} \quad (3.7)$$

For the quantum yield determination, a solution of complex **4** in THF (2 mL,  $5.1 \cdot 10^{-5} \text{ mol} \cdot \text{L}^{-1}$ ) was irradiated with the same setup (same distance and output power from the LED lamp) for a total of 30 min. After every 2 min, the irradiation was stopped and the concentration of **4** was determined by monitoring of the absorbance at  $\lambda = 512 \text{ nm}$ . The quantum yield was determined by:

$$\phi = \frac{\Delta n_{t_x - t_{(x-1)}}}{n_{\text{Photons}, 2 \text{ min}} \cdot (1 - 10^{-A_{427 \text{ nm}}})} \quad (3.8)$$

Where  $\Delta n_{t_x - t_{(x-1)}}$  is the amount of **4** decomposed between two measurements, i.e. by irradiating for 2 min,  $n_{\text{Photons}, 2 \text{ min}}$  is the amount of photons reaching the sample during 2 minutes ( $2.6391 \cdot 10^{-6} \text{ mol}$  in the above described set-up, calculated by  $n = I \cdot t \cdot a$ ) and  $A_{427 \text{ nm}}$  is the absorbance of the solution at 427 nm at the beginning of each photolysis step. This results in a quantum yield of  $0.37 \pm 0.03\%$ .

Figure 43: Quantum yield determination of the photosplitting of **4** by 427 nm LED lamp. a) Decay of **4** during photolysis. b) Concentration profile of **4** during the reaction. c) Quantum yields between each irradiation interval.

### 3.2.11 Transient UVvis spectra

The transient UVvis-pump-probe setup described in ref<sup>231</sup> was updated with a new laser system (Solstice Ace, spectra physics) It includes a regenerative amplifier seeded by a diode pumped Ti:Sapphire seed laser (Mai Tai SP, spectra physics) and pumped by a diode pumped Nd:YLF-laser (Ascend 40, spectra physics). The significantly shorter 35 fs pulses at 800 nm central wavelength produce a mean output power of ~5 W at a repetition rate of 1 kHz.

A small percentage (about 3  $\mu$ J) was passing a translational stage (M-415.DG, Physik Instrumente) of 16.5 cm delay path for up to ~1.1 ns pump-probe-delay after transmitting a high reflective mirror ( $R \approx 99.9\%$ ) and focused on a 4 mm CaF<sub>2</sub> crystal generating a white light continuum as probe beam. A semi-transparent mirror split the beam into reference and probe which were focused onto their individual 256-element linear diode array mounted on a spectrograph (spectral window: 350-730 nm). The latter was passing a far UV quartz cuvette (Starna, optical path: 2 mm, transmission: 170-2700 nm) containing the sample (0.12-0.17 mM in THF) stirred by a magnet in order to refresh it between pulses.

The pump beam containing the residual output can now be prepared for wavelengths 240 nm–2.6  $\mu$ m using an automated optical parametric amplifier (TOPAS Prime+, light conversion, spectra physics) and subsequent frequency mixer (NirUVis, light conversion, spectra physics). The resulting beam was attenuated by an iris (0.3-1.0  $\mu$ J), passed a perforated rotating wheel cutting every second pulse for subtraction of spectra without pump excitation and rotated in polarization to 54.7° (magic angle) relative to probe for elimination of molecular rotational effects and focused into the sample and spatially overlapping with the probe beam. Both sample in solution and pure solvent transient spectra were measured at pre-programmed pump-probe-delays. Baseline, wavelength dependent temporal shifts due to group velocity dispersion of the probe beam and solvent transient spectra were corrected.

### 3.2.12 Transient IR spectra

A libra laser system (coherent) is the basis for the transient IR-pump-probe-setup. A Ti:Sapphire oscillator is pumped by a diode-pumped Nd:YAG laser (Evolution 30, coherent) and seeded laser (Vitesse, coherent) consisting of a diode-pumped, frequency doubled Nd:YVO<sub>4</sub> laser (Verdi, coherent) pumping a Ti:Sapphire laser head (VPUF e. g. Verdi pumped ultrafast laser head, coherent). A regenerative amplifier with compressor/stretcher unit is included. The output beam pulsing an 800 nm central wavelength at 1 kHz repetition rate possessed a temporal puls width of about 150 fs and a mean energy of 0.7 mJ. A semi-transparent mirror split the power 60:40.

About 60% served as input for an optical parametric amplifier with subsequent difference frequency generation of idler and signal as described in ref<sup>232</sup> producing an IR-probe-spectrum of 50-150 cm<sup>-1</sup> spectral width depending on the wavelength region. Another semi-transparent mirror was used separating equally into reference and probe. After the probe beam passed a translational stage (M-ILS250CCL, New-

port) both were focused 5 mm apart into the sample (2 mM, solvent: THF) in a stainless steel sample cell with an optical path of 0.8 mm enclosed by two CaF<sub>2</sub> windows (1 mm each, optically polished, Korth Kristalle) and stirred by a rotating magnet bar. A combination of polychromator (Chromex 250is, Bruker Optics) and liquid nitrogen cooled 2x32-element MCT-detector (IR-6416 system MCT-32/2-10, infrared systems development corporation) measured the spectra.

The pump (wavelength: 400 nm) was produced using the spare 40% laser output and a BBO (beta-barium borate) crystal. The beam was passing a perforated rotating plate, its polarization was rotated to 54.7°, it was attenuated to 0.5 μJ and focused into the cell superimposing with the probe beam.

The spectra were measured in regions without strong solvent absorption and corrected in baseline, slope and offset and merged together.

### 3.2.13 UVvis spectroscopy

UVvis spectra were recorded on an Agilent Cary 60 equipped with an Unisoku Cryostat (CoolSpek) and magnetic stirrer using quartz cuvettes with an attached tube and a screw cap with a septum or a J-Young-cap. All UVvis samples were prepared in a glovebox and transferred out of the glovebox prior to the measurement.

### 3.2.14 Vibrational spectroscopy

IR spectra were recorded using a Bruker ALPHA FT-IR spectrometer with Platinum ATR module.

All Resonance Raman spectra except for **3** were recorded using a Horiba Scientific LabRAM HR 800 spectrometer with open-electrode CCD detector in combination with a free space optical microscope and a He:Ne-laser (632.8 nm). The Resonance Raman spectra for **3** were recorded using a Triple Raman Spectrometer TR 557 from S& I (Spectroscopy & Imaging GmbH).

