Tag der mündlichen Prüfung:

## Zusammenfassung

Die Bildung des Tat-Protein/TAR RNA-Komplexes ist ein entscheidender Schritt in der Regulation der Expression des HI-Virus (Human Immunodeficiency Virus, HIV). Für eine vollständige Transkription des viralen Gens ist die Interaktion des Tat/TARKomplexes mit dem positiven Transkriptionsfaktor-Komplex P-EFTb (Positive Transcription Elongation Factor) über dessen Cyclin T1-Komponente (CycT1) notwendig. Durch Mutagenesestudien wurde die Hexanukleotid-Schleife der TAR RNA als Kontaktstelle für die Wechselwirkung mit CycT1 identifiziert.
Zur Entwicklung neuer Arzneimittel gegen das HIV stellt die Störung des Zusammenspiels zwischen dem Tat/CycT1-Komplex und der TAR RNA ein lohnendes Ziel dar. Positiv geladene Verbindungen wie Aminoglycoside oder Peptidmimetika binden an die TAR RNA und brechen so den Tat/TAR-Komplex auf.

In dieser Arbeit wird die Bestimmung der dreidimensionalen Struktur des Komplexes zwischen der HIV-2 TAR RNA und einem Neooligoaminodeoxysaccharid mit Hilfe der NMR-Spektroskopie beschrieben. Im Gegensatz zu anderen Aminoglycosiden wechselwirkt diese neuartige Verbindung gleichzeitig mit den für die Bindung des Tat-Proteins verantwortlichen Resten des Bulges wie auch mit dem Adenosin 35 der Hexanukleotid-Schleife der TAR RNA. Diese Schleifenregion erfährt bei der Bildung des Komplexes mit dem Aminoglycosid eine große konformationelle Änderung. Dieser neue Bindungsmodus eröffnet zusammen mit der einfachen synthetischen Zu gänglichkeit von Neooligoaminodeoxysaccharid-Derivaten die Möglichkeit, eine neue Klasse von TAR RNA bindenden Molekülen zu entwerfen. Diese könnten gleichzeitig die Bildung des binären Tat/TAR- wie auch des ternären Tar/TAR/CycT1-Komplexes durch Störung der Schleifen- und Bulge-Region der RNA verhindern.

Stichwörter: Aminoglycoside, TAR RNA, NMR, Bindungsmodus

#### Abstract

The formation of the Tat-protein/TAR RNA complex is a crucial step in the regulation of Human Immunodeficiency Virus (HIV)-gene expression. To obtain fulllength viral transcripts the Tat/TAR complex has to recruit the positive transcription elongation factor complex (P-EFTb), which interacts with TAR through its CyclinT1 (CycT1) component. Mutational studies identified the TAR hexanucleotide loop as a crucial region for contacting CyclinT1. Interfering with the interaction between the Tat/CycT1 complex and the TAR RNA is an attractive strategy for the design of antiHIV drugs. Positively charged molecules, like aminoglycosides or peptidomimetics, bind the TAR RNA, disrupting the Tat/TAR complex. Here, we investigate the complex between the HIV-2 TAR RNA and a neooligoaminodeoxysaccharide by NMR spectroscopy. In contrast to other aminoglycosides, this novel aminoglycoside analogue contacts simultaneously the bulge residues required for Tat binding and the A35 residue of the hexanucleotide loop.

Upon complex formation, the loop region undergoes profound conformational changes. The novel binding mode, together with the easy accessibility of derivatives for the neooligoaminodeoxysaccharide, could open the way to the design of a new class of TAR RNA binders, which simultaneously inhibit the formation of both the Tat/TAR binary complex and the Tat/TAR/CyclinT1 ternary complex by obstructing both the bulge and loop regions of the RNA.

Keywords: Aminoglycoside, TAR RNA, NMR, binding mode

## Acknowledgements

This thesis is the culmination of three and a half years of work whereby I have been accompanied and ably supported by many people, who have further strengthened my faith that interdependence is as valuable a virtue as independence is. Looking back, the PhD . has been a challenging yet gratifying and an "eye opening" experience. It is indeed an honor and a pleasure to express my gratitude to those who have been instrumental in my scientific growth and more importantly, in the successful completion of my Ph.D. dissertation.
The first person I would like to thank is my supervisor Teresa Carlomagno. I owe a lot of gratitude for her guidance, insights, constructive criticism and encouragement. I have had the opportunity to learn a lot about the subject under her able supervision.

I am also very grateful to Claudia Schwiegk, who introduced me to the nuances of synthesizing and labeling nucleic acids. Her technical expertise and skill contributed immensely to the success of my research. Sincere thanks to Victor Sanchez Pedregal for having been an excellent coworker and mentor in the initial days of my PhD.
A thanks goes out to Jochen Junker for his generous help with the computational aspects of my work. I shall remain indebted to him for having introduced me to the Apple Mac systems and having helped me broaden my horizons from just the PC to the Mac and Linux based machines. A heartfelt thanks to my colleagues Christophe Fares, Marcel Reese, Jörg Fohrer, Dirk Bockelmann, Marco Mukrasch, Peter Haberz, Ping Li and Volker Klaukien who provided a wonderful environment at work.
Jegannath, Raghav, Madhu, Venkatesh and Kiran added the touch of "Indian"ness to my stay in Göttingen and provided me with the much needed "home away from home" environment. They are friends who's association I shall cherish all my life.

To Kalpana, I owe thanks for being a tremendous source of encouragement and a very special friend who stood by me through thick and thin.

The time spent at the Max Planck has been a knowledge enhancing one and one that allowed me to interact with people from various countries and disciplines. I thank Professor Griesinger who provided me with the financial support that enables me to leave the Max Planck not only enhanced with knowledge, but also enriched culturally. The Max Planck Society, DFG (Deutsche Forschungsgemeinschaft) and SFB (Sonderforschungsbereich) have been gracious with their financial assistance at
various points of my PhD . I owe them thanks for supporting my research and my stay here in Germany.

None of this work would have been possible had it not been for the support, love and encouragement I received from my family. I thank my mother and father for their faith, affection and prayers that fuelled me on towards my goal at times when research seemed too daunting a task. I especially thank my sisters Jaishree and Latha for their loving support. I owe them all a special gratitude for being patient and allowing me to take on this opportunity to do research abroad, while still bearing the angst of separation for extended periods.
Finally, I would like to dedicate this work to my late grandparents who would have been immensely proud to see me get the coveted title of "Dr.".

So long, and thanks for the PhD...

## 1 Introduction

The ultimate goal of therapy for HIV infection is to eradicate the virus. To date, therapeutic agents have only been able to push the virus towards a state of latency. Selected drugs can induce rapid, substantial and sustained viral suppression in some patients. However, recent evidence suggests that even in patients with undetectable levels of HIV RNA in plasma, latent reservoirs of virus exist that may require at least 60 to 70 years of therapy to completely eradicate the virus [ ${ }^{1 ; 2}$ ]. Furthermore, current therapies are limited by problems such as drug resistance, poor drug compliance and long-term side effects. Thus, the search for novel therapeutic options and approaches continues.

Developments in the field of NMR, exemplified by the attainment of higher field strengths, introduction of the cryo probe technology, new alignment media, residual dipolar couplings as a sensitive probe of molecular structure and dynamics and novel labeling strategies have aided immensely in the search for new drugs $[3 ; 4 ; 5 ; 6 ; 7 ; 8]$. In parallel, rapid advances in related fields such as crystallography, microscopy, combinatorial chemistry and computational methods have provided greater momentum to the ongoing search for novel therapeutics. It is now routinely possible to obtain high-resolution structures of essential proteins and nucleic acids that play a key role in the interactions of important processes such as transcription and design new scaffolds that can specifically and effectively target such interactions. The resolution of structures of reverse transcriptase, protease, integrase and gp41 [9;10] has already resulted in new drugs that are either approved for clinical use or in the trial phase [ ${ }^{11}$ ]. Other HIV specific structures such as regulatory protein-RNA interactions such as the Tat-TAR and the Rev, RRE have also simulated rational drug development [ ${ }^{12 ; 13}$ ]. Just thirty years after the identification of the HIV [ ${ }^{14 ; 15}$ ], several antiviral drugs have been licensed and several more are in the process of development to combat this deadly disease.

Administering a concoction of drugs is generally more efficient than treating the disease based on monotherapy. Constant mutation and increasing drug resistance makes monotherapy inefficient. Highly Active Antiretroviral Therapies (HAART) consists of drugs aimed at multiple targets [ ${ }^{16 ; 17}$ ]. Research has proved that HAART can reduce viral replication in the plasma to undetectable levels $(<50$ RNA
copies $/ \mathrm{ml}$ ) sufficient to make the emergence of resistant variants highly unlikely [ ${ }^{16 ;}$ ${ }^{17}$ ]. Further, multi drug resistance has not been detected and hence different drugs can be combined that, though effect the same molecular targets, show a sufficiently different spectrum of escape mutations to prevent cross-resistance [ ${ }^{18}$ ].
Therapeutic techniques based on targeting RNA-protein interactions have attracted focus recently [ ${ }^{19 ; 20 ; 21 ; 22 ; 23 ; 24 ; 25 \text { ]. RNA is involved in many biologically important }}$ processes such as control of gene expression and translation processes. The wide range of conformations that can be adopted by RNA, containing double stranded duplexes, hairpins, loops, pseudo knots, bulges etc. contribute to the structural diversity and functional specificity of secondary structures involved in RNA-protein interactions and cellular functions. Targeting the interaction between the viral Tat protein and the Trans Activation Response element (TAR RNA) is an example of targeting conserved regions and conserved structures in the viral genome [ ${ }^{13 ; 21 ; 26}$ ]. The virus encodes for a positive regulatory gene which is required for replication and increases gene expression directly by the HIV Long Terminal Repeat (LTR) promoter [9;27;28;29]. The TAR element of the HIV-RNA is a structured RNA that binds to a viral nuclear regulatory protein called Tat. Disrupting the binding of Tat to the TAR RNA will thus block viral replication [ ${ }^{10 ; 22 ; 30 ; 31 ; 32 ; 33 ; 34 ; 35 ; 36 ; 37 ; 38 ; 39}$ ]. The 5 '-TAR region of HIV mRNA is highly conserved amongst different HIV isolates and the TAR RNA is a highly conserved structure. The correct Tat/TAR RNA interaction is essential for viral gene expression. Tat also plays an essential role in AIDS pathogenesis and associated malignancies, both as an extra cellular protein [ ${ }^{28 ; 40 ; 41 ; 42 \text {; }}$ ${ }^{43}$ ] and as an activator of cellular gene expression encoding cytokines.
The following sections take a closer look at the structure and function of the TAR RNA, Tat protein and associated bio molecules that govern HIV transcription and replication.

### 1.1 The TAR RNA

The 5 ' end of all HIV mRNAs, whether they are spliced or not, starts with the formation of an identical stem-bulge-loop structure called the Trans Activation Responsive (TAR) element located from nucleotide position +1 to +59 . TAR was originally identified as the target for the trans-activator of HIV, the Tat protein, which is essential for efficient transcription of viral genes and for viral replication [44; 45]. The studies that have examined the structure and the sequence of TAR have shown that the stem structure, the sequence in the bulge and in the loop, as well as the distance between the bulge and the loop are all required for Tat-mediated transactivation $[9 ; 44 ; 46 ; 47 ; 48 ; 49$ ]. The influence of mutations, especially in the bulge and loop region of the TAR RNA has emphasized its functional importance in the context of HIV replication. It has been observed that viral kinetics is affected when mutations causing changes in structure and sequence are inflicted upon the native TAR RNA [ ${ }^{50}$ ]. It is known that there are two varieties of TAR RNA, each one arising from one of the two variants of HIV. TAR-1 differs from TAR-2 only in the presence of an extra nucleotide, C24 in the bulge of TAR-1 while this is absent in the sequence of TAR-2 RNA. Fig 1.4 shows a comparison between TAR-1 and TAR-2 of HIV-1 and HIV-2 respectively.

Fig 1.1(a) A comparison of the sequences of TAR-1 and TAR-2 RNA of HIV. The nucleotides that are vital in the recognition of Tat protein as well as other factors influencing the production of full-length viral transcripts are marked in blue. Only the presence of the nucleotide Cyt-24 in the bulge differentiates TAR-1 from TAR-2 RNA.

The structure of the free TAR RNA has been well characterized by NMR spectroscopy. In summary, the TAR RNA consists of a lower stem region spanning residues 16 to 21 and 41 to 46 , an upper stem region spanning residues 26 to 29 and 36 to 39 , a Uridine rich bulge region that connects the upper stem to the lower (residues 22 to 25 ) and finally a disordered and dynamic hexanucleotide loop atop the upper stem region. The NMR study [ ${ }^{31 ;}{ }^{51}$ ] reveals that both the stems adopt a conformation close to that of an A-form helix. The bulge residues U23 and C24 (HIV1 TAR RNA) remain stacked within the helix while U25 is looped out, resulting in a distortion of the phosphate backbone between C24 and G26. Overall, this results in an accessible and wide major groove making it ready for binding to the important residues of the Tat protein. The residues of the hexanucleotide loop are disordered in the NMR structure of the free TAR RNA. The use of relaxation rates and residual dipolar couplings has further contributed towards the understanding of structure and dynamics of the RNA.

Fig 1.1 Structure of free TAR RNA (b) Superposition of residues 17-21,41-45 (lower stem) of four structures from 20 structures in 1 anr .pdb representing the motional amplitude of the upper stem with respect to the lower stem. (c) Best energy structure of free TAR RNA. Notice that the upper stem does not stack co axially on the lower stem. The backbone has been highlighted in red ribbon and the residues of the flexible hexanucleotide loop are invisible.

Al-Hashimi et al. [ ${ }^{52 ; 53 ; 54}$ ] have extensively analyzed residual dipolar couplings in partially oriented systems and concluded that inter helical amplitude of $46 \pm 4^{\circ}$ is
possible for the TAR RNA in its ground state. A pictorial representation of the motional amplitude in free TAR RNA is shown in Fig 1.1(b) where the lower stems of 4 structures from 1ANR.pdb $\left[{ }^{31}\right]$ have been superimposed. The resulting divergence in the upper helix relative to the lower helix is generally attributed to the flexibility present in the bulge residues 22 to 25 and 40 .

The TAR RNA has been extensively studied in the context of Tat trans-activation, but recent data have shed light on its role in translation and that it is a target for a number of cellular RNA binding proteins that influence the rate of HIV translation (details in Table1). Considering its vital role in the virus life cycle, the HIV TAR RNA has been the target of drug development that has led to small molecules and RNA-based strategies for gene therapy.

|  | Viral Function | Cellular Function |
| :---: | :--- | :--- |
| Tat | HIV trans-activator, binds TAR RNA |  |
| hCycT1 | Binds Tat and increases its affinity for TAR <br> RNA | Cyclin |

| TRBP | Binds TAR RNA and enhances translation | Inhibits PKR, increases cell growth, controls <br> spermatogenesis |
| La autoantigen | Binds TAR RNA and enhances translation | RNAP III transcription |

Table 1. Viral and Cellular Proteins Involved in HIV TAR RNA functions [ $\left.{ }^{44}\right]$

### 1.2 The Tat protein

Lentiviral Tat proteins are small ( $\sim 101$ amino acid long), arginine rich RNA binding proteins encoded by two exons. The amino acids encoded by the first exons are both necessary and functional for TAR RNA binding and in vivo transcriptional activation [ ${ }^{28 ; 40}$ ]. Though an 86-amino-acid shortened version of Tat protein is found in the genome of a few laboratory passaged HIV's, naturally occurring HIV's have a 101-amino-acid Tat protein. An atypical transcriptional activator, Tat protein binds not to DNA but to the specific promoter proximal nascent leader the TAR RNA [ ${ }^{28 ; 42 ; 45 ; 55 ;}$ ${ }^{56 ;}{ }^{57}$ ]. The Tat protein is composed of several functional regions. A cysteine-rich region (amino-acids 22-37) contains seven cysteine residues; a "core" sequence (amino acids 37-48) contains six arginines and two lysines, and a glutamine rich region at the carboxyl terminus of the first exon. Only the basic and core regions are conserved in lentiviruses and although the integrity of the cysteine rich region is essential for transactivation, this region does not appear to be directly involved in TAR RNA recognition. Based on mutational analysis, Tat can be divided into two domains. The first domain is the activation domain (amino acids 1-47) or co-factor binding domain, which is functionally autonomous and is active when recruited to the HIV long terminal repeat (LTR) via heterologous RNA-binding protein. The second functional domain contains the basic region required for both RNA binding and nuclear localization activities of Tat [ ${ }^{58}$ ].