### 3.3 Synthesis<sup>n</sup>

#### 3.3.1 [WCl<sub>3</sub>(PNP)] (**5**)

Complexation of WCl<sub>4</sub>

WCl<sub>4</sub> (509 mg, 1.54 mmol, 1.1 equiv.) was added to a mixture of Et<sub>3</sub>N (0.4 mL, 288 mg, 2.85 mmol, 2.1 equiv.) and HN(CH<sub>2</sub>CH<sub>2</sub>P<sup>t</sup>Bu<sub>2</sub>)<sub>2</sub> (500 mg, 1.38 mmol, 1.0 equiv.) in benzene (50 mL) and stirred for minimum 5 d at 90 °C. After removal of the solvent *in vacuo*, the crude product was extracted with benzene (4x 15 mL) and dried *in vacuo*. The residue was dissolved in THF (4 mL), layered with pentane (20 mL) and stored at -40 °C to give **5** as dark yellow crystals (540 mg, 60%).

Oxidation of **10**

In a J-Young NMR-tube **10** (6.4 mg, 10.1 μmol, 1.0 equiv.) and NCS (3.0 mg, 22.1 μmol, 2.2 equiv.) were dissolved in C<sub>6</sub>D<sub>6</sub>. The mixture was irradiated with λ > 305 nm in a waterbath for three hours showing a color-change from deep purple to yellow-brownish. **5** was obtained in 30% spectroscopic yield.

<sup>1</sup>H NMR (C<sub>6</sub>D<sub>6</sub>, 300 MHz, [ppm]): δ = 9.13 (*s<sub>br</sub>*, CH<sub>2</sub>), 0.82 (*s<sub>br</sub>*, CMe<sub>3</sub>), -139.5 (*s<sub>br</sub>*, CH<sub>2</sub>).

**Elem. Anal.** found (calc) for C<sub>20</sub>H<sub>44</sub>Cl<sub>3</sub>NP<sub>2</sub>W: C 36.85 (36.92); H 6.93 (6.82); N 2.16 (2.15).

### 3.3 Synthesis

#### 3.3.2 $[(N_2)\{WCl(PNP)\}_2]$ (**1**)

Under an  $N_2$  atmosphere **5** (250 mg, 0.384 mmol, 1.0 equiv.) and NaHg (11.5 g, 0.845 mmol, 2.2 equiv.) were stirred in THF (10 mL) for 3 h at 0 °C to give a color change from yellow to dark green.

After extraction with THF (3x 8 mL) the solvent was removed *in vacuo*. The residue was then washed with pentane (3x 8 mL), extracted with benzene (5x 8 mL) and dried *in vacuo*. After column chromatography over Silica gel 60 silanized using benzene as eluent and lyophilisation out of benzene, **1** was obtained as a green powder (150 mg, 66%).

For  $^{15}N_2$  labeling the synthesis was done using an  $^{15}N_2$  atmosphere.

$^1H$  NMR (THF- $d_8$ , 500 MHz, [ppm]):  $\delta$  = 3.66 (m, 4 H, NCH<sub>2</sub>), 3.54 (m, 4 H, NCH<sub>2</sub>), 2.39 (m, 2 H, PCH<sub>2</sub>), 2.29 (m, 2 H, PCH<sub>2</sub>), 1.74 (m, 2 H, PCH<sub>2</sub>), 1.55 (d,  $^3J_{HP}$ =12.8 Hz, 18 H, 2x CMe<sub>3</sub>), 1.35 (m, 2 H, PCH<sub>2</sub>), 1.16 (d,  $^3J_{HP}$ =13.9 Hz, 18 H, 2x CMe<sub>3</sub>), 1.13 (d,  $^3J_{HP}$ =12.8 Hz, 36 H, 4x CMe<sub>3</sub>).

$^{13}C\{^1H\}$  NMR (THF- $d_8$ , 126 MHz, [ppm]):  $\delta$  = 30.7 (d,  $^2J_{CP}$  = 4.3 Hz, 2x CMe<sub>3</sub>), 30.7 (d,  $^2J_{CP}$  = 5.7 Hz, 2x CMe<sub>3</sub>), 30.8 (d,  $^2J_{CP}$  = 3.9 Hz, 2x CMe<sub>3</sub>), 31.8 (d,  $^1J_{CP}$  = 7.62 Hz, 2x PCH<sub>2</sub>), 31.6 (d,  $^1J_{CP}$  = 7.35 Hz, 2x PCH<sub>2</sub>), 32.0 (d,  $^2J_{CP}$  = 4.9 Hz, 2x CMe<sub>3</sub>), 38.5-38.9 (m, PCMe<sub>3</sub>), 78.9 (s, 2x NCH<sub>2</sub>), 79.4 (s, 2x NCH<sub>2</sub>).

$^{15}N\{^1H\}$  NMR (THF- $d_8$ , 50.7 MHz, [ppm]):  $\delta$  = 31.1 (s).

$^{31}P\{^1H\}$  NMR (THF- $d_8$ , 162 MHz, [ppm]):  $\delta$  = 92.9 (d,  $^2J_{PP}$  = 147.4 Hz), 87.8 (d,  $^2J_{PP}$  = 147.4 Hz).

### 3.3 Synthesis

#### 3.3.3 $[(N_2)\{WCl(PNP)\}_2]^+$ (**2**)

via oxidation

$Ag[BPh_4]$  (14.4 mg, 33.7  $\mu$ mol, 1.0 equiv.) was added to a solution of **1** (40.0 mg, 33.7  $\mu$ mol, 1.0 equiv.) in THF (5 mL) leading to a direct color change from green to dark brown. After stirring for 1 h the mixture was filtrated over celite, dried *in vacuo*, washed with pentane (3x 4 mL) and extracted with THF (2x 4 mL). After removal of the solvent *in vacuo* **2**- $[BPh_4]$  was obtained as a dark brown solid (43 mg, 85%).

via protonation

$[H(OEt_2)_2][BARF_{24}]$  (31 mg, 30.6  $\mu$ mol, 1.0 equiv.) was added to a solution of **1** (40.0 mg, 33.7  $\mu$ mol, 1.1 equiv.) in  $Et_2O$  (8 mL) leading to a direct color change from green to dark brown. After stirring for 1 h the mixture was filtrated, dried *in vacuo* and washed with pentane (3x 10 mL). The crude product was then extracted over celite with  $Et_2O$  and dried *in vacuo* to give **2** as a brown solid (47 mg, 75%).

$^1H$  NMR (THF- $d_8$ , 300 MHz, [ppm]):  $\delta$  = 4.37 ( $s_{br}$ , CHH), 3.13 ( $s_{br}$ ,  $CMe_3$ ), 2.99 ( $s_{br}$ ,  $CMe_3$ ), 2.51 ( $s_{br}$ ,  $CMe_3$ ), 2.38 ( $s_{br}$ ,  $CMe_3$ ), -5.60 ( $s_{br}$ , CHH), -14.1 ( $s_{br}$ , CHH), -22.1 ( $s_{br}$ , CHH), -25.1 ( $s_{br}$ , CHH), -27.8 ( $s_{br}$ , CHH).

**Elem. Anal.** found (calc) for  $C_{64}H_{108}BCl_2N_4P_4W_2$  (**2**- $[BPh_4]$ ): C 51.52 (51.01); H 7.17 (7.22); N 3.29 (3.72).