Fig 1.2 The Tat protein genome

### 1.3 The Tat-TAR complex

The TAR RNA was originally localized to nucleotides +1 to +80 within the viral LTR but subsequent deletion studies have established that the region from +19 to +42 incorporates the minimal domain that is both necessary and sufficient for in vivo Tat protein responsiveness. As described in the previous section, TAR RNA consists of a hexanucleotide loop, an upper stem and a lower stem close to an A-form helix separated by a three (or two) nucleotide pyrimidine bulge.
Interactions between Tat protein and cellular co-factor CyclinT1 are necessary for the recognition of TAR RNA. Fluorescence Energy Transfer studies using dye labeled Tat and TAR shows that the affinity of Tat protein to TAR RNA is increased when the human CyclinT1 interacts with the activation domain of Tat protein [ ${ }^{59}$ ]. Biochemical and genetic studies show that Tat and human CyclinT1 interaction requires an essential cysteine (C261 on the CyclinT1 protein) and zinc [ ${ }^{60}$ ], indicating that these proteins may form a metal-dependant heterodimer $\left[{ }^{61}\right]$. Structural studies involving NMR, site specific photo cross linking, site specific modification and affinity cleavage analysis have helped to understand the interaction in the Tat-TAR complex and the ternary CyclinT1-Tat-TAR complex. The following points summarize the salient features of Tat-TAR interaction.

1) The TAR RNA element forms a hairpin stem-loop structure with a side bulge; the bulge is necessary for Tat binding and function. Site-specific modification reveals that argininamide can act as an effective Tat mimetic and may reflect on the mechanism that allows Tat protein to specifically bind to the TAR RNA. NMR investigation reveals that in the TAR-argininamide complex, the guanidium group of argininamide forms hydrogen bonds to the major groove face of G26 and is stacked between U23 and A22. This is accompanied by the formation of a base triple between U38, A27 and U23 $\left[{ }^{46 ; 62}\right]$.
2) Unlike the free TAR RNA that exhibits dynamics of the upper stem with respect to the lower stem as depicted in Fig 1.1 (b), in the argininamide bound form of the TAR RNA, the upper stem co axially stacks on top of the lower stem.

Fig 1.3(a) TAR-argininamide binding. Major groove view of argininamide in red binding to TAR RNA (1AKX PDB accession number). The base triple formed by residues U38, A27 and U23 is marked in green. Argininamide is within hydrogen bonding distance to G26 (shown in yellow).
3) Site specific cross-linking and affinity cleaving analysis suggests that in the bound form the residues 42 to 72 of Tat are close to the U42 of TAR RNA [ ${ }^{63}$ ]. Further, Cys 57 of Tat is close to the residue U31 in the loop of TAR RNA. Affinity cleaving experiments also show that F 38 of the Tat protein is located in the proximity of nucleotide 34 and 35 of the TAR RNA. Also, the residue K50 of the Tat protein has been found to cross-link with the TAR nucleotide 34 and the binding of CyclinT1 to the Tat/TAR complex considerably enhances this interaction [ ${ }^{[177}$ ]. Fig 1.3 (b) schematically depicts the contacts between residues on the Tat protein and TAR RNA. The formation of the Tat-TAR complex is important because of the following reasons:
a) Tat protein promotes formation of an activated transcription elongation complex.

Transcription reactions performed using immobilized template DNA carrying wildtype TAR RNA elements in the absence and presence of recombinant Tat protein revealed that the processivity of transcription complexes prepared in the presence of Tat is significantly greater than that of complexes prepared in the absence of Tat [ ${ }^{64 ;}$ ${ }^{65}$ ].
b) Activation of the transcription complex requires recruitment of Tat by a functional

TAR RNA element. Tat activated transcription is strictly dependent upon the presence of a functional TAR RNA element $\left[{ }^{66}\right]$.

Fig 1.3(b) Tat-TAR RNA interaction. A schematic depiction of important residues identified in the interaction between the Tat protein and TAR RNA. Residues 42 to 72 on Tat are close to U42 on the TAR (shown in yellow). Cys57 of the Tat is close in space to the U31 residue in the TAR loop (both shown in red). F38 (magenta) shows crosslink's with residues 34 and 35 on the TAR while K50 is close to G34 on the TAR RNA (shown in blue).
c) Release of TAR RNA from the transcription complex.

The binding of Tat protein is known to induce a conformational change in the TAR RNA. [22; 49; ${ }^{67}$ ] and this in turn may create a recognition site for a cellular co-factor recognizing the TAR apical loop. Karn et al. $\left[{ }^{64}\right]$ propose that loop recognition factors could help dissociate Tat from TAR RNA, displacing the $5^{\prime}$ end of the nascent chain and permitting Tat to bind tightly to RNA polymerase II [ ${ }^{68}$ ]. Thus, the apical loop is an integral part of the process of initial recruitment of Tat protein and subsequent release of the Tat protein to aid in the formation of a Tat-RNA polymerase II complex.

### 1.4 Positive Transcription Elongation Factor b

The positive transcription elongation factor b ( $\mathrm{P}-\mathrm{TEFb}$ ), a general elongation factor was first identified and purified from Drosophila extracts. It acts to prevent RNA polymerase arrest and contains an associated kinase activity capable of hyperphosphorylating the C-terminal domain (CTD) of Rpol II [ ${ }^{69 ; 70 ; 71}$ ]. P-TEFb is composed of two subunits: the catalytic subunit Cyclin-dependent kinase (CDK9) and the regulatory subunit CyclinT1 [9; 72; 73]. Complexes containing CDK9 and CyclinT1-related proteins, CyclinT2a or CyclinT2b, are also active for P-TEFb function [ ${ }^{74}$ ]. Tat interacts with CyclinT1 subunit of P-TEFb and recruits the kinase complex to the TAR RNA. Recruitment of P-TEFb to TAR has been proposed to be both necessary and sufficient for activation of transcription elongation from the HIV1 LTR promoter [ ${ }^{27 ; 75}$ ]. The first 272 residues of human CyclinT1 are sufficient to bind Tat and TAR in vitro and support Tat transactivation in vivo $\left[{ }^{60}\right]$.

### 1.5 The Tat-TAR-CyclinT1 complex interactions

The formation of the Tat-TAR-CyclinT1 complex is a highly concerted and cooperative event. Rana et. al. $\left[{ }^{76}\right]$ investigated the interaction of the TAR RNA and Tat protein in the absence and presence of CyclinT1 (with $\mathrm{Zn}^{2+}$ ) by monitoring the distance and efficiency of energy transfer in a complex formed between chemically synthesized TAR-Fluorescien and Tat-Rhodamine. The efficiency of energy transfer between the Tat protein and TAR RNA was reduced in the presence of CyclinT1 thus suggesting that the Tat protein my go through a structural reorganization upon CyclinT1 binding. Further, in the absence of $\mathrm{Zn}^{2+}$, no energy transfer was detected thus pointing towards the fact that interactions may be via a metal linked heterodimer between the Tat protein and CyclinT1.

The Tat protein binds TAR RNA with a $\mathrm{K}_{\mathrm{D}}$ of 8.2 nM , and this affinity is enhanced ten-fold in the presence of CyclinT1. Additionally, a Tat peptide containing only the arginine rich motif binds TAR RNA with a $K_{D}$ of 1 nm . This increase in binding affinity and the structural rearrangement as suggested by FRET data discussed above help conclude that CyclinT1 enhances the affinity and stability of the Tat-TAR
complex. The TAR RNA loop is of particular significance though the mechanism by which Tat-TAR complex favors the interaction of CyclinT1 with the hexanucleotide loop of the TAR RNA is not known. Photo crosslinking experiments demonstrate that CyclinT1 directly interacts with TAR loop residues 31 and 33 and the U31 side of the loop is the major interaction site. As pointed out in section 1.3, the Tat protein also interacts with the residue 34 side of the TAR RNA loop. Thus, it can be concluded that structural reorganization of the TAR RNA loop may play an important role in the formation and stabilizing of the Tat-TAR-CyclinT1 complex.

### 1.6 Inhibitors of the Tat-TAR interaction

The interaction between Tat and TAR RNA is critical for virus replication. Altering the RNA binding site results in defective viruses and furthermore, the viral replication is strongly inhibited by the over expression of TAR RNA, which acts as a competitive inhibitor of regulatory protein binding. [77]. A Tat agonist may inhibit HIV replication from integrated proviral DNA at an early stage of viral replication. On the other hand, transcriptional regulators, expressed early in the replication cycle (Tat) to control transcription of other viral genes are attractive targets for antiviral agents directed against chronic viral infection $\left[{ }^{20}\right]$. A compound that inhibits the transactivation of the HIV LTR promoter by the viral Tat protein may force the virus to a state of latency. Such compounds may inhibit both acute and chronic HIV infections and they may lead to less resistance. Mutations in the regulators that antagonize the interaction could be potentially lethal to the viruses. Since the viral transcriptional regulators do not have any cellular counterparts, they represent a potentially selective antiviral targets. Furthermore, since the Tat-TAR interaction is highly conserved between virus isolates, anti Tat-TAR drugs are less likely to be affected by HIV variability than other drugs.
The ability to exploit Tat-TAR function for antiviral therapy was first demonstrated by Lisziewicz et al. $\left[\begin{array}{c}78 ; 79 ; 80 ; 81\end{array}\right]$ where a Tat inhibitory gene (anti-Tat) was used to decrease the amount of Tat protein by inhibiting the translation of the Tat mRNA, thus proving its value as an effective long-term suppressor of HIV and also suggesting that anti-Tat gene therapy may be beneficial to block HIV replication and reconstitute the immune system of late phase AIDS patients.

## GENE THERAPY

## DRUGS

Fig 1.6 Interfering with the HIV transcription apparatus. A variety of techniques have been established in recent years to interfere with the Tat-TAR interaction that is crucial for HIV transcription regulation.

The examples summarized in the following sections demonstrate that inhibiting the Tat-TAR interaction might be an interesting approach to inhibit HIV replication and that the arginine-binding site on the TAR RNA (described previously) could be an important interaction site for potential inhibitors.

### 1.6.1 Antisense Oligonucleotides

The concept underlying antisense technology is based on the fact that the use of a sequence, complementary by virtue of Watson-Crick base-pair hybridization, to a specific mRNA can inhibit its expression and thus induce a blockade in the transfer of genetic information from DNA to protein. Antisense oligonucleotides are unmodified or chemically modified single-stranded DNA molecules. In general, they are relatively short (13-25 nucleotides) and hybridize to a unique sequence in the total pool of targets present in cells. A novel, and potentially remarkable, development in oligonucleotide technology is the relatively recent finding that 21 to 23-mer doublestranded RNA molecules, known as siRNA, can effectively silence gene expression. Other antisense oligonucleotide technologies worth a mention are the use of 12 to 16mer 2'-O-methyl oligoribonucleotides binding to the TAR RNA and inhibiting the binding of Tat protein in the 20 to 100 nM range [ ${ }^{33}$ ]. These oligonucleotides are complementary to the HIV TAR RNA apical stem loop and bulge region.

### 1.6.2 Cationic peptides

A second series of compounds that have been used to target the Tat-TAR interaction are the cationic peptides. Research has confirmed that Tat peptide binding to TAR RNA can be inhibited by L-argininamide and agmatine although the $\mathrm{K}_{\mathrm{i}}$ value for both these molecules is high [ ${ }^{82 ;}{ }^{83}$ ]. Tat mimetics have been designed from the basic domain of the Tat protein specific for the TAR RNA. Noteworthy examples are Tat-9K-biotin, Tat10-biotin, and CGP 64222 etc.

Fig 1.6.2 CGP 64222

### 1.6.3 Intercalators

A third series of compounds targeting the Tat-TAR interaction are intercalating agents, often combined with cationic groups. Most commonly, an ethidium derivative composed of arginine, a linker and an ethidium is employed to inhibit the Tat-TAR interaction. Molecular modeling studies show that the ethidium seems to fit near an unpaired residue at position 17 while the arginine side chain occupies the pyrimidine bulge at position 23-25 [ $\left.{ }^{84 ; 85 ; 86}\right]$.

### 1.6.4 Aminoglycosides

The aminoglycosides are a clinically important group of antibiotics that have a broadspectrum of activity and that are bactericidal in action. The family includes streptomycin, gentamicin, neomycin tobramycin, kanamycin, amikacin and netilmicin. Since the discovery of streptomycin, the first aminoglycoside to be isolated by Waksman and co-workers [ ${ }^{87 ; 88}$ ]; the role of aminoglycoside antibiotics as a family of RNA binders has been considerably accentuated by reports from Schroeder et al. and Green et al. who demonstrated the capability of these antibiotics to inhibit splicing in group I introns and interaction between the HIV-1 Rev protein and its RNA target respectively [ ${ }^{89 ; 90}$ ]. Consequently, aminoglycosides have become a vital tool in targeting and inhibiting the interaction of Tat protein and TAR RNA in the HIV virus. They also offer a powerful tool to study the structural basis of RNA recognition and inhibition of function by cationic organic molecules in general.
Aminoglycosides have a variety of effects within the bacterial cell but principally they inhibit protein synthesis by binding to the 30 S ribosomal subunit to prevent the formation of an initiation complex with messenger RNA. They also cause misreading of the messenger RNA message, leading to the production of nonsense peptides. Another important function of the aminoglycosides is that they increase membrane leakage.
The common core of most aminoglycosides is 2-Deoxystreptamine (2-DOS), a highly functional aminoglycositol. Glycosylation of the 2-DOS core (Figure 1.6.4), typically at the 4- and 5-, or 4- and 6- positions characterizes most aminoglycosides. Examination of binding affinities reveals some rudimentary structure activity
relationships in aminoglycosides. The importance of amino groups for RNA binding and inhibition is apparent.

Fig 1.6.4 2- Deoxystreptamine

Also evident from affinity data is that, hydroxyl groups influence RNA affinity. Changing an amino group to a hydroxyl group in kanamycin A abolishes inhibitory activity in self-splicing and Rev-RRE assays $\left[{ }^{24}\right]$. Thus, it can be concluded that electrostatics plays an important role in RNA affinity. Despite apparent disadvantages like unspecific binding, high toxicity and rapid development of bacterial resistance, novel aminoglycosides are a valuable instrument in combating diseases especially related to Gram-positive bacteria, interfering with crucial RNA-protein interaction and in understanding the fundamental characteristics of RNA recognition. The main theme of research undertaken in this thesis is concerned with the interaction of the TAR RNA with a novel macro cyclic 1,4-butanediol-linked aminodeoxyglucoside; henceforth referred to as AMG and the preparation of which has been described by Kirschning et al. ${ }^{\left[{ }^{91}\right] \text {. }}$

### 1.7 Scope of the work and the questions we address

RNA can adopt a plethora of conformations, depending on factors such as pH , temperature and salinity and hence, monitoring and studying the changes in local and global conformations of RNA has become increasingly important to understand principles of RNA recognition and RNA-protein interactions. These changes in conformation are usually triggered by cofactors that are required for biological functions.

As described in previous sections, small positively charged molecules such as polyamines, aminocyclitols and aminoglycosidic scaffolds can specifically recognize the three dimensional motifs of RNA and thus arrest the RNA in a biologically inactive conformation or compete directly with the binding of proteins and cofactors that are essential for biological function. A deeper insight into the principle of recognition of RNA with cationic antibiotics represents a major step towards RNA based drug design.

The Tat protein-TAR RNA complex offers a unique model system to investigate the role of such antibiotics on the interaction of RNA-protein systems that are of vital importance for the proliferation and pathogenicity of viral entities such as HIV. Further, the interaction of Tat protein with CyclinT1 unit of the $\mathrm{P}-\mathrm{ETFb}$ complex is a key element in the control of HIV viral replication and constitutes attractive targets for anti viral therapy. The structural investigation carried out as part of this thesis work, of a novel aminoglycoside analogue interacting with the TAR RNA, offers unique insights particularly for the hexanucleotide loop of the RNA and how a better understanding of the multiple possibilities of RNA recognition by a cationic antibiotic can lead to the design of improved TAR binders and pave the way for alternative therapeutic approaches that inhibit the interaction of the TAR RNA with the Tat protein and subsequently the $\mathrm{P}-\mathrm{ETFb}$ complex.

Employing NMR and a variety of biochemical assays to characterize the structure of this novel aminoglycoside (AMG) and the TAR RNA, we aim to shed light on the following key issues:

1) Where does the aminoglycoside bind to the TAR RNA?
2) What effect does the binding of AMG have on the bulge and the disordered hexanucleotide loop of the TAR RNA?
3) Does the binding of AMG to the hexanucleotide loop suggest a possible principle of recognition of CyclinT1 of the same loop?
4) What is the basis of RNA recognition by AMG? Do hydrogen bonds and specific contacts to the phosphate backbone of the TAR RNA influence the recognition of TAR RNA by AMG?

## 2 Methods

### 2.1 HIV-2 TAR RNA synthesis

The HIV-2 TAR RNA sequence is shown in Figure 2.1. The presence of two Guanine nucleotides at the 5 ' end opposed by two Cytosine's at the 3 ' end promotes T7 transcription and prevents aggregation. The RNA was transcribed from DNA templates with T7 RNA polymerase [ ${ }^{92}$ ] expressed and produced in-house. Labeled ${ }^{15} \mathrm{~N} /{ }^{13} \mathrm{C}$ NTPs were purchased from Spectra Stable Isotopes. Table 2.1 shows the components of the reaction.

Test reactions to optimize $\mathrm{MgCl}_{2}$ and NTP concentrations required for the transcription were carried out in $10 \mu 1$ aliquots for both the labeled and unlabeled HIV-2 TAR RNAs. Preparative reactions were subsequently done at the 20 ml scale. All reactions were done in disposable Falcon tubes and extreme care was taken to avoid RNase contamination. The components of Table 2.1 were mixed in the appropriate proportions and the reaction was incubated for 5-6 hours at $37^{\circ} \mathrm{C}$. An amount of EDTA equivalent to the concentration of $\mathrm{MgCl}_{2}$ used was employed to arrest the reaction once the transcription was over. The reaction mixture was extracted once with phenol: $\mathrm{CHCl}_{3}$ and then precipitated overnight with ethanol at $-20^{\circ} \mathrm{C}$. The precipitant was resuspended in loading buffer ( 8 mM Urea $+0.1 \%$ bromophenol blue $+0.1 \%$ xylenol blue) and separated on denaturing $20 \%$ polyacrylamide gels, $40 \mathrm{~cm} x$ 50 cm , run at 50 W for $\approx 15$ hours till bromophenol blue had migrated most of the gel. The RNA band was visualized by UV shadowing and cut from the gel. Appropriately sized gel slices were electro eluted in an Elutrap apparatus. The resulting elutant was lyophilized and resuspended in appropriate buffer ( 50 mM phosphate buffer and pH 6.4) and the concentration of RNA was estimated by measuring the absorbance at 260 nm .

Figure 2.1 The HIV-2 TAR RNA sequence

| Component |  |
| :---: | :---: |
| NTP <br> (Spectra Stable Isotopes) | $15 \mathrm{mM}(3.75 \mathrm{mM}$ each $)$ |
| $\mathrm{MgCl}_{2}$ <br> (Fluka Biochemika) | 35.00 mM each $)$ |
| T7 polymerase <br> (produced in-house) | 30 mM |
| PEG | $3 \mu \mathrm{l}$ |
| DTT (100mM) | $0.16 \mu \mathrm{l}$ |

Table 2.1 In-vitro T7 transcription reaction components for producing labeled and unlabeled HIV-2 TAR RNA. Optimized NTP and $\mathrm{MgCl}_{2}$ concentrations for unlabeled RNA are shown in red font. The reaction mixture was made up to $10 \mu \mathrm{l}$ by the addition of 10 X buffer which consisted of 400 mM Tris $/ \mathrm{HCl}$ at $\mathrm{pH} 8.0,10 \mathrm{mM}$ Spermidine, 50 mM DTT and $0.1 \%$ Triton-X 100. Preparative reactions were scaled to 20 ml using similar conditions.

### 2.2 Cyclic Aminoglycoside AMG

A short scheme illustrating the summary of the synthesis of AMG as described by Kirschning et. al. $\left[{ }^{91}\right]$ is detailed below:

Fig 2.2 Synthesis of AMG as described by Kirschning et. al [ ${ }^{91}$ ].

The synthetic scheme of the AMG from a 1,4-butanediol linked $\mathrm{C}_{2}$ symmetric riboseconfigured allyl glycoside is shown above. The ${ }^{15} \mathrm{~N}$-labeled and unlabeled cyclic amino glycoside (AMG) was obtained from the laboratory of Prof. Dr.Andreas Kirschning, Institute of Organic Chemistry, University of Hannover in lyophilized form. A stock solution of AMG was prepared for titration to monitor chemical shift changes of the TAR RNA residues with increasing concentration of AMG. 5 mg of AMG (molecular mass $805,051 \mathrm{~g} / \mathrm{mol}$ ) was dissolved in $5 \mu \mathrm{l}, 50 \mathrm{mM}$ sodium phosphate buffer at pH 6.5 and $95 \mu \mathrm{l}$ distilled water. The pH was adjusted to $6.4-6.5$ by the careful addition of 1 M HCl and 1 M NaOH solutions. The electrode was allowed to equilibrate after each addition for maximum accuracy. A final stock solution of $49.686(\cong 50 \mathrm{mM}), 125 \mu \mathrm{l}$ AMG was obtained.

The important materials used in the course of the production of the samples were affiliated as follows:

| Deuterium Oxide $\mathrm{D}_{2} \mathrm{O}$ | Deutero GmbH (99.9\% purity) |
| :--- | :--- |
| Vacuum pumps | Vakkubrand GmbH |
| Eppendorf cups | Abimed |
| Lyophilizer Loc-1M Alpha | Christ |
| Water | Millipore |
| Heating blocks | neoLab |
| NMR sample tubes | Shigemi Co. LTD |
| Vortex Genie | Scientific Industries |

Table 2.2 Equipment and suppliers

### 2.3 RNase footprinting / Digestion

The Ribonuclease T1 (RNase T1) is an endoribonuclease that specifically degrades single-stranded RNA at guanine residues. It cleaves the phosphodiester bond between $3^{\prime}$-guanylic residues and the $5^{\prime}$-OH residues of adjacent nucleotides with the formation of corresponding intermediate $2^{\prime}, 3^{\prime}$-cyclic phosphates $\left[{ }^{97}\right]$. The reaction products are 3'-GMP and oligonucleotides with a terminal 3'-GMP. The Ribonuclease T1 does not require metal ions for activity. RNase A is sequence specific for single stranded RNAs. It degrades 3 'end of unpaired CYT and URI residues. It cleaves the phosphodiester bond between the 5 'ribose of a nucleotide and the phosphate group attached to the $3^{\prime}$-ribose of an adjacent pyrimidine nucleotide. The resulting 2', $3^{\prime}$ cyclic phosphate is hydrolyzed to the corresponding 3 '-nucleoside phosphate $\left[{ }^{98}\right]$. This experiment is a sensitive probe of residues that are protected and shielded by the presence of AMG and those that are more solvent exposed and susceptible to cleavage/digestion by the respective RNase enzymes.

In summary, residues that are less shielded by the ligand would be more prone to digestion than those residues that are close to the binding site of the ligand and hence protected from digestion.
$10 \mu \mathrm{M}$ of $5{ }^{\prime}-{ }^{32} \mathrm{P}$ labeled HIV-2 TAR RNA was digested with either GUA selective RNase T or URI and CYT selective RNase A [99]. The reaction was performed in autoclaved Eppendorf reaction vessels at $4^{\circ} \mathrm{C}$. The concentration of AMG was varied from $0.1 \mu \mathrm{M}$ to 10 mM . Appropriate controls were performed and extreme precautions were taken to avoid RNase contamination. The reaction was stopped by the addition of 2 mM EDTA and $0.1 \%$ SDS and the reaction mixture was loaded onto a $20 \%$ denaturing polyacrylamide gel. The radioactive complexes were visualized by autoradiography.

### 2.4 PACE (PolyAcrylamide Co Electrophoresis)

The PACE experiment was originally designed to study RNA-protein (peptides) interactions, particularly those complexes with low affinities but this technique can be conveniently extended to investigate the binding of non-protein based ligands to RNA systems. We prepared PACE gels as described by Cilley and Williamson [ ${ }^{100}$ ]. $10 \mu \mathrm{M}$ of 5 , ${ }^{32}$ P labeled HIV-2 TAR RNA and a series of lanes containing different concentrations of AMG ( $0,1,2,5,7,10,20,70,100,200$ and $500 \mu \mathrm{M}$ ) were poured with the native gel ( $15 \%$ acryl amide, 1 X TBE and $0.02 \%$ ammonium persulphate) rotated by $90^{\circ}$.

The gels were run and subsequently visualized by autoradiography and analyzed.
We adapted the PACE experiment to investigate the binding stoichiometry between the TAR RNA and AMG [ ${ }^{101}$ ]. The principle behind this technique warrants a deeper discussion here.

In the analysis of the PACE gel, the RNA is assumed to exist in two distinct states, one is the free unbound state with mobility equal to that of the RNA in the absence of AMG. The mobility of the bound form is a function of the size, shape and charge of the TAR RNA/ AMG complex formed under the given concentration of AMG. Thus, the maximal retardation observed would be system dependent. Also, it is assumed that the bound form and the free form of the TAR RNA are in rapid equilibrium with each other i.e. in the fast exchange regime relative to the electrophoresis time.

The total distance traveled (D) for each TAR RNA under the influence of each AMG concentration considered is measured from the autoradiogram. As a control, the migration distance of TAR RNA in the absence of AMG $\left(\mathrm{D}_{\mathrm{F}}\right)$ is also measured to allow comparison of migration distances of different lanes.

Assuming that a simple binding equilibrium exists between the TAR RNA and AMG leads to

Where $\mathrm{K}_{\mathrm{d}}=[$ TAR] [AMG] / [TAR/AMG], [TAR] is the concentration of TAR RNA and [AMG] is the concentration of the amino glycoside. Further, the fraction of TAR RNA bound to AMG $(\phi)$ is given by

$$
\begin{equation*}
\phi=[\text { TAR }]_{\text {Bound }} /[\text { TAR }]_{\text {Total }} \tag{ii}
\end{equation*}
$$

The binding constant between the TAR RNA and AMG is only moderate; hence it is safe to assume that the concentration of free AMG is equal to the concentration of total AMG. This leads to

$$
\begin{equation*}
\phi=[\mathbf{A M G}]_{\text {Total }} /\left\{\mathbf{K}_{d, \text { app }}+[\mathbf{A M G}]_{\text {Total }}\right\} \tag{iii}
\end{equation*}
$$

Where $\mathrm{K}_{d, \text { app }}$ is the apparent dissociation constant for the TAR/AMG complex under PACE gel conditions. In the absence of AMG, the TAR RNA will travel a distance $D_{F}$ that corresponds to the migration of the free TAR RNA. When the total distance traveled, D equals $\mathrm{D}_{\mathrm{F}}$ then we can conclude that there is no significant interaction between the TAR RNA and AMG complex. A sufficiently high concentration of AMG will lead to maximal retardation of the TAR RNA and this distance $D_{B}$ is indicative of the migration of the fully bound form of the TAR RNA / AMG complex. The fraction of TAR RNA bound at any given AMG concentration is given by

$$
\begin{equation*}
\phi=\left\{\mathbf{D}-\mathbf{D}_{\mathbf{F}}\right\} /\left\{\mathbf{D}_{\mathbf{B}}-\mathbf{D}_{\mathbf{F}}\right\} \tag{iv}
\end{equation*}
$$

Where D is the retardation distance in each lane, $\mathrm{D}_{\mathrm{F}}$ is the retardation distance of the TAR RNA in the absence of AMG and $D_{B}$ is the retardation distance of the TAR RNA completely bound to AMG (in our case at a concentration of $500 \mu \mathrm{M}$ ). Continuing the analysis, substituting (iii) in (iv), we get

$$
\begin{aligned}
& \mathbf{D}=\left\{[\mathbf{A M G}]_{\text {Total }}\left(\mathbf{D}-\mathbf{D}_{\mathbf{F}}\right) / \mathbf{K}_{d, a p p}+[\mathbf{A M G}]_{\text {Totala }}\right\}+\mathbf{D}_{\mathbf{F}} \\
& \text { Leading to }\left(\mathbf{D}-\mathbf{D}_{\mathbf{F}}\right) /\left(\mathbf{D}_{\mathbf{B}}-\mathbf{D}_{\mathbf{F}}\right)=[\mathbf{A M G}] / \mathbf{K}_{d, a p p}+[\mathbf{A M G}]
\end{aligned}
$$

For our investigation of binding stoichiometry in the TAR RNA/AMG complex, we assumed different binding models with different stoichiometries of the TAR RNA in complex with AMG and the theoretical dependence of $\phi$ on the concentration of AMG was calculated in each case from the molar fractions assuming constant concentration of AMG in each lane. The experimental data were fitted to the theoretical function using MATLAB.

The following six different models were considered:
(i) One molecule of the TAR RNA binds to one molecule of AMG
(ii) One molecule of the TAR RNA binds to two molecules of AMG with the same $K_{d}$
(iii) Two molecules of the TAR RNA bind to one molecule of AMG.
(iv) One molecule of TAR RNA binds to two molecules of AMG with different $K_{d}$
(v) One molecule of the TAR RNA binds one molecule of AMG with $\mathrm{K}_{\mathrm{d} 1}$ followed by dimerization of TAR RNA/AMG complex with $\mathrm{K}_{\mathrm{d} 2}$.
(vi) Two molecules of the TAR RNA bind one molecule of AMG ( $\mathrm{K}_{\mathrm{d} 1}$ ). Subsequently two molecules of AMG are recruited by the RNA dimer $\left(\mathrm{K}_{\mathrm{d} 2}\right)$ for a total binding of two TAR RNA molecules and three AMG molecules.

The values of $\mathrm{D}, \mathrm{D}_{\mathrm{B}}$ and $\mathrm{D}_{\mathrm{F}}$ is elucidated from the PACE gel and the concentration of AMG is specific to each lane, hence the apparent $K_{d}$ can be calculated by plotting $\left(D-D_{F}\right) /\left(D_{B}-D_{F}\right)$ vs. [AMG]. Thus, the theoretical dependence of $\left(D-D_{F}\right) /\left(D_{B}-D_{F}\right)$ on the concentration of AMG can be predicted for each of the above mentioned model cases assuming that the concentration of AMG remains constant in each lane.

### 2.5 NMR spectroscopy

The labeled and unlabeled HIV-2 TAR RNA produced by T7 transcription was dialyzed extensively against NMR buffer [ ${ }^{92}$ ].