**rRaman** ( $\lambda_{ex}$  = 457 nm, frozen THF- $d_8$ ,  $cm^{-1}$ ):  $\tilde{\nu}$  = 1414 ( $^{14}N_2$ ); 1360 ( $^{15}N_2$ ).

**HR-ESI-MS** found (calc) for  $[C_{40}H_{88}Cl_2N_4P_4W_2]^+$ : 1186.4347 (1186.4339), 1188.4368 (1188.4380).

### 3.3 Synthesis

#### 3.3.4 $[(N_2)\{WCl(PNP)\}_2]^{2+}$ (**3**)

via oxidation

To a solution of **1** (20.0 mg, 16.8  $\mu\text{mol}$ , 1.0 equiv.) in Ph-Cl (8 mL)  $\text{Ag}[\text{Al}(\text{OC}(\text{CF}_3)_3)_4]$  (35.3 mg, 32.8  $\mu\text{mol}$ , 2.0 equiv.) was added. The solution was stirred under exclusion of light for 12 h. Afterwards the precipitate was filtered off, washed with benzene (6 ml) and extracted with DCM (16 mL). The solution was concentrated *in vacuo*, layered with pentane and stored at  $-40^\circ\text{C}$  for 3 d. The resulting brown precipitate was decanted, washed with pentane (2x 2 mL), extracted with THF and dried *in vacuo* to give **3** as a brown solid (39.3 mg, 75%).

via protonation

A solution of  $[\text{H}(\text{OEt}_2)_2][\text{Al}(\text{OC}(\text{CF}_3)_3)_4]$  (9.9 mg, 8.84  $\mu\text{mol}$ , 2.1 equiv.) in  $\text{Et}_2\text{O}$  (2 mL) was added dropwise to a suspension of **1** (5.0 mg, 4.21  $\mu\text{mol}$ , 1.0 equiv.) in  $\text{Et}_2\text{O}$  (5 mL). After stirring for 12 h all volatiles were removed *in vacuo* and the remaining yellowish brown residue was taken up in  $\text{THF}-d_8$  (90% spectroscopic yield).

**$^1\text{H NMR}$**  ( $\text{THF}-d_8$ , 400 MHz, [ppm]):  $\delta = 4.32$  (s<sub>br</sub>,  $\text{CMe}_3$ ), 4.19 (s<sub>br</sub>,  $\text{CMe}_3$ ), 3.78 (s<sub>br</sub>,  $\text{CMe}_3$ ), 3.49 (s<sub>br</sub>,  $\text{CMe}_3$ ), -1.56 (s<sub>br</sub>, CHH), -7.03 (s<sub>br</sub>, CHH), -8.81 (s<sub>br</sub>, CHH), -8.99 (s<sub>br</sub>, CHH), -32.1 (s<sub>br</sub>, CHH), -46.9 (s<sub>br</sub>, CHH), -56.6 (s<sub>br</sub>, CHH), -62.0 (s<sub>br</sub>, CHH).

**Elem. Anal.** found (calc) for  $\text{C}_{72}\text{H}_{88}\text{Al}_2\text{Cl}_2\text{F}_{72}\text{N}_4\text{O}_8\text{P}_4\text{W}_2$  (**3**- $[\text{Al}(\text{OC}(\text{CF}_3)_3)_4]$ ): C 29.2 (29.4); H 3.30 (3.01); N 1.66 (1.90).

**rRaman** ( $\lambda_{\text{ex}} = 633 \text{ nm}$ ,  $-100^\circ\text{C}$ ,  $\text{THF}-d_8$ ,  $\text{cm}^{-1}$ ):  $\tilde{\nu} = 1400$  ( $^{14}\text{N}_2$ ); 1356 ( $^{15}\text{N}_2$ ).

**HR-ESI-MS** found (calc) for  $[\text{C}_{40}\text{H}_{88}\text{Cl}_2\text{N}_4\text{P}_4\text{W}_2]^{2+}$ : 593.2181 (593.2166), 594.2182 (594.2177).

### 3.3 Synthesis

#### 3.3.5 $[\text{W}(\text{N})\text{Cl}(\text{P}^{\text{H}}\text{PNP})]^+$ (**11**)

At  $-78\text{ }^{\circ}\text{C}$  to a solution of **1** (50 mg, 42.1  $\mu\text{mol}$ , 1.0 equiv.) in THF (8 mL) was added a solution of HOTf (7.8  $\mu\text{L}$ , 13.3 mg, 88.4 mmol, 2.1 equiv.) in THF (6 mL) leading to a color change from green to brownish orange. After stirring for 3 h the solution was warmed to r.t. and dried *in vacuo*. The residue was then washed with pentane (4x 5 mL), extracted with benzene (3x 4 mL) and concentrated *in vacuo*. Diffusion of pentane into a saturated benzene solution at r.t. gives **26**-OTf as pale yellow crystals (48 mg, 60%).

**Elem. Anal.** found (calc) for  $\text{C}_{21}\text{H}_{45}\text{ClF}_3\text{N}_2\text{O}_3\text{P}_2\text{SW} \cdot 0.8\text{C}_6\text{H}_6$ : C 38.23 (38.34); H 6.21 (6.22); N 3.29 (3.46).

### 3.3 Synthesis

#### 3.3.13 [WCl(CO)<sub>2</sub>(PNP)] (10)

Oxidation of **9**

At -40 °C a solution of N-chlorosuccinimide (25.5 mg, 0.19 mmol, 1.2 equiv.) in THF (7 mL) was added to a solution of **9** (100 mg, 0.16 mmol, 1.0 equiv.) in THF (6 mL). The reaction was stirred for 4 h while warming to r.t. and dried *in vacuo*. The resulting brownish-violet residue was extracted with Et<sub>2</sub>O (5x 5 mL) at -40 °C. The filtrate was dried *in vacuo*, side products were removed *via* sublimation under vacuum at 85 °C and **10** was obtained as a dark violet powder (56 mg, 55%).

Salt metathesis of **21**

To a solution of **21** (5.0 mg, 7.8 μmol, 1.0 equiv.) in THF-d<sub>8</sub> (0.5 ml) was added TMS-Cl (1.0 μL, 0.9 mg, 7.8 μmol, 1.0 equiv.). The solution was stirred over night to give **10** and TMS-NCO (both >99% spectroscopic yield). The formed TMS-NCO could be separated *via* vacuum trap-to-trap transfer.

<sup>1</sup>H{<sup>31</sup>P} NMR (C<sub>6</sub>D<sub>6</sub>, 300 MHz, [ppm]): δ = 3.13-2.99 (m, 2 H, 2x NCHH), 2.70-2.58 (m, 2 H, 2x NCHH), 2.05-1.84 (m, 4 H, 4x PCHH), 1.34 (s, 18 H, 2x CMe<sub>3</sub>), 1.10 (s, 18 H, 2x CMe<sub>3</sub>).