For the titration of the TAR RNA with AMG, 2.317mg of unlabelled HIV-2 TAR RNA was dissolved in $250 \mu 1$ of $\mathrm{H}_{2} \mathrm{O}$ and $20 \mu \mathrm{l}$ of $\mathrm{D}_{2} \mathrm{O}$. AMG was titrated in varying concentrations steps of molar ratio (TAR RNA: AMG) 1:0, 1:1, 1:2, 1:5, 1:10, 1:20, 1:40, 1:50, 1:70 and 1:100. The effect was monitored on the imino region of the TAR RNA employing a 1 D Watergate experiment $\left[{ }^{[102}\right.$ ] on the 700 MHz Avance spectrometer at 298 K . For the chemical shift mapping, AMG was titrated in concentrations varying from 0.3 mM to 30 mM against a sample of 0.3 mM sample of ${ }^{15} \mathrm{~N} /{ }^{13} \mathrm{C}$-labeled HIV-2 TAR RNA, dissolved in $\mathrm{H}_{2} \mathrm{O} / \mathrm{D}_{2} \mathrm{O}$, containing 50 mM phosphate buffer at pH 6.4 .
The chemical shift changes of both the base ( $\mathrm{C} 5-\mathrm{H} 5, \mathrm{C} 6-\mathrm{H} 6, \mathrm{C} 8-\mathrm{H} 8$ ) and the sugar ( C 1 '- H 1 ') resonances of the RNA were monitored in ${ }^{13} \mathrm{C}$-HSQC spectra $\left[{ }^{103}\right]$ during the titrations on a 600 MHz Avance spectrometer at 298 K . Each spectrum, on the base and sugar was acquired for a total of 5 hours with the acquisition dimensions being 128 points $\left({ }^{13} \mathrm{C}\right)$ and 2048 points $\left({ }^{1} \mathrm{H}\right)$. For the final experiments 0.772 mg of ${ }^{15} \mathrm{~N} /{ }^{13} \mathrm{C}$-labeled HIV-2 TAR RNA $(0.3 \mathrm{mM})$ and 0.724 mg of AMG $(3 \mathrm{mM})$ were dissolved in either $\mathrm{D}_{2} \mathrm{O}$ or $\mathrm{H}_{2} \mathrm{O} / \mathrm{D}_{2} \mathrm{O}(90 / 10 \%)$ containing 50 mM phosphate buffer at pH 6.4. All experiments were acquired in-house on Bruker 600 DRX, 600 Avance, 700 Avance, 800 DRX and 900 Avance spectrometers. All spectrometers except the 600 DRX were equipped with a cryoprobe. The carrier frequency was set to 4.7 ppm $\left(\mathrm{H}_{2} \mathrm{O} / \mathrm{HDO}\right)$ for proton and 148 or 79 ppm for ${ }^{13} \mathrm{C}$ depending on the chemical shifts to be observed. All spectra were collected at 298 K unless otherwise specified. Spectra acquired were transferred and processed using XwinNMR (Bruker, Karlsruhe, Germany) or Felix (MSI).

### 2.5.1 Resonance assignment of the TAR RNA

Standard NMR methods were employed to assign the TAR RNA AMG complex [ ${ }^{104 ;}$ ${ }^{105 ;}{ }^{106}$. One of the fundamental problems in NMR of RNA is obtaining the unambiguous and complete resonance assignment of the spin systems of the ribose sugars that are overlapped due to severe degeneracy of proton and carbon chemical shifts. The 3D HCCH-COSY-TOCSY experiment [ ${ }^{107}$ ] offers an elegant way of combining the benefits of the HCCH-COSY [ ${ }^{108 ;}{ }^{109}$ ] and HCCH-TOCSY [ ${ }^{110 ;}{ }^{111}$ ] experiments and was used to get a complete spin assignment of the ribose spin system of the TAR RNA (C1'-H1', C2'-H2', C3'-H3', C4'-H4' and C5'-H5'/H5', correlations). This experiment was acquired on the 700 MHz Avance spectrometer at 298 K . The acquisition dimensions were 128 points on ${ }^{1} \mathrm{H} / \mathrm{F} 1,64$ points on ${ }^{13} \mathrm{C} / \mathrm{F} 2$ and 1024 points on ${ }^{1} \mathrm{H} / \mathrm{F} 3$, with 20 scans. The following section describes the 3D HCCH COSY-TOCSY (Fig 2.5.1 a) experiment in further detail.

Figure 2.5.1 (a). The 3D HCCH-COSY-TOCSY pulse scheme for the assignment of the ribose sugar of nucleic acids.

The pulse sequence can be divided into 7 parts namely INEPT, the COSY step, followed by the CT period, then the TOCSY mixing, two successive INEPT steps and finally the detection and acquisition.
The effect of the pulses on the ribose spin system can be analyzed using product operator formalism [ ${ }^{112}$ ] as follows:
The INEPT step first creates a proton ( $\mathrm{H}^{\prime}$ ) antiphase magnetization $2 \mathrm{H}^{\prime}{ }_{\mathrm{x}} \mathrm{C}^{\prime}{ }_{\mathrm{z}}$. Coherence is subsequently transferred to the directly attached hetero nucleus ${ }^{13} \mathrm{C}\left(\mathrm{C}^{\prime}\right)$ and results in $2 \mathrm{H}^{\prime} \mathrm{z}^{\prime}{ }^{\prime}{ }_{\mathrm{y}}$.

The COSY step is used to identify coupled spin systems. The $\mathrm{J}_{\mathrm{H}-\mathrm{C}}$ coupling evolves for a period of $2 \Delta_{1} . \Delta_{1}$ is set to $1 / 8 \mathrm{~J}_{\mathrm{CH}}$ where $\mathrm{J}_{\mathrm{CH}}$ is the one bond J coupling constant of ${ }^{1} \mathrm{H}-{ }^{13} \mathrm{C}(\approx 160 \mathrm{~Hz})$. As a consequence, in phase terms of both CH (namely $\mathrm{C} 1{ }^{\prime} / \mathrm{H} 1$ ', $\mathrm{C} 2^{\prime} / \mathrm{H} 2^{\prime}, \mathrm{C} 3^{\prime} / \mathrm{H} 3^{\prime}$ and $\mathrm{C} 4^{\prime} / \mathrm{H} 4$ ') and $\mathrm{CH}_{2}$ (in RNA only $\mathrm{C} 5^{\prime} / \mathrm{H} 5^{\prime}$ and $\mathrm{H} 5^{\prime}$ ) are refocused. Importantly, during the COSY step, the $\mathrm{J}_{\mathrm{C}^{\prime}-\mathrm{C}^{\prime \prime}}$ couplings evolve for a period of $2 \Delta_{3}$. Here magnetization is transferred from C' to the neighboring C'" yielding terms of the form:

$$
\mathrm{C}^{\prime}{ }_{\mathrm{X}} \cos \left(\omega_{\mathrm{H}} \mathrm{t}_{1}\right) \cos \left(2 \Delta_{3} \pi \mathrm{~J}_{\mathrm{C}-\mathrm{C}}\right) \text { and } \mathrm{C}^{\prime}{ }_{\mathrm{y}} \mathrm{C}^{\prime}{ }^{\prime}{ }_{\mathrm{z}} \cos \left(\omega_{\mathrm{H}} \cdot \mathrm{t}_{1}\right) \sin \left(2 \Delta_{3} \pi \mathrm{~J}_{\mathrm{C}-\mathrm{C}}\right)
$$

During the CT (Constant Time), the chemical shift of carbon ( $\omega_{\mathrm{C}}$, and $\omega_{\mathrm{C}}$, ) is modulated by the time period $\mathrm{t}_{2}$ while the $\mathrm{J}_{\mathrm{CC}}$ is modulated by the time period $2 \mathrm{~T}_{\mathrm{C}}$. The detectable terms after the CT are

$$
\begin{align*}
& C^{\prime} x \cos \left(\omega_{l} t_{1}\right) \cos ^{n}\left(2 \Delta_{3} \pi J_{c-c}\right) \cos \left(\omega_{c} \cdot t_{2}\right) \cos ^{n}\left(2 T_{c} \pi J_{c-c}\right) \ldots(\mathrm{a}) \\
& C^{n} x \cos \left(\omega_{A} t_{1}\right) \cos ^{n-1}\left(2 \Delta_{3} \pi J_{c-c}\right) \sin \left(2 \Delta_{3} \pi J_{c-c}\right) \cos \left(\omega_{c} \cdot t_{2}\right) \ldots(\mathrm{b})  \tag{b}\\
& \cos ^{m-1}\left(2 T_{c} \pi J_{c-c}\right) \sin \left(2 T_{c} \pi J_{c-c}\right)
\end{align*}
$$

Where n is the number of carbons attached to $\mathrm{C}^{\prime}$ and m is the number of carbons attached to C'. In case of RNA, it is to be borne in mind that " $m$ " and " $n$ " can take values of either 1 or 2 depending on the number of neighbors the C atom has. C 1 ' and C5' have only one neighboring C atom namely $\mathrm{C} 2^{\prime}$ and C 4 ' respectively, while $\mathrm{C}^{\prime}$ ', C3' and C4' have 2 neighbors each. From the above two terms (a) and (b) we can conclude that the proton $\left(\mathrm{H}^{\prime}\right)$ is correlated to the carbon it is directly attached to ( $\mathrm{C}^{\prime}$ ) and the carbon two bonds away ( $\mathrm{C}^{\prime \prime}$ ). This magnetization is then transferred to all the attached carbons within the ribose spin system in the TOCSY step by a DIPSI-3 mixing scheme $\left[{ }^{[13}\right]$. The reverse inept after the TOCSY step transfers the magnetization from $\mathrm{C}^{\prime}{ }_{\mathrm{X}}$ to $\mathrm{H}^{\prime}{ }_{\mathrm{X}}$ leading to detection on the proton dimension.
In the HCCH-TOCSY experiment, all the ${ }^{1} \mathrm{H}$ or ${ }^{13} \mathrm{C}$ in the ribose system are correlated through the ${ }^{13} \mathrm{C}$-mixing scheme whereas in the HCCH-COSY experiment only the two neighboring ${ }^{1} \mathrm{H},{ }^{1} \mathrm{H}$ or ${ }^{13} \mathrm{C},{ }^{13} \mathrm{C}$ are correlated. Contrarily, the 3D HCCH-COSY TOCSY experiment combines both the transfer schemes into one experiment and offers a powerful technique to resolve whole ${ }^{1} \mathrm{H}-{ }^{13} \mathrm{C}$ COSY patterns for the assignment of poorly dispersed RNA ribose spins.
Further resonance assignment of fully ${ }^{15} \mathrm{~N} /{ }^{13} \mathrm{C}$ labeled RNA is mainly based on a set of heteronuclear through-bond transfer experiments correlating the nuclear spins within the same sugar, the same base, or between the sugar and base of the same
nucleotide [ ${ }^{[04 ; 114}$ ]. For large RNAs (30 nucleotides and higher), especially at lower sample concentration, the inter-nucleotide through-bond HCP correlation experiment $\left[{ }^{115}\right]$ becomes very inefficient and thus, the ${ }^{13} \mathrm{C}$ edited 3D NOESY becomes very important to detect ${ }^{1} \mathrm{H}^{-1} \mathrm{H}$ NOEs between the sugar protons H 1 ', H 2 ' and the aromatic base protons, H 6 or H 8 of sequential nucleotides.
A 3D ${ }^{13} \mathrm{C}$-HSQC NOESY [ ${ }^{116}$ ] (mixing time of 100 ms , acquisition dimensions of 2048 points on $\mathrm{F} 3 /{ }^{1} \mathrm{H}$, 88 points on $\mathrm{F} 2 /{ }^{1} \mathrm{H}$ and 168 points on $\mathrm{F} 1 /{ }^{13} \mathrm{C}$, with 8 scans at 298 K on 800 MHz ) and a base resolved/selective $3 \mathrm{D}{ }^{13} \mathrm{C}$-HSQC NOESY $\left[{ }^{117}\right]$ (mixing time of 100 ms , acquisition dimensions of 2048 points on F3/ ${ }^{1} \mathrm{H}$, 96 points on $\mathrm{F} 2 /{ }^{1} \mathrm{H}$ and 256 points on $\mathrm{F} 1 /{ }^{13} \mathrm{C}$, with 8 scans at 298 K on 800 MHz ) was used for sequential resonance assignment of the TAR RNA. The pulse sequence of the base resolved/selective $3 \mathrm{D}{ }^{13} \mathrm{C}$-HSQC NOESY is shown in Fig 2.5.1 (b) and the effect of the pulses on the RNA can be analyzed as follows:

Figure 2.5.1 (b). The 3D Base Selective NOESY pulse scheme for the sequential resonance assignment of nucleic acids [ ${ }^{117}$ ].

The experiment begins with an initial INEPT step at A, which allows the transfer of
${ }^{1} \mathrm{H}$ magnetization into two-spin order.
The step at B functions as a base type selective C-C filter sequence to separate the resonances of C 8 in purines and C 6 in pyrimidines where the filter delay $\delta$ was set to $1 / 2 \mathrm{~J}_{\mathrm{C} 5 \mathrm{C} 6}$.
This is followed by the carbon evolution period $\left(\mathrm{t}_{1}\right)$ when the ${ }^{13} \mathrm{C}$ spins are frequency labeled while decoupling homonuclear $\mathrm{C}-\mathrm{C}$ scalar coupling. No decoupling is applied
on the ${ }^{1} \mathrm{H}$ dimension so that $\mathrm{H}^{\alpha}$ and $\mathrm{H}^{\beta}$ states are not interconverted. Applying an $180^{\circ}$ pulse on the ${ }^{15} \mathrm{~N}$ dimension removes scalar coupling evolution between base carbons and nitrogen at time $t_{1} / 2$.

The block D performs spin-state-selective coherence transfer from ${ }^{13} \mathrm{C}$ to ${ }^{1} \mathrm{H}$

$$
\mathrm{C}^{+} \mathrm{H}^{\beta} \rightarrow \mathrm{C}^{\alpha} \mathrm{H}^{+}
$$

During $\mathrm{t}_{2}$ in block E, the ${ }^{1} \mathrm{H}$ spins are frequency labeled followed by a NOESY mixing time of 100 ms . The carbon spins are decoupled during $\mathrm{t}_{2}$.
The ${ }^{1} \mathrm{H}$ FID is detected while simultaneously decoupling ${ }^{13} \mathrm{C}$ during F .
This experiment helped correlate $\mathrm{H} 6 / \mathrm{H} 8-\mathrm{H} 1$ ' and $\mathrm{H} 6 / \mathrm{H} 8-\mathrm{H} 2$ ' connectivity's on the TAR RNA residues.

To measure hydrogen bond mediated $\mathrm{J}_{\mathrm{NP}}$ couplings, ${ }^{15} \mathrm{~N}$ labeled AMG was mixed with unlabeled TAR RNA. This was done to exclude or confirm the presence of hydrogen bonding between the amino groups of AMG and the phosphate backbone of the TAR RNA. The J-quantitative method [ ${ }^{118}$ ] was employed to measure the $\mathrm{J}_{\mathrm{NP}}$ couplings in an H-N 2D correlation. The ${ }^{15} \mathrm{~N}$ chemical shift of the amino group confirmed that all four groups of AMG are protonated in the NMR buffer. Since the ligand is in fast exchange with the solvent, the resonances of the amino protons could not be observed.

### 2.5.2 Resonance assignment of the Aminoglycoside

To obtain the resonance assignment of the ligand AMG [ ${ }^{119}$ ], we relied on the following experiments measured on the 600 MHz Avance.
(a) DQF-COSY: 512 points on F1 and 2048 points on F2 with 108 scans
(b) TOCSY: 512 points on F1 and 2048 points on F2, mixing time 20 ms , 48 scans
(c) TOCSY: 512 points on F1 and 2048 points on F2, mixing time $60 \mathrm{~ms}, 48$ scans
(d) NOESY: 512 points on F1 and 2048 points on F2, mixing time 130 ms , 80 scans
(e) NOESY: 384 points on F1 and 2048 points on F2, mixing time 60 ms , 56 scans

Fig2.5.2 The 1D region of AMG.