<sup>13</sup>C{<sup>1</sup>H} NMR (C<sub>6</sub>D<sub>6</sub>, 126 MHz, [ppm]): δ = 26.9 (AXY, N = |<sup>1</sup>J<sub>AX</sub> + <sup>3</sup>J<sub>AY</sub>| = 17.1 Hz, 2x PCH<sub>2</sub>), 30.1 (AXY, N = |<sup>2</sup>J<sub>AX</sub> + <sup>4</sup>J<sub>AY</sub>| = 4.6 Hz, 2x CMe<sub>3</sub>), 31.0 (AXY, N = |<sup>2</sup>J<sub>AX</sub> + <sup>4</sup>J<sub>AY</sub>| = 4.0 Hz, 2x CMe<sub>3</sub>), 37.8 (AXY, N = |<sup>1</sup>J<sub>AX</sub> + <sup>3</sup>J<sub>AY</sub>| = 13.6 Hz, 2x PCMe<sub>3</sub>), 38.5 (AXY, N = |<sup>1</sup>J<sub>AX</sub> + <sup>3</sup>J<sub>AY</sub>| = 14.6 Hz, 2x PCMe<sub>3</sub>), 67.9 (AXY, N = |<sup>2</sup>J<sub>AX</sub> + <sup>4</sup>J<sub>AY</sub>| = 11.0 Hz, 2x NCH<sub>2</sub>), 259 (t, <sup>2</sup>J = 8.7 Hz, CO), 264 (t, <sup>2</sup>J = 4.8 Hz, CO).

<sup>31</sup>P{<sup>1</sup>H} NMR (C<sub>6</sub>D<sub>6</sub>, 162 MHz, [ppm]): δ = 73.9 (s).

**Elem. Anal.** found (calc) for C<sub>22</sub>H<sub>44</sub>ClNO<sub>2</sub>P<sub>2</sub>W: C 41.35 (41.56); H 7.00 (6.98); N 2.19 (2.20).

### 3.3 Synthesis

#### Characterization of TMS-NCO

$^1\text{H}$  NMR (THF- $d_8$ , 300 MHz, [ppm]):  $\delta = 0.25$  (s, 9 H, Si( $\text{Me}_3$ )).

$^{13}\text{C}\{^1\text{H}\}$  NMR (THF- $d_8$ , 126 MHz, [ppm]):  $\delta = 0.78$  (s, Si( $\text{Me}_3$ )).

$^{29}\text{Si}\{^1\text{H}\}$  NMR (THF- $d_8$ , 90.4 MHz, [ppm]):  $\delta = 4.5$  (s, Si( $\text{Me}_3$ )).

#### Characterization of TMS- $^{15}\text{NCO}$

$^1\text{H}$  (THF- $d_8$ , 500 MHz, [ppm]):  $\delta = 0.25$  (d,  $^3J_{\text{HN}} = 1.4$  Hz, 9 H, Si( $\text{Me}_3$ )).

$^{13}\text{C}\{^1\text{H}\}$  NMR (THF- $d_8$ , 126 MHz, [ppm]):  $\delta = 0.79$  (d,  $^2J_{\text{CN}} = 2.8$  Hz, Si( $\text{Me}_3$ )).

$^{15}\text{N}\{^1\text{H}\}$  NMR (THF- $d_8$ , 50.7 MHz, [ppm]):  $\delta = -346$  (s).

$^{29}\text{Si}\{^1\text{H}\}$  NMR (THF- $d_8$ , 90.4 MHz, [ppm]):  $\delta = 4.5$  (d,  $^1J_{\text{SiN}} = 14.2$  Hz).

#### 3.3.14 $[\text{W}(\text{N}_3)(\text{CO})_2(\text{PNP})]$ (**19**)

**18** (20 mg, 27.5  $\mu\text{mol}$ , 1.0 equiv.) and  $[\text{nBu}_4\text{N}]\text{N}_3$  (9.4 mg, 33  $\mu\text{mol}$ , 1.2 equiv.) were stirred in THF for 30 min. After removal of the solvent *in vacuo* the product was extracted with  $\text{Et}_2\text{O}$  over celite. After drying *in vacuo* **19** was obtained as red-purple solid (17 mg, 96%).

$^1\text{H}\{^{31}\text{P}\}$  NMR ( $\text{C}_6\text{D}_6$ , 300 MHz, [ppm]):  $\delta = 3.01$  (m, 2 H, 2x NCHH), 2.61 (m, 2 H, 2x NCHH), 1.81 (m, 4 H, 4x PCHH), 1.20 (s, 18 H, 2x  $\text{CMe}_3$ ), 1.03 (s, 18 H, 2x  $\text{CMe}_3$ ).

$^{13}\text{C}\{^1\text{H}\}$  NMR ( $\text{C}_6\text{D}_6$ , 126 MHz, [ppm]):  $\delta = 26.6$  (AXY,  $\text{N} = |^1J_{\text{AX}} + ^3J_{\text{AY}}| = 17.1$  Hz, 2x  $\text{PCH}_2$ ), 29.8 (m, 2x  $\text{CMe}_3$ ), 30.2 (m, 2x  $\text{CMe}_3$ ), 36.9 (AXY,  $\text{N} = |^1J_{\text{AX}} + ^3J_{\text{AY}}| = 14.3$  Hz, 2x  $\text{PCMe}_3$ ), 37.2 (AXY,  $\text{N} = |^1J_{\text{AX}} + ^3J_{\text{AY}}| = 14.2$  Hz, 2x  $\text{PCMe}_3$ ), 67.6 (m, 2x NCH $_2$ ), 262 (t,  $^2J = 8.5$  Hz, CO), 264 (t,  $^2J = 4.4$  Hz, CO).

$^{31}\text{P}\{^1\text{H}\}$  NMR ( $\text{C}_6\text{D}_6$ , 162 MHz, [ppm]):  $\delta = 77.7$  (s).

IR (ATR-IR,  $\text{cm}^{-1}$ ):  $\tilde{\nu} = 2072$  (N=N=N), 1907 ( $\text{C}\equiv\text{O}$ ), 1828 ( $\text{C}\equiv\text{O}$ ).

### 3.3 Synthesis

#### 3.3.15 $[\text{W}(\text{N})(\text{CO})(\text{H}^{\text{P}}\text{PNP})]^+$ (**20**)

salt metathesis route

**18** (110 mg, 0.151 mmol, 1.1 equiv.) and  $[\text{nBu}_4\text{N}]\text{N}_3$  (51 mg, 0.179 mmol, 1.3 equiv.) were dissolved in THF (6 mL) and stirred for 30 min at r.t. After evaporation of the solvent, the residue was extracted with  $\text{Et}_2\text{O}$  at  $-30\text{ }^\circ\text{C}$  into a solution of  $[\text{LutH}][\text{OTf}]$  (35.4 mg, 0.138 mmol, 1.0 equiv.) in THF (2 mL). The mixture was stirred for 2 h, warmed to r.t. and dried *in vacuo*. The residue was then washed with pentane (5x 4 mL) and  $\text{Et}_2\text{O}$  (2x 2 mL) and extracted with benzene. After evaporation of the solvent **20** was obtained as deep blue powder (55 mg, 55%)

protonation of **16**

**16** (7.2 mg, 12.3  $\mu\text{mol}$ , 1.2 equiv.) and  $[\text{LutH}][\text{BARF}_{24}]$  were stirred in  $\text{Et}_2\text{O}$  (4 mL). After evaporation of the solvent, the residue was washed with pentane (2x 2 mL) and extracted with  $\text{Et}_2\text{O}$ . After evaporation of the solvent *in vacuo* **20** was obtained as dark powder (14.7 mg, 89%).

$^1\text{H}\{^{31}\text{P}\}$  NMR ( $\text{C}_6\text{D}_6$ , 500 MHz, [ppm]):  $\delta = 5.92$  (m, 1 H, N-H), 4.03-4.00 (m, 2 H, 2x NCHH) 2.58-2.50 (m, 2 H, 2x NCHH), 2.31-2.24 (m, 2 H, 2x PCHH), 1.62-1.58 (m, 2 H, 2x PCHH), 1.15 (s, 18 H, 2x  $\text{CMe}_3$ ), 0.77 (s, 18 H, 2x  $\text{CMe}_3$ ).

$^{13}\text{C}\{^1\text{H}\}$  NMR ( $\text{C}_6\text{D}_6$ , 126 MHz, [ppm]):  $\delta = 22.9$  (AXY,  $\text{N} = |^1\text{J}_{\text{AX}} + ^3\text{J}_{\text{AY}}| = 9.1$  Hz, 2x PCH<sub>2</sub>), 28.0 (AXY,  $\text{N} = |^2\text{J}_{\text{AX}} + ^4\text{J}_{\text{AY}}| = 2.0$  Hz, 2x  $\text{CMe}_3$ ), 28.4 (AXY,  $\text{N} = |^2\text{J}_{\text{AX}} + ^4\text{J}_{\text{AY}}| = 2.7$  Hz, 2x  $\text{CMe}_3$ ), 34.5 (AXY,  $\text{N} = |^1\text{J}_{\text{AX}} + ^3\text{J}_{\text{AY}}| = 8.8$  Hz, 2x PCMe<sub>3</sub>), 35.4 (AXY,  $\text{N} = |^1\text{J}_{\text{AX}} + ^3\text{J}_{\text{AY}}| = 10.9$  Hz, 2x PCMe<sub>3</sub>), 58.4 (AXY,  $\text{N} = |^2\text{J}_{\text{AX}} + ^4\text{J}_{\text{AY}}| = 3.8$  Hz, 2x NCH<sub>2</sub>), 279 (m, CO).

$^{15}\text{N}\{^1\text{H}\}$  NMR ( $\text{C}_6\text{D}_6$ , 50.7 MHz, [ppm]):  $\delta = 445.7$  (s).

$^{31}\text{P}\{^1\text{H}\}$  NMR ( $\text{C}_6\text{D}_6$ , 203 MHz, [ppm]):  $\delta = 93.1$  (s).

**Elem. Anal.** found (calc) for  $\text{C}_{53}\text{H}_{57}\text{BF}_{24}\text{N}_2\text{OP}_2\text{W}$  (**20**- $[\text{BARF}_{24}]$ ): C 44.21 (43.88); H 4.00 (3.96); N 1.72 (1.94).

### 3.3 Synthesis

#### 3.3.16 [W(NCO)(CO)<sub>2</sub>(PNP)] (**21**)

Carbonylation of [W(N)(CO)(PNP)] (**16**)

In a J-Young NMR tube **16** (6.0 mg, 10  $\mu$ mol) was dissolved in C<sub>6</sub>D<sub>6</sub>. The NMR tube was degassed *via* two freeze-pump-thaw cycles and set under CO (1 atm). After stirring for 16 h the solution was degassed again *via* two freeze-pump-thaw cycles to give **21** (85% spectroscopic yield).

Salt-metathesis of [W(CO)<sub>2</sub>(PNP)] (**18**)

**18** (26.0 mg, 35.7  $\mu$ mol, 1.0 equiv.) and [nBu<sub>4</sub>N][NCO] (12.2 mg, 42.9  $\mu$ mol, 1.2 equiv.) were stirred in THF (5 mL) for 1 h at r.t. Afterwards the solvent was removed *in vacuo* and the purple residue extracted with Et<sub>2</sub>O over Celite. After removal of the solvent *in vacuo*, column chromatography over silanized silica 60 using benzene as eluent and lyophilization **21** was obtained as a purple powder (18.5 mg, 80%).

<sup>1</sup>H{<sup>31</sup>P} NMR (C<sub>6</sub>D<sub>6</sub>, 500 MHz, [ppm]):  $\delta$  = 3.01-2.95 (m, 2 H, 2x NCHH), 2.56-2.50 (m, 2 H, 2x NCHH), 1.88-1.76 (m, 4 H, 2x PCHH), 1.21 (s, 18 H, 2x CMe<sub>3</sub>), 1.02 (s, 18 H, 2x CMe<sub>3</sub>).

3.3.19 [WCl(CN<sup>t</sup>Bu)<sub>2</sub>(PNP)] (6)

A mixture of **5** (100 mg, 0.154 mmol, 1.0 equiv.), NaHg (4.60 g, 0.338 mmol, 2.2 equiv.) and CN-<sup>t</sup>Bu (38.2  $\mu$ L, 28.1 mg, 0.338 mmol, 2.2 equiv.) was stirred for 4 h at r.t. in THF. After evaporation of the solvent, extraction over silanized Silica 60 with pentane as eluent and lyophilisation out of benzene **6** was obtained as a green solid (35 mg, 30%).

**<sup>1</sup>H{<sup>31</sup>P} NMR** (C<sub>6</sub>D<sub>6</sub>, 500 MHz, [ppm]):  $\delta$  = 3.25-3.20 (m, 2 H, NCHH), 2.90-2.84 (m, 2 H, NCHH), 2.12-2.07 (m, 2 H, PCHH), 1.99-1.92 (m, 2 H, PCHH), 1.52 (s, 18 H, 2x P(CMe<sub>3</sub>)<sub>2</sub>), 1.47 (s, 9 H, CN-CMe<sub>3</sub>), 1.34 (s, 18 H, 2x P(CMe<sub>3</sub>)<sub>2</sub>), 1.14 (s, 9 H, CN-CMe<sub>3</sub>).