### 2.5.3 Titrations and chemical shift mapping

An easy and rapid way to gain qualitative information about the interaction between two molecules is to study the chemical shift values. Chemical shifts depend on the local environment. The chemical shifts of ${ }^{1} \mathrm{H}$ and ${ }^{13} \mathrm{C}$ are particularly sensitive to changes of the environment. Therefore ${ }^{1} \mathrm{H}$ and ${ }^{13} \mathrm{C}$ are chemical shift perturbations recorded via ${ }^{13} \mathrm{C}$-HSQC spectra throughout an NMR titration are commonly combined in order to map a binding site of the ligand on an RNA. The residues exhibiting the largest ${ }^{1} \mathrm{H}$ and ${ }^{13} \mathrm{C}$ chemical shift changes upon titration of the ligand define the binding interface.

Fig 2.5.3. Scheme (A) follows the stepwise addition of AMG to 0.9 mM TAR RNA in varying molar ratios, on a 1 D Watergate experiment at 298 K on 700 MHz Avance. Scheme (B) shows the superposition of the base region of a ${ }^{13} \mathrm{C}^{1} \mathrm{H}$ correlation for the HIV-2 TAR RNA free (black) and in complex with AMG (red). Acquisition dimensions were $128\left({ }^{13} \mathrm{C}\right)$ and 2048 points $\left({ }^{1} \mathrm{H}\right)$ each spectrum acquired for 5 hours on a 600 MHz Bruker Avance.

As described in Section 2.5, the chemical shifts of the TAR were monitored on the 1D Watergate experiment and the ${ }^{13} \mathrm{C}-\mathrm{HSQC}$ during the titration against AMG.

### 2.5.4 T 1 relaxation rate measurement

NMR spectroscopic methods can be used to probe motions over a variety of timescales. Autocorrelation ( $\mathrm{T}_{1}, \mathrm{~T}_{2}, \mathrm{~T}_{1 \rho}, \mathrm{NOE}$ ) and cross-correlated relaxation measurements can be used to monitor motions on the ns-ps timescale [ ${ }^{120}$ ].
Relaxation is induced by field fluctuations that occur due to molecular motion, i.e. changes in the local fields as the molecule moves. Thus, NMR relaxation experiments monitor the magnetic fluctuations arising from these molecular motions.

A variety of parameters are at the disposal of the NMR spectroscopist that can be measured using relaxation experiments. It is common to measure the following relaxation parameters for heteronuclear $H X$ spin systems: $T_{1}$-the spinlattice/longitudinal relaxation time, or the corresponding relaxation rate $\mathrm{R}_{1}=1 / \mathrm{T}_{1} ; \mathrm{T}_{2}$ the spin-spin/transverse relaxation time, or the relaxation rate $R_{2}=1 / T_{2}$. The spinlattice relaxation rate describes the recovery of the longitudinal magnetization to thermal equilibrium - the return of the populations of the energy level of the spin system to the Boltzmann distribution. $\mathrm{T}_{2}$ measures the loss of coherence as individual spins experience slightly different resonance frequency due to inhomogeneities in the local magnetic field.

Relaxation rates can also provide useful insights into the molecular weight and size of the molecule. As molecular weights increase the line broadening that is due to slow molecular tumbling rate increases. Consequently, $\mathrm{T}_{1}$ and $\mathrm{T}_{2}$ relaxation times become shorter, though $\mathrm{T}_{1}$ grows again after reaching a minimum.
In order to measure longitudinal relaxation rate, an inversion recovery experiment is performed, while transverse relaxation rates are measured by CPMG (Carr-Purcell-Meiboom-Gill) experiments, which are essentially a train of $180^{\circ}$ pulses [ ${ }^{121 ; 122}$ ]. The relaxation times $T_{1}$ and $T_{2}$ directly related to spectral densities $\mathrm{J}(\omega)$ that describes the reorientation motions of the bond vector to be studied. The spectral densities are related to the correlation function that defines the motion by a simple Fourier transformation; this correspondence makes it possible to probe bimolecular motions from relaxation measurements. Unlike proteins, where the ${ }^{15} \mathrm{~N}$ atoms of amide residues provide a ready tool for the measurement of relaxation rates and thus give a deeper insight into residue specific dynamics, nucleic acids do not contain as many ${ }^{15} \mathrm{~N}$ atoms. The ones that are present in the bases, the water-exchange properties of the GUA, CYT and ADE $\mathrm{NH}_{2}$ are not conducive to their analysis [ ${ }^{123}$ ]. While the
measurement of ${ }^{15} \mathrm{~N}$ relaxation rates certainly shed light on the motions of base paired GUA and URI residues, they are inadvertently limited and thus it becomes necessary to measure ${ }^{13} \mathrm{C}$ relaxation parameters to gain a deeper insight into the structure and dynamics of the nucleic acid in question.

There is an increasing probability of the formation of multiple binding of ligand or multimerization of the RNA in the presence of high concentration of the ligand. To determine if the TAR RNA retains its monomeric status or whether the presence of the excess ligand encourages dimerization (multimerization), we measured $\mathrm{T}_{1}$ relaxation times $\left[{ }^{124}\right.$ ] of the $\mathrm{C} 8-\mathrm{H} 8 / \mathrm{C} 6-\mathrm{H} 6$ in a ${ }^{13} \mathrm{C}-{ }^{1} \mathrm{H}$ correlation experiment (Fig 2.5.4) using relaxation delays (d8) of $5,10,20,30,40,60,80,100,120,160,200$, $300,400,600,800$ and 1200 ms .

Fig2.5.4 Pulse sequence to measure $T_{1}$ relaxation rate for the TAR/AMG complex

After the INEPT step $\left(\mathrm{H}_{z} \mathrm{C}_{\mathrm{z}}\right)$, a reverse INEPT step ensures that we end up with $-\mathrm{C}_{\mathrm{z}}$ term thus allowing us to measure only the ${ }^{13} \mathrm{C}$ relaxation rates. The delay d 8 is varied systematically in different experiments such that the inverted magnetization on ${ }^{13} \mathrm{C}$ is allowed to undergo longitudinal relaxation. The subsequent steps allow chemical shift evolution of ${ }^{13} \mathrm{C}$ in time period tl and coupling modulated by the time period $2 \tau$ after which the magnetization is transferred from ${ }^{13} \mathrm{C}$ to ${ }^{1} \mathrm{H}$ and detected. The delays are set such that $\tau=1 / 4 \mathrm{~J}_{\mathrm{C}-\mathrm{H}}$.

### 2.5.5 Field induced residual dipolar couplings

NMR structures of RNA molecules are usually less well defined than proteins with similar size and weight. This is because only short range interactions, such as sequential NOEs (intermolecular) and intra base pair NOEs, and dihedral angles as elucidated from J-coupling constants are utilized while long range distance information remain sparse or absent. In such circumstances, residual dipolar couplings become an invaluable source of long-range distance and angle information. Under conditions of isotropic tumbling of molecules, the RDCs average to zero and hence this valuable information is lost. To prevent this, several methods to induce partial alignment of the biomolecule in question (in our case RNA) have been introduced, prominent among them filamentous Pf1 bacteriophages, bicelles, Otting phase [ ${ }^{125}$ ] and more recently polyacrylamide gels [ ${ }^{126}$ ].

However, the simultaneous presence of the negatively charged TAR RNA and an excess of positively charged AMG deterred us from using phages [ ${ }^{127 ;}$ 128; ${ }^{129}$ ] or bicelles [ ${ }^{130 ;}{ }^{131}$ ] to attempt the alignment of TAR RNA/AMG complex. Instead, we exploit the natural anisotropic magnetic susceptibility inherent in most molecules, which can lead to partial alignment in a magnetic field [ ${ }^{132 ;}{ }^{133}$ ]. This alignment is substantial for experimental investigation only at high field strength and even then is extremely small (between 0 to 10 Hz ). We exploit this property of dipolar couplings scaling linearly with the square of the field strength $\left[{ }^{134 ; 135}\right]$ and measure the splitting (J+D) of the C2-H2, C6-H6, C8-H8 and C1'-H1' at 600, 700 and 800 MHz . The field-induced residual dipolar couplings ( $f i \mathrm{RDCs}$ ) at 800 MHz were derived by linear fitting of the three values against the square of field strength and extrapolated to zero magnetic field to obtain the value of J (Igor Pro 5 Wavemetrics, Inc). The couplings were extracted from coupled and decoupled version of the ${ }^{13} \mathrm{C}$-HSQC experiments. At higher field strengths, the anti TROSY component of the coupled spectrum becomes much weaker (broad) because of the fast decay of the ${ }^{13} \mathrm{C}$ component; therefore the J+D coupling as given by the difference between the TROSY and anti TROSY peak of the coupled spectrum cannot be accurately measured.

By measuring the difference between the distance of the coupled and the corresponding decoupled peaks, an estimate of half the J+D coupling at particular field strength can be made within appropriate error limits. A macro written in Felix
assisted in shifting and overlaying 1D slices of the coupled and decoupled spectra (Appendix C).

Fig 2.5.5 On the left is a coupled peak whose splitting corresponds to ${ }^{1} \mathrm{~J}_{\mathrm{HC}}+\mathrm{D}_{\mathrm{HC}}$ on the $\omega_{1}$ dimension. On the right is the corresponding peak in the decoupled version of the experiment.

Only those $f i$ RDCs that showed a linear relationship to $\mathrm{B}_{0}{ }^{2}$ within the experimentally determined error limits were employed in a subsequent refinement procedure.

### 2.5.6 NOE distance restraints

Inter and intra nucleotide distance constraints were extracted from a $3 \mathrm{D}{ }^{13} \mathrm{C}$-HSQC NOESY (mixing time 100 ms ) and a base resolved/selective $3 \mathrm{D}{ }^{13} \mathrm{C}$-HSQC NOESY (mixing time 100 ms ). Peak intensities were scored as strong, medium and weak using contour levels to maintain consistency. Intermolecular distance restraints were obtained from a ${ }^{13} \mathrm{C}$-edited $/{ }^{12} \mathrm{C}$-filtered HSQC-NOESY [ ${ }^{136 ;}{ }^{137}$ ] spectrum acquired in $\mathrm{D}_{2} \mathrm{O}$ with a mixing time of 200 ms where the NOEs between the ${ }^{13} \mathrm{C}$-labeled TAR RNA and unlabeled AMG could be selectively observed.

The NOE peak intensities were converted into appropriate NOE distance restraints with upper bounds of $3 \AA$ for strong intense peaks, $4.0 \AA$ for medium intense peaks and $5.0 \AA$ for weakly intense peaks. Very weak NOEs to exchangeable protons or very weak intermolecular NOEs were allowed an upper bound of 6.0 Å.

Table 2.5.6 Intermolecular connectivity's of RNA residues to the ligand as observed in a ${ }^{13} \mathrm{C}$ edited $/{ }^{12} \mathrm{C}$-filtered HSQC-NOESY spectrum. The sugar moiety of the ligand is referred to as "A" and the linker moiety is referred to as " $B$ " in this table.

The intermolecular NOE data has been summarized in Table 2.5.6. The nomenclature of the protons can be understood from Figure 2.5.6(a).

Given that the ligand AMG has a two-fold symmetry and a four-fold degeneracy of its resonances, a preliminary intermolecular data set with full ambiguity among the four possibilities was evaluated. To arrive at a more appropriate intermolecular data set, a rigorous and exhaustive procedure was adopted to define intermolecular NOEs spanning all reasonable possibilities that are not equivalent by symmetry.

The procedure began by numbering the sugars and linkers of AMG from 1 to 8 in the clockwise direction to define a ring consisting of sugar 1, linker 2, sugar 3, linker 4, sugar 5 , linker 6 , sugar 7 and linker 8 (Fig 2.55 b).

Seven data sets spanning all reasonable possibilities equivalent by symmetry were made as depicted in Fig 2.5.6 (c).

Two assignments were considered for NOEs stemming from residue A35. In the first possibility A35 NOEs were directed towards sugar 1 and linker 2 (column 2 Fig 2.5.5 (b)) while in the second possibility A35 NOEs were directed towards sugar 1 and linker 8 as shown in column 1. For the NOEs stemming from the bulge residues A22, U23 and U25, three alternatives were devised. a) A22, U23 and U25 contact sugar 5 and linkers 4 or 6 (first row); b) A22, U23 and U25 contact sugars 3 or 5 and linker 4 (second row); c) A22 and U23 contact sugar 5 and linkers 4 or 6 , while U 25 contacts sugar 3 and linkers 2 or 4 (third row). Combination of the two possibilities for NOEs from A35 and with the three possibilities arising from the bulge residues yields a total of 6 intermolecular NOE data sets. In the seventh set (bottom), NOEs stemming from A35 were assigned to sugar 1 and linker 8; those stemming from U25, to sugar 3 or linkers 2 or 4; those stemming from U23, to sugars 3 or 5 and linker 4; those stemming from A22, to sugar 5 and linker 4 or 6 . When a residue contacts two AMG moieties equivalent by symmetry (e.g. linkers 4 and 6 ), those restraints were treated as ambiguous in the structure calculation. Taking into account the two-fold symmetry of AMG, the initial seven sets of intermolecular NOE data sets were duplicated by shifting the sugar and linker numbering by one unit (sugar1 -> sugar3, linker 2 ->
linker 4 etc.). Finally, fourteen unique combinations were used in the restrained Molecular Dynamics protocol.

Fig 2.5.6 (c) Intermolecular NOE data sets scheme. The various cases shown above collectively span all the reasonable possibilities that are not equivalent by symmetry.

### 2.5.7 Dihedral angle restraints

The furanose rings in a nucleic acid are twisted out of plane to minimize non-bonded interactions between their substituents. This phenomenon is called puckering [ $\left.{ }^{138}\right]$.
The sugar pucker determines the shape of the A-helix, whether the helix will exist in the A -form or in the B -form. The five membered rings are for steric reasons not planar (Pitzer tension and Newman strain) because then all bonds would be in the eclipse conformation hence one atom or two are turned out of the plane [ $\left.{ }^{139}\right]$. In the ribo furanose, the plane $\mathrm{C} 1^{\prime}-\mathrm{O} 4^{\prime}-\mathrm{C} 4$ ' is fixed. Endo-pucker means that $\mathrm{C}^{\prime}$ ' or C 3 ' are turned out of this plane into the direction of C5'. Exo-pucker describes a shift in the opposite direction. In RNA we find predominantly the C3'- endo conformation. The sugar pucker was defined as either $\mathrm{C} 2^{\prime}$-endo or C 3 '-endo depending on the J coupling constants between H1' and H2' derived from a 2D-HCCH-E.COSY spectrum ( ${ }^{140}$ ). As shown in Fig 2.5.6 (a), if a ribose sugar adopts a C3'-endo conformation, as is usually the case with A-form backbone geometry, then vicinal couplings between ribose H 1 ' and H 2 ' are typically around 2 Hz and smaller. In contrast, the C 2 '-endo conformation results in larger coupling values of around 6 to 8 Hz . Intermediate values are indicative of exchange between the two conformations and residues exhibiting such coupling values are best left unrestrained.

The H3'-H4' couplings can also be used as a diagnostic tool to determine the pucker. A small value of $\mathrm{J}\left(\mathrm{H}^{\prime}, \mathrm{H} 4^{\prime}\right)$ is indicative of a C2'-endo conformation while a large J (H3', H4') is indicative of a C3'-endo conformation adopted by the sugar pucker.

[^0]The HCCH-E.COSY experiment $\left[{ }^{[140}\right.$ ] enabled us to simultaneously detect the ${ }^{3} \mathrm{~J}_{\mathrm{HH}}$ homonuclear coupling along the $\omega_{2}$ dimension and the ${ }^{1} \mathrm{~J}_{\mathrm{CH}}$ heteronuclear coupling along the $\omega_{1}$ dimension Fig 2.5.6 (d). For the determination of the sugar pucker of each residue, we are interested in the ${ }^{3} \mathrm{~J}_{\mathrm{H} 1}{ }^{\prime} \mathrm{H}^{2}$. The pulse sequence employed is shown in Fig 2.5.6 (c).

Fig 2.5.7 (c) The HCCH E-COSY pulse sequence to elucidate the sugar pucker of nucleic acids

This experiment relies on the initial transfer of magnetization from ${ }^{1} \mathrm{H}$ to ${ }^{13} \mathrm{C}$ using an INEPT step at which point the magnetization can be expressed in the form $2 \mathrm{H}_{\mathrm{z}} \mathrm{C}_{\mathrm{y}}(\mathrm{a})$. This is followed by an evolution period wherein the chemical shift of ${ }^{13} \mathrm{C}$ evolves in the duration $t_{1} / 2+T / 2-\left(T / 2-t_{1} / 2\right)=t_{1}$. The heteronuclear coupling between ${ }^{1} H$ and ${ }^{13} \mathrm{C}$ evolves for $\tau-\mathrm{T} / 2+\tau-\mathrm{t}_{1} / 2+\left(\mathrm{T} / 2-\mathrm{t}_{1} / 2\right)=-\mathrm{t}_{1}+2 \tau$. In the evolution time $\mathrm{t}_{1}$ we get an in phase splitting of the resonances in the $\omega_{1}$ dimension. By adjusting the time interval $2 \tau=1 / 2 \mathrm{~J}_{\mathrm{HC}}$ the evolution of the $\mathrm{J}_{\mathrm{HC}}$ coupling can be described in the operator form

$$
2 \mathrm{H}_{\mathrm{z}} \mathrm{C}_{\mathrm{y}} \rightarrow-\mathrm{C}_{\mathrm{x}}
$$

The homonuclear coupling between 13C spins evolves in time T as described by

$$
-\mathrm{C}_{\mathrm{x}} \rightarrow 2 \mathrm{C}_{1 \mathrm{y}} \mathrm{C}_{2 \mathrm{z}} \sin \left(\pi \mathrm{~J}_{\mathrm{C} 1 \mathrm{C} 2} \mathrm{~T}\right)
$$

At step (b), the $90^{\circ}$ pulse flips the magnetization of ${ }^{13} \mathrm{C}$ to the transverse plane

$$
-2 \mathrm{C}_{1 \mathrm{y}} \mathrm{C}_{2 \mathrm{z}} \rightarrow-2 \mathrm{C}_{1 \mathrm{z}} \mathrm{C}_{2 \mathrm{y}}
$$

When $2 \tau$ is set to $1 / 2 \mathrm{~J}_{\mathrm{HC}}$ the heteronuclear coupling evolves as

$$
2 \mathrm{C}_{1 \mathrm{z}} \mathrm{C}_{2 \mathrm{y}} \rightarrow 4 \mathrm{C}_{1 \mathrm{z}} \mathrm{C}_{2 \mathrm{x}} \mathrm{H}_{2 \mathrm{z}}
$$

And the homonuclear coupling $\mathrm{J}_{\mathrm{CC}}$ under the influence of time $\mathrm{T}_{\mathrm{c}}$

$$
4 \mathrm{C}_{1 \mathrm{z}} \mathrm{C}_{2 \mathrm{x}} \mathrm{H}_{2 \mathrm{z}} \rightarrow 2 \mathrm{C}_{2 \mathrm{y}} \mathrm{H}_{2 \mathrm{z}} \sin \left(\pi \mathrm{~J}_{\mathrm{C} 1 \mathrm{C} 2} \mathrm{~T}_{\mathrm{c}}\right)
$$

$\mathrm{T}_{\mathrm{c}}$ is optimally set to $1 / 4 \mathrm{Jcc}$. The E-COSY element ensures that the $\alpha$ and $\beta$ spin states of ${ }^{1} \mathrm{H}$ after the evolution time $\mathrm{t}_{1}$ don't mix. In a final INEPT step (d), the magnetization is transferred back to ${ }^{1} \mathrm{H}$ and then detected (e).

Fig 2.5.7 (d) The E-COSY splitting pattern allows the unambiguous extraction of ${ }^{3} \mathrm{~J}_{\mathrm{HH}}$ homonuclear coupling along the $\omega_{2}$ dimension and the extraction of the ${ }^{1} \mathrm{~J}_{\mathrm{CH}}$ heteronuclear coupling along the $\omega_{1}$ dimension.

The presence of typical NOEs associated with an A-form helix ( ${ }^{104 ; 105 ; 141 ; 142}$ ) led us to impose 41 non-experimental dihedral angle restraints defining the backbone angles $\alpha, \beta, \varsigma$ and $\varepsilon$, as shown in Fig 2.5.6 (b), within a range of $\pm 60^{\circ}$ for the lower stem residues 16 to 21 and 41 to 46 . Figure 2.5.6 (e) schematically illustrates typical NOEs (exchangeable and non-exchangeable) observable in a stretch of RNA adopting an Aform helix.

Figure 2.5.7 (e) NOEs indicative of A-form helix formation in RNA

### 2.5.8 Planarity and hydrogen bonding

Although X-PLOR NIH provides improper angles to maintain planarity of groups of atoms, the specification of these energy terms is sometimes cumbersome, especially when many atoms are involved. The restraints planarity statement allows one to define an effective energy term that penalizes out-of-plane conformations of the selected atoms. The planarity restraints energy term is defined as

$$
E_{\text {plan }}=\sum_{g \in \text { groups }} \omega_{\text {plan }} \sum_{i \in g} g_{i}^{2}
$$

Where the first sum is carried out over all defined groups of planar atoms, the second sum is carried out for all atoms $i$ within each group, and $g_{i}$ is the orthogonal distance of $i$ from the least-squares plane defined by all atoms of the group.

Hydrogen bonds are of fundamental importance in the formation of RNA structures.
A version of the $2 \mathrm{D}{ }^{15} \mathrm{~N}$ imino-NOESY for observing the exchangeable protons was used to elucidate the presence of hydrogen bonds between Watson Crick base pairs in the TAR RNA. The base pairs were constrained in two ways: 1) NOE style distance restraints between each of the two (for A: U base pairs) or three (for the G: C base pairs) donor-acceptor pairs. 2) A term defining planar pseudo energy terms defined for each base pair.

The failure to observe an imino resonance indicative of hydrogen-bonding scheme between A22 and U40, even at $4^{\circ} \mathrm{C}$ suggested that the A22-U40 hydrogen-bond pattern was sheared. However, several NOEs between U40 to C39/C41, and A22 to G21/G26, which are indicative of residues U40 and A22 remaining stacked between C39/C41 and G21/G26 respectively, lead us to treat the planarity and hydrogen bond restraints between these two restraints with more caution. Hence, while the planarity and hydrogen bond restraints between these two residues were present during the initial high temperature dynamics step of the molecular dynamics protocol to ensure that A22 and U40 remained stacked, these restraints were removed for subsequent stages of the rMD protocol, thus allowing both the residues to sample conformational space in the absence of planarity and hydrogen bond restraints between the two residues but only in the presence of NOE distance restraints indicative of U40 and A22 remaining stacked between C39/C41 and G21/G26 respectively.

### 2.5.9 Structure calculations

Structures were calculated using restrained Molecular Dynamics (rMD) and energy minimization in XPLOR-NIH $\left[{ }^{143 ; 144}\right]$ to obtain the final ensemble of structures of the TAR RNA/AMG complex.
XPLOR-NIH [ ${ }^{[43 ;}{ }^{144}$ ] relies on two files for its knowledge of the molecular structure and energies defined during the restrained Molecular Dynamics run. The topology file defines atom types, bonds, angles and improper terms, while the parameter file contains details regarding force constants for bonds, angles, impropers, dihedrals and non-bonded parameters. It is essential to use the topology and parameter files in tandem because the parameter file uses the information present in the topology file to calculate the molecular structure file (extension .psf).
For the TAR RNA, the latest DNA/RNA Amber [ $\left.{ }^{145}\right]$ parameter and topology files were downloaded from the Moore Lab Homepage (http://proton.chem.yale.edu/).

Since the amino glycoside was a novel structure, not previously studied, the topology and parameter files for AMG were assembled by putting together information from the individual monomer units of N -Acetyl- $\beta$ - d -Glucosaminidase (NAG) and other similar amino sugars and a butadiene monomer unit, available with the distributions of XPLOR-NIH and CNS (Crystallography and NMR System) [ ${ }^{146}$ ].

A starting template and psf file of AMG was created using the customized parameter and topology files.

For the HIV-2 TAR RNA, the RNA coordinates of HIV-2 TAR-Argininamide structure (1AKX.pdb) were used as a starting structure. These two PDB's served as starting templates for subsequent structure calculations using the restrained Molecular Dynamics protocol outlined in the following sections.

In its simplest form, the rMD protocol incorporates distance restraint terms of the form $\mathrm{k}\left(\mathrm{d}-\mathrm{d}_{0}\right)^{2}$ where d is the distance between the atoms in the current conformation and do is the desired distance dynamics approach derived from NMR spectrum. k is a force constant, the value of which determines how tightly the restraint should be applied. The information derived from the 2D HCCH E.COSY experiment on the sugar puckers and the data on other torsion angle restraints can also be incorporated into the molecular dynamics energy function in addition to the distance restraints as derived from the NOE data. The force constants for the NOE and the Dihedral energy terms were set to $50-\mathrm{kcal} / \mathrm{mol} \AA$ and $300-\mathrm{kcal} / \mathrm{mol}{ }^{\circ}$ respectively. Another way to
understand the significance of these force constants is that structures in which the distance between particular atoms or dihedral angles (between planes) exceed the target NOE derived distance or E.COSY derived dihedral angle restraints, then a penalty that is directly proportional to the force constant attributed to these restraints is imposed which contributes to the total energy of the structure. This can be mathematically written as

$$
\begin{array}{lc}
\mathrm{V}(\mathrm{~d})=\mathrm{k}_{\mathrm{l}}\left(\mathrm{~d}-\mathrm{d}_{\mathrm{l}}\right)^{2} & \mathrm{~d}<\mathrm{d}_{1} \\
\mathrm{~V}(\mathrm{~d})=0 & \mathrm{~d}_{1} \leq \mathrm{d} \leq \mathrm{d}_{\mathrm{u}} \\
\mathrm{~V}(\mathrm{~d})=\mathrm{k}_{\mathrm{u}}\left(\mathrm{~d}-\mathrm{d}_{\mathrm{u}}\right)^{2} & \mathrm{~d}_{\mathrm{u}}<\mathrm{d}
\end{array}
$$

Where $d_{1}$ and $d_{u}$ are the lower and upper distances that are consistent with the experimental data. Thus a distance between $d_{1}$ and $d_{u}$ incurs no penalty. Outside this region, the restraint force and the penalty is dictated by the form of the potential function viz. square, harmonic, soft etc. A similar treatment is conferred upon dihedral angles and dipolar coupling restraints (discussed in detail later).

During the simulation, the system develops in a potential field under the influence of various forces, in which all information about the complex is summarized. Two classes of energy terms are distinguished: $\mathrm{E}_{\text {empirical }}$ and $\mathrm{E}_{\text {experimental }}$.

$$
\begin{aligned}
& \mathrm{V}=\mathrm{E}_{\text {empirical }}+\mathrm{E}_{\text {experimental }} \\
& \mathrm{E}_{\text {experimental }}=\mathrm{E}_{\text {NOE }}+\mathrm{E}_{\text {torsion }}+\mathrm{E}_{\text {sani }} \\
& \mathrm{E}_{\text {empirical }}=\mathrm{E}_{\text {bond }}+\mathrm{E}_{\text {angle }}+\mathrm{E}_{\text {dihedral }}+\mathrm{E}_{\mathrm{vdw}}+\mathrm{E}_{\text {electr }}
\end{aligned}
$$

$\mathrm{E}_{\text {empirical }}$ contains all information about the primary structure of the RNA and AMG and also data about topology and bonds in nucleic acids and AMG in general. The contributions of covalent bonds, bond-angles and dihedral angles towards $\mathrm{E}_{\text {empirical }}$ are approximated by a harmonic function. In contrast, non-covalent van-der-Waals forces and electrostatic interactions are simulated by an inharmonic Lennard-Jones potential and Coulomb potential, respectively. Eexperimental takes the experimentally determined constraints into account. Angle constraints are introduced by a harmonic function analogous to that for the dihedral angles. For distance constraints, the energy potential will be set to zero, if the corresponding distance is within the given limits. If it is
outside these limits, a harmonic energy potential is used, which tries to push the value of the distance into the limits.

The restrained Molecular Dynamics protocol consisted of four stages.
The first stage consisted of a preliminary High Temperature Molecular Dynamics run at 1000 K to generate 150 starting templates of the TAR RNA/AMG complex. The use of different seeds for each structure generation leads to different structures. The starting structure (1AKX.pdb, already folded RNA with appropriate base pairing in place) is allowed to undergo high temperature dynamics at 1000 K . Restraints to preserve the A-form helix structure in the lower stem were imposed to maintain helical structure during the high temperature randomization step. The force constants are allowed to increase very slowly (in step factors of 5 till maximum value of the force constants is reached; this can be followed in the XPLOR protocol in the Appendix) thus ensuring that maximum conformational space is sampled during the high temperature dynamics. The goal of a NMR structure calculation is to ensure that the structures generated are defined by the experimental restraints imposed. The total energy and violation energy of NOEs thus provide a tool that can be used to sort structures, which are refining against the restraints to define the structure. The slow increase of the force constants along with the dynamics at high temperature results in structures very different from each other. An r.m.s.d. to the mean of $3.4 \AA$ angstroms (excluding the hexanucleotide loop of the TAR RNA) for an ensemble of chosen structures confirms that the initial high temperature dynamics succeeds in sampling a wide area of conformational space. After the high temperature phase, those structures with total energy less than $600 \mathrm{kcal} / \mathrm{mol}$ and NOE violation energy less than 100 $\mathrm{kcal} / \mathrm{mol}$ were chosen. Only structures meeting the appropriate cut offs in energy values were allowed to pass on to the subsequent stage.

The next stage of the protocol is the Simulated Annealing (SA) wherein structures with reasonable energies generated in the High Temperature phase are subjected to 3 rounds of 3 ps dynamics at $1000 \mathrm{~K}, 600 \mathrm{~K}$ and 400 K with 700 Powell minimization steps between the dynamics [ ${ }^{147}$ ]. All force constants were ramped to their full value and structures were sorted against their total energies and violation energies. The hydrogen-bonding restraints deserve special attention at this stage. The presence of several NOEs between U40 to C39/C41, and A22 to G21/G26 are indicative of residues U40 and A22 remaining stacked between C39/C41 and G21/G26 respectively. However, the failure to observe an imino resonance even at $4^{\circ} \mathrm{C}$ implies
that the hydrogen-bonding scheme between A22 -U40 is disrupted. Consequently, hydrogen-bonding restraints between A22 and U40 were employed only during the high temperature phase of the rMD and were removed for subsequent stages of the protocol. Structures were chosen based on total energy less than $400 \mathrm{kcal} / \mathrm{mol}$ and NOE violation energy less than $50 \mathrm{kcal} / \mathrm{mol}$ after the simulated annealing.

In the refinement protocol that follows the simulated annealing, chosen structures were subjected to 2 ps dynamics at $500,300,150,50$ and 10 K with 1000 steps of Powell minimization between the dynamics. The dihedrals and planarity terms were switched off to allow for sampling all conformational space. At the end of the refinement, structures with NOE violation energy lower than $25 \mathrm{kcal} / \mathrm{mol}$ were chosen for subsequent refinement with the $f$ iRDCs. Structures at this stage had 0 to 4 NOE violations greater than $0.2 \AA$ and no angular violations greater than $5^{\circ}$. The best fourteen structures at this stage converged to $1.6 \AA$ r.m.s.d.