**<sup>13</sup>C{<sup>1</sup>H} NMR** (C<sub>6</sub>D<sub>6</sub>, 126 MHz, [ppm]):  $\delta$  = 28.3 (AXY, N =  $|^1J_{AX} + ^3J_{AY}|$  = 13.8 Hz, 2x PCH<sub>2</sub>), 31.5 (AXY, N =  $|^2J_{AX} + ^4J_{AY}|$  = 5.2 Hz, 2x P(CMe<sub>3</sub>)<sub>2</sub>), 31.7 (AXY, N =  $|^2J_{AX} + ^4J_{AY}|$  = 4.1 Hz, 2x P(CMe<sub>3</sub>)<sub>2</sub>), 32.2 (s, CN-CMe<sub>3</sub>), 32.6 (s, CN-CMe<sub>3</sub>), 38.0 (AXY, N =  $|^1J_{AX} + ^3J_{AY}|$  = 11.5 Hz, 2x P(CMe<sub>3</sub>)<sub>2</sub>), 40.1 (AXY, N =  $|^1J_{AX} + ^3J_{AY}|$  = 12.7 Hz, 2x P(CMe<sub>3</sub>)<sub>2</sub>), 58.5 (s, CN-CMe<sub>3</sub>), 63.5 (s, CN-CMe<sub>3</sub>), 69.8 (AXY, N =  $|^2J_{AX} + ^4J_{AY}|$  = 11.7 Hz, 2x NCH<sub>2</sub>), 213 (s, CN-<sup>t</sup>Bu), 247 (s, CN-<sup>t</sup>Bu).

**<sup>31</sup>P{<sup>1</sup>H} NMR** (C<sub>6</sub>D<sub>6</sub>, 162 MHz, [ppm]):  $\delta$  = 73.7 (s).

**Elem. Anal.** found (calc) for C<sub>30</sub>H<sub>62</sub>ClN<sub>3</sub>P<sub>2</sub>W: C 48.27 (48.30), H 8.35 (8.38), N 5.63 (5.59).

**IR** (ATR-IR, cm<sup>-1</sup>):  $\tilde{\nu}$  = 1964 (C $\equiv$ N), 1842 (C $\equiv$ N).

3.3.20 Na[W(CO)<sub>2</sub>(PNP)] (24)Deprotonation of **9**

**9** (100 mg, 0.159 mmol, 1.0 equiv.) and NaHMDS (32 mg, 0.175 mmol, 1.1 equiv.) were stirred in THF showing a color change from yellow to bright orange. After 30 min the solvent was removed *in vacuo* and the residue was washed with pentane (3x 8 mL). After extraction with THF **24** was obtained as a bright orange solid (59 mg, 60%).

Reduction of **18**

**18** (20 mg, 27.5  $\mu\text{mol}$ , 1.0 equiv.) and NaHg (823 mg, 60.5  $\mu\text{mol}$ , 2.2 equiv.) were stirred in THF for 4 h while the color changes from purple to orange. The mixture was dried *in vacuo* and extracted with THF. After evaporation of the solvent **24** was obtained as orange solid (15 mg, 87%).

Addition of 15-cr-5 (1.0 equiv.) makes the compound soluble in benzene. In this way crystals suitable for X-ray diffraction could be obtained by diffusion of pentane into a saturated THF solution of  $-40\text{ }^\circ\text{C}$ .

**<sup>1</sup>H{<sup>31</sup>P} NMR** (THF-*d*<sub>8</sub>, 500 MHz, [ppm]):  $\delta$  = 3.22 (t, <sup>2</sup>J<sub>HH</sub> = 6.42 Hz, 4 H, NCH<sub>2</sub>), 1.94 (t, <sup>2</sup>J<sub>HH</sub> = 6.39 Hz, 4 H, PCH<sub>2</sub>), 1.32 (s, 36 H, 4x P(CMe<sub>3</sub>)<sub>2</sub>).

**<sup>13</sup>C{<sup>1</sup>H} NMR** (THF-*d*<sub>8</sub>, 126 MHz, [ppm]):  $\delta$  = 27.4 (AXY, N = |<sup>1</sup>J<sub>AX</sub> + <sup>3</sup>J<sub>AY</sub>| = 10.8 Hz, 2x PCH<sub>2</sub>), 30.9 (AXY, N = |<sup>2</sup>J<sub>AX</sub> + <sup>4</sup>J<sub>AY</sub>| = 6.3 Hz, 4x P(CMe<sub>3</sub>)<sub>2</sub>), 38.5 (AXY, N = |<sup>1</sup>J<sub>AX</sub> + <sup>3</sup>J<sub>AY</sub>| = 11.5 Hz, 4x P(CMe<sub>3</sub>)<sub>2</sub>), 66.4 (AXY, N = |<sup>2</sup>J<sub>AX</sub> + <sup>4</sup>J<sub>AY</sub>| = 19.7 Hz, 2x NCH<sub>2</sub>), 240 (t, <sup>2</sup>J = 3.6 Hz, 2x CO).

**<sup>31</sup>P{<sup>1</sup>H} NMR** (THF-*d*<sub>8</sub>, 162 MHz, [ppm]):  $\delta$  = 105.4 (s).

**Elem. Anal.** found (calc) for C<sub>22</sub>H<sub>44</sub>NNaO<sub>2</sub>P<sub>2</sub>W: C 42.35 (42.39), H 6.97 (7.11), N 2.21 (2.25).

**IR** (ATR-IR, cm<sup>-1</sup>):  $\tilde{\nu}$  = 1677 (C≡O), 1604 (C=O).

### 3.4 Kinetic Analysis: Protonation of **1** with $[\text{HNEt}_3][\text{BAR}_{24}^{\text{F}}]$

#### 3.4.1 Exemplary UVvis spectrum

Figure 44: Exemplary UVvis spectrum of the protonation of **1** with  $[\text{HNEt}_3][\text{BAR}_{24}^{\text{F}}]$ . The blue trace represents the spectrum of pure **1**, the orange one the spectrum directly after addition of acid and the red one after 5 h reaction time.

#### 3.4.2 Determination of equilibrium constant $K_1$

A solution of  $[\text{HNEt}_3][\text{BAR}_{24}^{\text{F}}]$  in THF (0.25 mol·L<sup>-1</sup>; 20, 30, 40, 50 μL, respectively) was added to a stirred solution of **1** in THF (2 mL, 0.25 mmol·L<sup>-1</sup>) at 25 °C. The reaction was monitored by UVvis spectroscopy, measuring one spectrum every 3 sec.

Figure 45: Plot of the absorbance at 400 nm vs. the concentration of  $[\text{HNEt}_3][\text{BAR}_{24}^{\text{F}}]$  giving rise to the equilibrium constant  $K_1 = 1592 \pm 578 \text{ mol} \cdot \text{L}^{-1}$ .

### 3.4.3 Determination of rate constants $k_2$ and $k_3$

A solution of [HNEt<sub>3</sub>][BAR<sub>24</sub><sup>F</sup>] (0.5, 5, 7.5, 10, 12.5 mmol·L<sup>-1</sup>) in THF (1 mL) was added to a solution of **1** (0.5 mmol·L<sup>-1</sup>) in THF (1 mL) at 25 °C. The reaction was stirred and monitored *via* UVvis spectroscopy for 5 h, measuring one spectrum every 4 min.

### 3.4.4 Determination of rate constant $k_3$ via initial rate method

The rate constant  $k_3$  was determined *via* the initial rate method using an equimolar mixture of **1** and [HNEt<sub>3</sub>][BAR<sub>24</sub><sup>F</sup>] (both 0.25 mmol·L<sup>-1</sup>). It is assumed that under such conditions the reaction proceeds mainly *via* Path B (Scheme 59). The initial rate was determined from the spectral changes ascribed to the decrease in the concentration of **12** after the time needed for setting of the first equilibrium and calculated to be  $v = 1.35 \cdot 10^{-9}$  mol·L<sup>-1</sup>·s<sup>-1</sup>. Taking the previously determined equilibrium constant  $K_1$  into account, the concentration of **12** in the equilibrium was calculated to be  $5.84 \cdot 10^{-5}$  mol·L<sup>-1</sup> (with  $K_1 = 1592$  mol·L<sup>-1</sup> and  $c(\mathbf{1}) = 0.25$  mmol·L<sup>-1</sup>). With  $v = k_3 \cdot (c(\mathbf{12}))^2$ ,  $k_3$  was calculated as  $k_3 = 0.4$  L·mol<sup>-1</sup>·s<sup>-1</sup>.

Figure 46: Absorbance at 607 nm vs time plot for different ratios of [HNEt<sub>3</sub>][BAR<sub>24</sub><sup>F</sup>] to **1**.

### 3.5 Kinetic Analysis: N<sub>2</sub>-cleavage of [(N<sub>2</sub>)<sub>2</sub>{W(CO)(PNP)}<sub>2</sub>](**4**)

#### 3.5.1 Reaction Monitoring

A J-Young NMR tube containing 0.5 mL of a 3.75 mM stock solution of **4** in Tol-d<sub>8</sub> was put into a pre-heated NMR machine. The decay of **4** was monitored *via* <sup>1</sup>H NMR at different temperatures. Each temperature was repeated at least twice.

Figure 47:  $c(\mathbf{4})$  vs. time plot at different temperatures. The triangles represent the measured concentrations, while the black lines represent the fitting curve.

## 3.5.2 Kinetic Modelling

The derived curves were fitted using the COPASI 4.27 (Build 213) software<sup>233</sup> according to the model shown in Scheme 80. The derived rate constants  $k_1$  and  $k_2$  as well as the so obtained equilibrium constants  $K$  and free energies  $\Delta G$  are given in Table 8.

Scheme 80: The equilibrium of **4** and **16** and the resulting rate law for the decay of **4** used to fit the kinetic curves.

Table 8: The derived rate constants  $k_1$  and  $k_2$  and the so obtained equilibrium constants  $K$  and  $\Delta G$ -values.

T [K]	$k_1$ [s <sup>-1</sup> ]	$k_2$ [L mol <sup>-1</sup> s <sup>-1</sup> ]	$K$ [mol L <sup>-1</sup> ]
348	$3.0 \cdot 10^{-5}$	$7.70 \cdot 10^{-4}$	0.039
	$3.2 \cdot 10^{-5}$	$8.63 \cdot 10^{-4}$	0.037
358	$1.0 \cdot 10^{-4}$	$16.4 \cdot 10^{-4}$	0.061
	$0.9 \cdot 10^{-4}$	$14.5 \cdot 10^{-4}$	0.062
368	$3.9 \cdot 10^{-4}$	$35.5 \cdot 10^{-4}$	0.110
	$3.8 \cdot 10^{-4}$	$36.9 \cdot 10^{-4}$	0.103
378	$9.8 \cdot 10^{-4}$	$82.0 \cdot 10^{-4}$	0.120
	$10.0 \cdot 10^{-4}$	$76.0 \cdot 10^{-4}$	0.132

### 3.5.3 Eyring Analysis

Figure 48: ln(k<sub>1</sub>/T) vs. 1/T plot (Eyring-plot) for the thermal splitting of **4** into **16**.

### 3.5.4 Van't Hoff Analysis

Figure 49: ln(K/T) vs. 1/T plot (Van't Hoff-plot) for the thermal splitting of **4** into **16**.

### 3.6 Transient spectroscopy

Figure 50: *left*: Transient UVVis difference spectra of **4** in THF at selected pump-probe delays (pump wavelength: 530 nm). The black line shows the scaled linear absorption spectrum. *right*: Time-dependence of the integrated absolute absorption changes (red line is a bi-exponential fit with  $\tau_1 = 1.8$  ps and  $\tau_2 = 11.1$  ps).

Figure 51: *left*: Transient UVVis difference spectra of **4** in THF at selected pump-probe delays (pump wavelength: 475 nm). The black line shows the scaled linear absorption spectrum. *right*: Time-dependence of the integrated absolute absorption changes (red line is a bi-exponential fit with  $\tau_1 = 1.5$  ps and  $\tau_2 = 9.2$  ps).

### 3.6 Transient spectroscopy

Figure 52: *left*: Transient UVvis difference spectra of **4** in THF at selected pump-probe delays (pump wavelength: 380 nm). The black line shows the scaled linear absorption spectrum. *right*: Time-dependence of the integrated absolute absorption changes (red line is a bi-exponential fit with  $\tau_1 = 1.1$  ps and  $\tau_2 = 8.3$  ps).

Figure 53: *left*: Transient UVvis difference spectra of **4** in THF at selected pump-probe delays (pump wavelength: 330 nm). The black line shows the scaled linear absorption spectrum. *right*: Time-dependence of the integrated absolute absorption changes (red line is a bi-exponential fit with  $\tau_1 = 1.3$  ps and  $\tau_2 = 9.9$  ps).