The final stage of calculations consisted of refinement with the incorporation of fiRDCs. While only repulsive Van der Waals non-bonded energy terms were employed in the earlier stages of the protocol to speed up the calculations, at this stage of refinement, the attractive Lennard Jones potential [ ${ }^{143 ;} 144$ ] is switched on. The field induced dipolar couplings were included as restraints for refinement using the "Susceptibility Anisotropy (sani)" algorithm with a square potential well in XplorNIH [ ${ }^{148 ;} 149$. One of the prerequisites to compute the potential arising from "sani" is the presence of external orienting axis which enables the calculation of $\Theta$ and $\Phi$ which are the angles measured between the dipolar vector and the alignment coordinate system, which is represented by four pseudo atoms OO, $\mathrm{X}, \mathrm{Y}$ and Z in Xplor-NIH. OO represents the origin of the coordinate system while $\mathrm{X}, \mathrm{Y}$ and Z represent the Cartesian axis system. The projection of the dipolar vector on the OO-Z axis results in $\cos \Theta$ while the projection onto $\mathrm{OO}-\mathrm{X}$ and $\mathrm{OO}-\mathrm{Y}$ result in $\sin \Theta \cos \boldsymbol{\Phi}$ and $\sin \Theta \sin \boldsymbol{\Phi}$, respectively. The implementation of Susceptibility Anisotropy [ $\left.{ }^{[148 ; 149}\right]$ can be better understood in the following way. The dipolar coupling D arising due to the partial orientation of macromolecules (in our case the TAR RNA / AMG complex) is a function of the relative orientation of the dipolar vectors with respect to the alignment coordinate frame $(\Theta$ and $\Phi)$, the magnitude of the alignment tensor $\left(\mathbf{A}_{\mathbf{a}}\right.$, $\mathbf{A}_{\mathbf{r}}$ or $\mathbf{D}_{\mathrm{a}}, \mathbf{R}$ ), the gyro magnetic ratios of the interacting nuclei $\left(\boldsymbol{\gamma}_{\mathrm{p}}\right.$ and $\left.\boldsymbol{\gamma}_{\mathrm{q}}\right)$, the
distance between the nuclei $\left(\mathbf{r}_{\mathbf{p q}}\right)$ and the generalized order parameter of the dipolar vector (S).

$$
D^{\mathrm{pq}}=-\mathrm{S} \gamma_{\mathrm{p}} \gamma_{\mathrm{p}}\left[\mathrm{~A}_{\mathrm{a}}\left(3 \cos ^{2} \Theta-1\right)+(3 / 2) * \mathrm{~A}_{\mathrm{r}}\left(\sin ^{2} \Theta \cos 2 \Phi\right)\right] / \mathbf{r}_{\mathrm{pq}}^{3}
$$

The above equation reduces to

$$
D^{\mathrm{pq}}=\mathrm{D}^{\mathrm{pq}}{ }_{\text {axial }}\left(3 \cos ^{2} \Theta-1\right)+(3 / 2) * R\left(\sin ^{2} \Theta \cos 2 \Phi\right)
$$

Where $\boldsymbol{\Theta}$ is the angle between the internuclear vector and the $z$-axis of the tensor, and $\boldsymbol{\Phi}$ is the angle between the angle between the projection of the internuclear vector on the $x-y$ plane of the tensor and the $x$-axis.

In Xplor-NIH, the function that is minimized is the difference between the calculated and measured dipolar couplings.

$$
\mathbf{E}_{\text {sani }}=\mathbf{k}\left(\mathbf{D}_{\text {measured }}-\mathbf{D}_{\text {calculated }}\right)^{2}
$$

Where k is the force constant assigned to the "sani" term during the calculation.
To obtain an accurate estimate for $\mathrm{D}_{\mathrm{a}}$ and R , the measured dipolar couplings are plotted as a histogram $\left[{ }^{148}\right]$, the extremes of which correspond to the alignment tensor components $A_{x x}, A_{y y}$, and $A_{z z}$ where $\left|A_{z z}\right| \geq\left|A_{y y}\right| \geq\left|A_{x x}\right|$. Also, the alignment tensor is traceless leading to $\mathrm{A}_{\mathrm{xx}}+\mathrm{A}_{\mathrm{yy}}+\mathrm{A}_{\mathrm{zz}}=0$. Da and R can be computed using the following equations:

$$
\begin{gathered}
A_{z z}=2 A \\
A_{y y}=-D_{a}(1+3 / 2 R) \\
A_{x x}=-D_{a}(1-3 / 2 R)
\end{gathered}
$$

The accuracy of the estimate in the histogram method increases with the increase in the number and types of measured dipolar coupling data. In our case, we rely exclusively on $37{ }^{13} \mathrm{C}^{-1} \mathrm{H}$ field induced dipolar coupling data, which makes the accurate estimation of the magnitude of $\mathrm{D}_{\mathrm{zz}}$ and R difficult via the histogram method. Hence, a grid search $\left[{ }^{149}\right]$ was performed where we evaluated the "sani" energy term as a function of the alignment tensor. A systematic grid search was performed where we sampled the values of $D_{z z}$ between 5 and 10 in 1 Hz steps and values of $R$ between 0.1 and 0.66 in increments of 0.05 . The sani energy term $\left(\mathbf{E}_{\text {sani }}\right)$ associated with each grid value was analyzed and the optimized grid value was chosen such that sani energy term was minimized. The optimized grid value, in conjunction with the experimentally determined error limits (square well potential) was used in the final refinement of the TAR RNA / AMG complex.

Correlation coefficients of the experimentally derived $f$ iRDCs versus the calculated $f i \mathrm{RDCs}$ and the Q factors $\left[{ }^{150}\right.$ ] of the final structures were calculated using DipoCoup [ ${ }^{151}$ ]. Final structures were viewed and analyzed using MOLMOL [ ${ }^{152}$ ].
Scripts written in Awk, Python and Perl languages aided in data conversion, analysis and preparation of input and output scripts.

The general scheme of the calculation and the Xplor scripts used to arrive at the final structures are presented in APPENDIX B. Further, scripts used for the analysis of violations, energies and tensors can be found in APPENDIX C.

## 3 Results

### 3.1 Resonance assignment

The 3D HCCH-COSY-TOCSY experiment was used to get a complete spin assignment of the ribose spin system of the TAR RNA (C1'-H1', C2'-H2', C3'-H3', C4'-H4' and C5'-H5'/H5', correlations). Fig 3.1 (a) and (b) trace the ribose spin connectivity of the U42 and A35 residues of the TAR RNA in the direct dimension (D1 in Felix) respectively. Though the resonances of the $\mathrm{C}^{\prime} /{ }^{\prime} / \mathrm{H} 2^{\prime}$ and $\mathrm{C} 3^{\prime} / \mathrm{H} 3$ ' are overlapped as shown in the figures, the HCCH-COSY-TOCSY experiment allows unambiguous assignment of the ribose spin system. Sequential resonance assignment employing a 3D ${ }^{13} \mathrm{C}$-HSQC NOESY and a base resolved/selective $3 \mathrm{D}{ }^{13} \mathrm{C}$-HSQC NOESY helped correlate the peaks arising from the $\mathrm{H}^{\prime}$ ' or $\mathrm{H} 2^{\prime}$ and the $\mathrm{H} 6 / \mathrm{H} 8$ (i+1) of the TAR RNA nucleotides. The DQF-COSY, TOCSY and NOESY experiments were employed to obtain the resonance assignment of the ligand AMG. Tables 3.1(a, b) summarize the resonance assignment of the TAR RNA and AMG (Fig 3.1(e)) as obtained from the experiments previously described.

Fig 3.1 (a) 2D skewer of the 3D HCCH-COSY-TOCSY experiment in the direct dimension at 4.59 ppm (H2' resonance of the U42) showing the assignment of U42 ribose system.

Fig 3.1 (b) 2D skewer of the 3D HCCH-COSY-TOCSY experiment in the direct dimension at 4.89 ppm (H2' resonance of the A35) showing the assignment of A35 ribose system.

### 3.2 Chemical shift mapping

Chemical shift changes are immediate evidence that binding has occurred. This change is a result from a change in the environment of the nucleotides. A change in line width (or more directly the relaxation rate $1 / T_{1}$ or $1 / T_{2}$ ) may result from a change in the motional characteristics of the RNA $\left[{ }^{5 ; 6}\right]$.

The chemical shift mapping identifies A22, U23 and the loop nucleotides G32, G34 and A35 as the sites being most affected by the binding of the amino glycoside analog AMG. Large chemical shifts changes are observed upon titration of AMG for the $\mathrm{C} 2 / \mathrm{H} 2$ and $\mathrm{C} 1^{\prime} / \mathrm{H} 1$ ' resonances of A 35 . In particular, the line width of the $\mathrm{A} 35-\mathrm{C} 2$ decreases from 80 to 48 Hz at 900 MHz , which suggests that in free TAR RNA, this nucleotide assumes different conformations interchanging on a $\mu \mathrm{s}$ to ms time scale, while in the complex the base occupies a well-defined position. Notable is the chemical shift change experienced by the base of G34, which varies the most upon formation of the complex without showing any direct contact to the ligand. This is indicative of a profound change in the electronic environment of G34 and, possibly, of the overall conformation of the loop, triggered by the interaction of A35 with AMG. The chemical shift change of G34-C8/H8 is accompanied by a considerable decrease in the transverse relaxation time T2 of G34-C8, indicating that G34, which is disordered in the free TAR and in the TAR/argininamide complex [ ${ }^{31 ;} 46 ; 51 ; 153$ ], undergoes a slow ( $\mu \mathrm{s}-\mathrm{ms}$ time scale) conformational transition between two states in complex with AMG [ ${ }^{154}$ ].
Considerable chemical shifts changes are observed also for the ribose of U31, G32 and G33. In the bulge, the largest chemical shift changes are observed for A22 and U23. A medium-sized chemical shift change of G43 C 1 '- H 1 ' resonance suggests additional binding effects in the minor groove of the TAR RNA lower stem.

As shown in Fig 2.5.3, significant chemical shift changes were observed up to a 10fold excess of the ligand AMG over the TAR RNA, indicating that the equilibrium dissociation constant $K_{d}$ is in the micro molar range [ ${ }^{155}$ ]. Further addition of AMG doesn't lead to further changes in the peaks thus leading us to conclude that a stable complex of the HIV-2 TAR RNA with AMG is formed under sample conditions of 10 fold excess of AMG with TAR RNA.

In summary, the most significant chemical shifts changes upon binding of the TAR RNA to AMG are observed either for the base or for the ribose ${ }^{13} \mathrm{C}$ and ${ }^{1} \mathrm{H}$ resonances
of A22, U23, G26, G32, G34 and A35 (rendered in red). Less prominent chemical shift changes are observed for G21, U25, G28, C29, U31, G33, G36 and G43 (rendered in light blue) in Fig 3.2.

Fig 3.2 Chemical shift mapping of TAR-binding sites.

### 3.3 Sugar pucker and dihedral angles

Depending on the J coupling constants between H1' and H2' derived from a 2D-HCCH-E.COSY spectrum, residues of the HIV-2 TAR RNA were classified as being in either C3'-endo or C2'-endo conformation. Table 3.3 summarizes the sugar pucker restraints for the residues of the TAR RNA.

| Residue | Sugar Pucker | Residue | Sugar Pucker |
| :---: | :---: | :---: | :---: |
| $\mathbf{1 6}$ | C3'-endo | $\mathbf{3 2}$ | Unrestrained |
| $\mathbf{1 7}$ | C3'-endo | $\mathbf{3 3}$ | C2'-endo |
| $\mathbf{1 8}$ | C3'-endo | $\mathbf{3 4}$ | Unrestrained |
| $\mathbf{1 9}$ | C3'-endo | $\mathbf{3 5}$ | Unrestrained |
| $\mathbf{2 0}$ | C3'-endo | $\mathbf{3 6}$ | C3'-endo |
| $\mathbf{2 1}$ | C3'-endo | $\mathbf{3 7}$ | C3'-endo |
| $\mathbf{2 2}$ | C3'-endo | $\mathbf{3 8}$ | C3'-endo |
| $\mathbf{2 3}$ | C2'-endo | $\mathbf{3 9}$ | C3'-endo |
| $\mathbf{2 5}$ | Unrestrained | $\mathbf{4 0}$ | C3'-endo |
| $\mathbf{2 6}$ | C3'-endo | $\mathbf{4 1}$ | C3'-endo |
| $\mathbf{2 7}$ | Unrestrained | $\mathbf{4 2}$ | C3'-endo |
| $\mathbf{2 8}$ | C3'-endo | $\mathbf{4 3}$ | C3'-endo |
| $\mathbf{2 9}$ | Unrestrained | $\mathbf{4 4}$ | C3'-endo |
| $\mathbf{3 0}$ | Unrestrained | $\mathbf{4 5}$ | C3'-endo |
| $\mathbf{3 1}$ | Unrestrained | $\mathbf{4 6}$ | C3'-endo |

Table 3.3 Sugar pucker restraints imposed on the residues of the TAR RNA

41 non-experimental dihedral angle restraints defining the backbone angles $\alpha, \beta, \varsigma$ and $\varepsilon$ within a range of $\pm 60^{\circ}$ for the lower stem residues 16 to 21 and 41 to 46 were imposed based on typical NOEs associated with an A-form helix.

### 3.4 Identifying the binding sites of AMG to TAR RNA

The intermolecular NOESY spectrum reveals intimate contacts of AMG with the residues A22, U23, U25 of the bulge and A35 of the loop of the HIV-2 TAR RNA. Table 2.5.6 summarized the intermolecular NOE contacts revealed by the NOESY spectra. This result is in agreement with the chemical shift mapping, which identifies A22, U23, U25 and the loop nucleotides G32, G34 and A35 as the residues being most affected by the binding of AMG to the TAR RNA. The atypical C8/H8 chemical shifts of A35 in the free TAR RNA implies that the adenosine base is partially projected out of the loop, thus occupying an optimal position for interacting with a ligand bound to the bulge on the side of the upper stem major groove. In the bulge, the largest chemical shift changes are observed for A22 and U23. U23 stacks on A22 in the free TAR RNA, while in this complex it is involved in several contacts with AMG. The A22-U40 base pair, which is stably formed at low temperature in the free HIV-2 TAR RNA, is disrupted in the complex, as confirmed by the failure to observe the U 40 imino resonance even at $4^{\circ} \mathrm{C}$. However, several NOEs indicate that both A22 and U40 remain positioned between G21/G26 and C39/C41, respectively.

A35 is the only loop residue that directly contacts the ligand, suggesting that the interaction of AMG with the loop must be part of a more complex network of interactions holding the complex together. Cooperative binding of AMG to both the loop and the bulge of the TAR RNA is supported by the chemical shift data, which indicate a $\mathrm{K}_{\mathrm{d}}$ of comparable magnitude for both the bulge and the loop sites.

Moreover, while AMG inhibits the binding of Tat-derived peptides to the TAR RNA, linear analogues or smaller cyclic analogues of AMG do not show any biological activity $\left[{ }^{91}\right]$, underlining the importance of a cyclic constrained structure of appropriate size for the cooperative binding to the bulge and loop regions of the RNA. Therefore, it is safe to conclude that one molecule of AMG binds simultaneously to the loop and the bulge of the RNA.

A medium-sized chemical shift change of G43-C1' upon titration of AMG, together with NOEs between the aminoglycoside analogue and both G43-H1' and G44-H4', reveal an additional binding site of AMG in the minor groove of the RNA lower stem. This finding is not surprising, as structural studies of the TAR/neomycin B complex [ ${ }^{156}$ ] had identified the lower stem minor groove as a binding site for positively charged aminoglycosides.