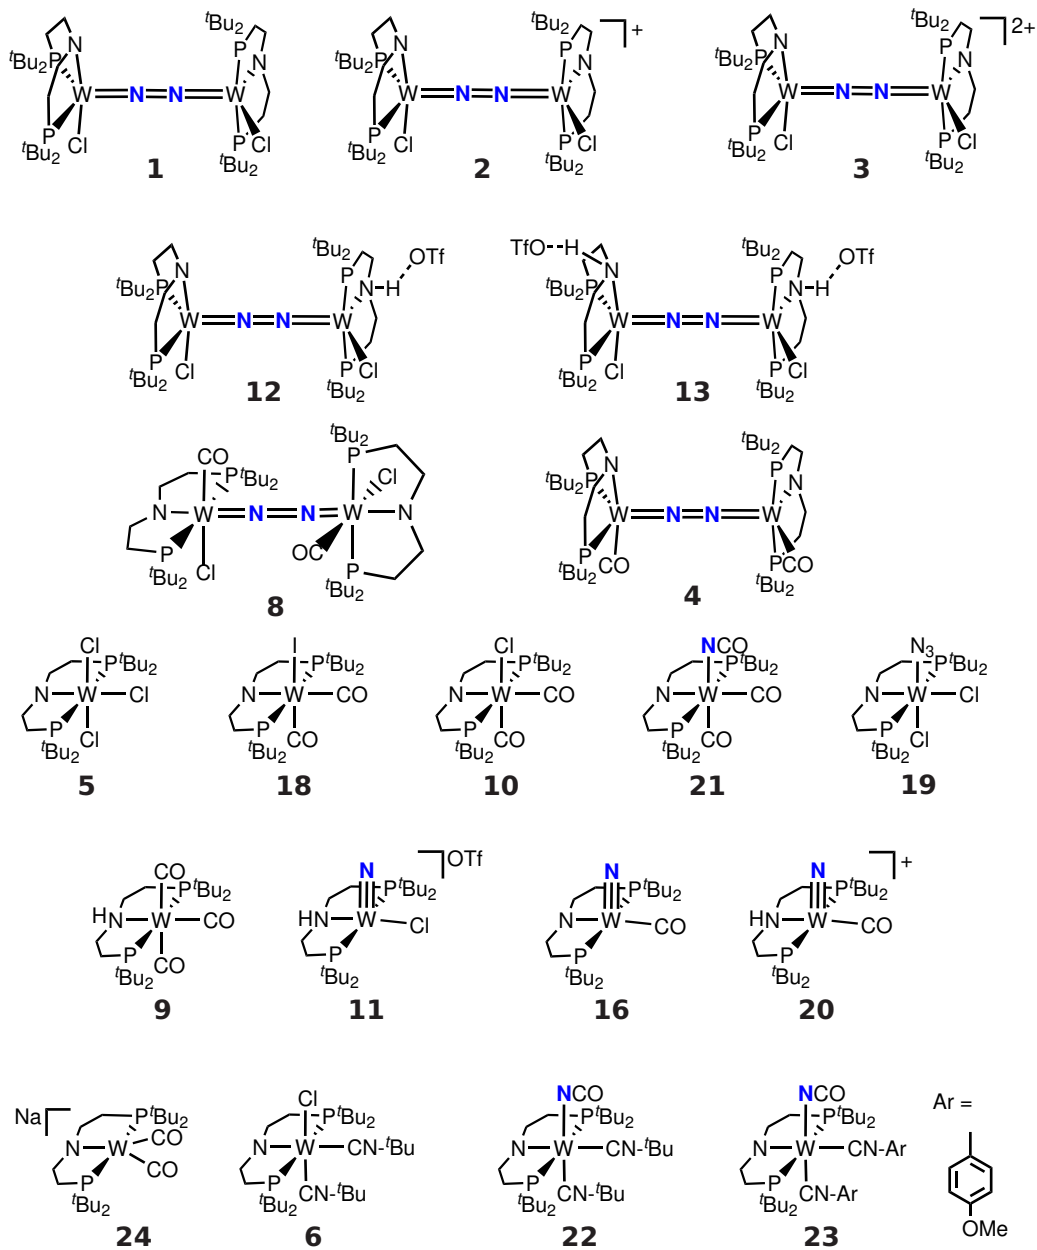

Figure 54: Transient IR difference spectra of **4** in THF at selected pump-probe delays (pump wavelength: 400 nm).

## 7 Curriculum Vitae

### Personal

Name Bastian Schluschaß  
Nationality German  
Date of Birth 19.10.1989  
Place of Birth Frankfurt am Main  
E-mail bschluss@gwdg.de

---

### Education

since May 2016 **Graduate Student**, *Georg-August-University, Göttingen (Germany)*  
Institute for Inorganic Chemistry,  
Research-group of Prof. Dr. Sven Schneider

2013-2016 **Master of Science**, *Georg-August-University, Göttingen (Germany)*  
Final Grade: 1.6  
Thesis title: "Reactivity of Co(PNP)-Pincer-Complexes" (Grade 1.0)  
Institute for Inorganic Chemistry,  
Research-group of Prof. Dr. Sven Schneider

2010-2013 **Bachelor of Science**, *Georg-August-University, Göttingen (Germany)*  
Final Grade: 1.6  
Thesis title: "Reactivity of Ru(PNP)-Nitrido-Pincer-Complexes" (Grade 1.7)  
Institute for Inorganic Chemistry,  
Research-group of Prof. Dr. Sven Schneider

---

### Experience

#### Traineeships

Jul - Oct 2017 **Internship**, *Indiana University, Indiana (USA)*  
Department of Chemistry, Research-group of Prof. Dr. Kenneth Caulton

Mar - Jun 2015 **Erasmus Internship**, *Stockholm University, Stockholm (Schweden)*  
Department of Organic Chemistry, Research-group of Dr. Eric V. Johnson

#### Contributions at Conferences

2019 15. Koordinationschemie-Treffen, Munich (Germany), *Talk*

2018 28th ICOMC, Florence (Italy), *Talk*

2018 14. Koordinationschemie-Treffen, Heidelberg (Germany), *Poster*

2017 9. Göttinger Chemie Forum, Göttingen (Germany), *Talk*

2017 5th COST Carisma Meeting, Lisbon (Portugal), *Talk*

2016 12. Koordinationschemie-Treffen, Kiel (Germany), *Poster*

---

## Publications

- "Selectivity of tungsten mediated dinitrogen splitting vs. proton reduction", Bastian Schluschaß, Josh Abbenseth, Serhiy Demeshko, Markus Finger, Alicija Franke, Christian Herwig, Christian Würtele, Ivana Ivanovic-Burmazovic, Christian Limberg, Joshua Telser and Sven Schneider, *Chemical Science*, **2019**, *10*, 10275-10282.
- "Dinitrogen Splitting Coupled to Protonation", Gleb A. Silantyeu, Moritz Förster, Bastian Schluschaß, Josh Abbenseth, Christian Würtele, Christian Volkmann, Max C. Holthausen and Sven Schneider, *Angewandte Chemie International Edition*, **2017**, *57*, 5872-5876.
- "Water oxidation mediated by ruthenium oxide nanoparticles supported on siliceous mesocellular foam" Karl P. J. Gustafson, Andrey Shatskiy, Oscar Verho, Markus D. Kärkäs, Bastian Schluschaß, Cheuk-Wai Tai, Björn Åkermark, Jan-Erling Bäckvall and Eric V. Johnston, *Catalysis, Science and Technology*, **2017**, *7*, 293-299.
- "Square-Planar Cobalt(III) Pincer Complex", Paraskevi O. Lagaditis, Bastian Schluschaß, Serhiy Demeshko, Christian Würtele and Sven Schneider, *Inorganic Chemistry*, **2016**, *55*, 4529-4536.
- "Electron-rich, Nitrido-bridged Ruthenium Complexes", Arne Glüer, Bjorn Askevold, Bastian Schluschaß, Frank W. Heinemann and Sven Schneider, *Zeitschrift für anorganische und allgemeine Chemie*, **2015**, *641*, 49-51.