### 3.5 Field induced residual dipolar couplings

Under a given high magnetic field $(B)$, the TAR RNA assumes a sufficient level of molecular alignment to allow measurement of $f i \operatorname{RDCs}(\mathrm{D})$ as contributions to normally observed scalar couplings (J+D). The magnitudes of observed fiRDCs depend quadratically on the magnetic field strength $\left(\mathrm{B}^{2}\right)$, and on the principal values of the magnetic susceptibility tensor ( $\chi_{i i} i=\{x, y, z\}$ ). The magnetic susceptibility tensor for the TAR RNA is dominated by the diamagnetic susceptibilities of aromatic base groups $\left(\chi_{i i}{ }^{(\text {base })}\right)$. Corresponding $\chi$-tensors tend to be close to axially symmetric ( $\chi_{y y} \sim \chi_{x x}$ ) with principal values $\left(\chi_{i i}\right)$ that increase approximately linearly with the total number of bases due to constructive addition of base susceptibilities arising due to the fact that stacking interactions favor coplanar arrangement of base planes in nucleic acids.

Comparing experimental $\chi_{i i}$ values determined for an unknown system (in our case the TAR RNA of the TAR/AMG complex) with the corresponding values expected for a monomer TAR RNA can provide new insights into the stoichiometry of the RNA component of the TAR RNA/AMG complex. The principal value of $\chi_{i i}$ for the TAR RNA/AMG system is derived from the values of the fiRDCs. The following points need to be borne in mind when elucidating the $\chi_{\mathrm{ij}}$ in nucleic acids in general.
a) Base interaction vectors are perpendicular to their own principal anisotropy $\left(\chi_{z z}{ }^{\text {(base })}\right)$ and therefore the vector is preferentially positioned within the $\chi_{y y}-$ $\chi_{x x}$ plane of the principal axis system.
b) In nucleic acids, the axially symmetric tensors are very close in value i.e. $\left(\chi_{y y}\right.$ $\sim \chi_{x x}$ ) thus, many RDC values measured for interaction vectors in the $\chi_{y y}-\chi_{x x}$ plane will provide a good estimate for the value of $D_{y y}$.

We also assume that the presence of the AMG in ten-fold excess concentration as the TAR RNA, does not contribute to the alignment of the TAR RNA in the magnetic field.

Fig 3.5. (a) Sensitivity of $f i$ RDC to RNA stoichiometry " $m$ ". Base pairs are shown as dotted lines between colored rectangles in multimers [ ${ }^{134}$ ].

An awk script written in-house ${ }^{*}$ (Appendix C), allowed us to determine the theoretical values arising from a given model and compare this with the experimental value determined for the system.
The experimental values of the field induced residual dipolar couplings and the associated experimental error for each coupling are summarized in Table 3.4. The same values are graphically depicted with error bars in Fig 3.5 (b). These $f i$ RDCs were employed in the final round of refinement during structure calculations of the TAR RNA/AMG complex.
A few dipolar couplings of the base $\mathrm{C}-\mathrm{H}$ atom pairs measured at 800 MHz assume values between 5 and 7 Hz . These figures exceed by far those expected for the TAR RNA aligned in the magnetic field due to the magnetic susceptibility anisotropy of the bases [ $\left.{ }^{135}\right]$. The largest dipolar coupling tensor is expected for coaxial stacking of the upper and lower stems and would correspond to a $D_{z z}$ of 8 Hz and a rhombicity $R$ between 0 and 0.1 in an 800 MHz field. For such a tensor, the largest base $\mathrm{C}-\mathrm{H}$ dipolar coupling should not exceed 4 Hz . The high values found for the TAR RNA/AMG complex suggest that the TAR RNA dimerizes in the presence of the ligand AMG. This conclusion is also in agreement with the $T_{1}$ relaxation measurements.

Fig 3.5. (b) Bar graph with errors showing the distribution of field induced Residual Dipolar Couplings in various residues of the TAR RNA in the TAR/AMG complex

### 3.6 NOE distance restraints

A total of 127 internucleotide and 320 intranucleotide distance restraints were extracted from a 3D ${ }^{13} \mathrm{C}$-HSQC NOESY (mixing time 100 ms ) and a base resolved/selective 3D ${ }^{13} \mathrm{C}$-HSQC NOESY (mixing time 100 ms ).

As described in the Materials and Methods section (Fig 2.5.5 (b)), an iterative assignment process for the intermolecular NOEs was adopted. The r.m.s.d of the upper stem-binding site, formed by AMG and the TAR RNA residues A22, U23, U25 and A35, and the r.m.s.d of the whole complex, excluding the loop residues C30 to A35, were evaluated for 20 energetically most favorable structures in all the cases discussed. These results are summarized in Table 3.6.

| Run | R.M.S.D $(\AA)$ |  |
| :---: | :---: | :---: |
| $\mathbf{1}$ | Core | All $^{*}$ |
| $\mathbf{2}$ | 3.17 | 2.01 |
| $\mathbf{3}$ | 3.63 | 2.31 |
| $\mathbf{4}$ | 3.04 | 2.00 |
| $\mathbf{5}$ | 3.66 | 2.44 |
| $\mathbf{6}$ | 2.99 | 1.91 |
| $\mathbf{7}$ | 3.55 | 2.45 |
|  | 2.54 | 1.85 |

Table 3.6 r.m.s.d values of different intermolecular NOE schemes considered in Fig 2.5.5 (b)

The upper stem binding site of the complex converged best for the seventh set of intermolecular NOEs. The average r.m.s.d value for the remaining calculations was $\approx$ 3 angstroms for the upper stem binding core and $\approx 2.25 \AA$ for the whole complex excluding the loop, while in the favored seventh set, the average r.m.s.d value $\approx 2.5 \AA$ for the upper stem binding core and $\approx 1.85 \AA$ for the whole complex excluding the loop. An iterative assignment process further released some of the ambiguities in the seventh intermolecular NOEs data set during structure calculation to improve the convergence profile ( $\approx 2.15 \AA$ for the upper stem binding core and $\approx 1.75 \AA$ for the whole complex excluding the loop). A total of 55 intermolecular distance restraints were obtained from a ${ }^{13} \mathrm{C}$-edited $/{ }^{12} \mathrm{C}$-filtered HSQC-NOESY spectrum acquired in $\mathrm{D}_{2} \mathrm{O}$ with a mixing time of 200 ms .

### 3.7 Structure calculations

The restraints used to arrive at the final structures are summarized in Table 3.7.
The XPLOR protocols (Appendix) were used to arrive at the ensemble of final structures of the TAR RNA/AMG complex. The fourteen best structures (energetically favorable), after the refinement with fiRDCs are superimposed in Figure 3.7 (a). The effect of the $f i$ RDCs on the structures can be better appreciated by comparing the structures before and after the refinement (Figure 3.7 (b)).

Figure 3.7 (a) The best-fit superposition to the average structure of the 14 best structures of all the residues except the hexanucleotide loop. The AMG is in red and the TAR RNA is colored black. Notice that the upper stem is not coaxially stacked atop the lower stem as it does in the TAR/argininamide structure.

Fig. Results of refinement using field induced dipolar couplings of the RNA on the global and local structure of the TAR RNA - amino glycoside complex. A comparison of the induced dipolar couplings (right) shows a clear improvement in the global structure of the ensemble in spite of local structures being defined precisely only by employing distance and dihedral restraints (a). For clarity, the residues of the ligand, bulge and disordered loop have been omitted. Only heavy atoms of the terminal base pairs (residues 16 and 46 ) were superimposed to highlight the significance of RDC data in addition to classical NMR restraints for defining the global bend. In $b, c$, $d$ and e an attempt has
been made to compare the precision of base - pair residues in the upper stem of the TAR RNA ( $29-36,28-37,27-38,26-39$ respectively) upon the use of $f$ iRDCs. It is clear that RDCs also help in improving the local precision in addition to determining the global fold of the RNA.

### 3.8 The upper stem binding site

The structure calculation employing NOEs and dihedral angle restraints, conducted on a monomeric unit containing one TAR and one ligand molecule binding to the upper stem, resulted in a well-defined structure in both stems but in a poor definition of the relative orientation of the two stems [root mean square deviation (r.m.s.d.) for the lower stem, 0.5 ; r.m.s.d. for the upper stem, 0.8$]$. The structure refinement with the $\mathrm{C}-\mathrm{H} f i \mathrm{RDCs}$ positioned the two stems at a relative angle of $60^{\circ}$. The 14 lowest-energy structures of the monomeric unit are shown in Figure 3.7 (a). The RNA is well defined with a total heavy atom r.m.s.d. (excluding the loop residues) of 0.92 . The Aform helix structure of the lower (nucleotide 16-21, 41-46) and upper (nucleotide 26-$29,36-39)$ stems is conserved. The upper stem helix is, however, slightly distorted, with the $\alpha$ and $\gamma$ angles varying from the typical A-form gauche - and gauche + conformations to the trans conformation for residues A27-C29 and C39. AMG binds to the bulge and the loop residues on the major groove side of the upper stem. Owing to the 4 -fold symmetry of its resonances and the fast kinetics of complex dissociation, the structure of AMG in the complex cannot be determined. However, the salient features of the interaction between the aminoglycoside analogue and the TAR RNA are well defined and the r.m.s.d. of the whole complex excluding the loop residues $30-34$ is $1.2 \AA$. The backbone of the $22-25$ stretch opens up to allow AMG to reach the major groove of the RNA upper stem. The last base pair of the lower stem is disrupted: U40 stacks below C39; A22 stacks below G26 but tilts away from U40 to widen the major groove of the upper stem and make place for the ligand. Thus, in the TAR/AMG complex, A22 and U40 belong to the upper stem, while in free TAR they stack on the top of the lower stem G21-C41 base pair. The planarity of the G26-C39 base pair is slightly distorted, as indicated by the weakening of the G26 imino resonance upon complex formation. The $\pi$-orbital of the U23 and U25 bases entertain hydrophobic interaction with linker-4 and sugar-3/linker-2 of AMG, respectively. Such hydrophobic contacts resemble a well-known interaction motif in complexes of proteins with oligosaccharides, where the sugars often stack below aromatic side chains [ ${ }^{157}$ ].

The conformation induced by AMG at the bulge site of the TAR RNA, as well as the relative orientation of the two stems, differ from those found in the Tat/TAR complex.

Binding of AMG does not induce either the formation of the U23-A27-U38 base triple or the subsequent coaxial stacking of the upper and lower stems, as it is the case for the binding of the Tat mimetic argininamide [22;82;158;159]. Instead, the bulge nucleotides are all exposed to the solvent in the TAR RNA/AMG complex and the axes of the two stems form an angle of $60^{\circ}$. The relative position of the two domains is probably a consequence of the disruption of the A22-U40 base pair, of the tilting of A22 to accommodate the large ligand and of the electrostatic interactions of the ligand amino group with the phosphate of A22. A35 stacks on the top of the sugar-1 moiety of the ligand and is involved in a $\pi$-cation interaction with the positively charged amino group. This contact pulls A35 out of the loop, causing G34 to move on the top of G36 in all structures.

In $60 \%$ of the structures G34 stacks on the top of G36, while in the other $40 \%$ the two bases interact face-to-edge. The presence of an equilibrium between two conformations is compatible with the large line width of the G34-C8 resonance, suggesting that the exchange between the face-to-face and face-to-edge orientations of G34 and G36 occurs on an $\mu \mathrm{s}-\mathrm{ms}$ time scale [ ${ }^{154 ; 160}$ ].
The positively charged amino groups of the four sugars of AMG interact with various functional groups of the RNA. The amino group of sugar-1 is involved, as already mentioned, in a $\pi$-cation interaction with A35 and in long-range electrostatic interactions with the O 2 of U 25 . The amino group of sugar- 3 is directed towards the major groove carbonyls of the A27-U38 and G28-C39 base pairs in all structures but two, while the amino group of sugar-5 is close to the phosphate backbone of A22 and/or to the O4 of U23. Finally, no consistent contact is found for the amino group of sugar-7. These results are in agreement with the failure to detect H -bonding of the amino groups of AMG to the phosphate backbone of the RNA by the $\mathrm{J}_{\mathrm{NP}}$ scalar coupling measurement, as most of the amino groups of the ligand contact base functional groups rather than backbone phosphates of the RNA.

### 3.9 Definition of the second binding site and of the dimer geometry

Similar to neomycin $\left[{ }^{156}\right]$, the AMG binds also to the minor groove of the lower stem of the TAR RNA. The chemical shift change of G43-C1' is maximum at a $1: 1$ ratio of TAR RNA: AMG, as opposed to the chemical shift changes in the bulge and loop region, which increase up to a $1: 10$ ratio. Thus, the binding constant of AMG to the minor groove of the TAR RNA is higher than that to the bulge and loop regions. This finding is confirmed by the analysis of the PACE data (discussed later). Field induced Residual Dipolar Couplings and relaxation data suggest that TAR RNA dimerizes during the complex formation.
The presence of only one set of resonances in the complex and the absence of NOEs between two TAR RNA moieties further suggests that the dimer is symmetric and that the TAR RNA dimerizes via the presence of one or more AMG molecules between the two dimerizing TAR RNAs.

Figure 3.9 (i) Schematic representations of the association of TAR RNA with the aminoglycoside analogue AMG and of dimer formation.

The $f i \mathrm{RDC}$ data suggests association of two TAR/AMG units with two stems of the two RNA molecules in a roughly parallel orientation and the other two stems diverging from each other. Further, the data is compatible with a dimer structure where lower stems are parallel to each other and upper stems diverge at an angle of about $60^{\circ}$. This geometry is compatible with the tensor derived from the systematic grid search which revealed a minimum at $\mathrm{D}_{\mathrm{zz}}=7 \mathrm{~Hz}$ and $\mathrm{R}=0.55$. The alignment tensor of the given model can be back calculated using the awk script provided in

APPENDIX C. These constraints on the dimer can be satisfied in four different scenarios each of them depicted in Figure 3.9 (i). In the first case (a), three molecules of AMG bind to the loop, the bulge and lower stem of the TAR RNA and the RNA dimerizes with the two upper stems parallel to each other. Case (b) considers two molecules of AMG binding to the loop and the bulge of the TAR RNA and the RNA dimerizes with the two lower stems roughly parallel to each other with one molecule of AMG intervening between the two dimerizing RNAs thus giving rise to complex formation with 2 TAR RNAs and 5 molecules of AMG. In case (c), one molecule of AMG binds to the upper stem major groove simultaneously contacting both the bulge and the loop of the TAR RNA, while a second molecule of AMG binds to the lower stem minor groove and the RNA dimerizes with the two upper stems parallel to each other. The final case (d) considers the binding of one molecule of AMG to the upper stem major groove simultaneously contacting the bulge and the loop of each of the TAR RNAs, while the second molecule of AMG contacts the lower stem minor groove of the TAR RNA. The RNA dimerizes with the two lower stems oriented roughly parallel to each other with one molecule of AMG between the parallel lower stem minor grooves of the RNAs (2 TAR RNAs: 3 AMG). Structure calculations of all the four cases investigated, resulted in very high energy structures due to the distortion of AMG in the dimer complex in case (a) and (c). Only case (b) and (d) were found to be consistent with the observed intermolecular NOEs and did not result in distortion of AMG and high-energy structures. However, case (b), which includes 5 molecules of AMG binding to two molecules of TAR RNA can be excluded based on the following reasons:
(i) Residue A35 is the only nucleotide of the hexanucleotide loop showing intermolecular NOEs to AMG indicating that the binding of AMG to this residue must be a part of a more complex network of interactions
(ii) Chemical shift data indicate that AMG binds to the bulge and the loop of the RNA with the same $\mathrm{K}_{\mathrm{d}}$, suggesting cooperative binding to both the upper stem binding site and the lower stem binding site.
(iii) Smaller cyclic analogues or linear analogues of AMG do not show any detectable binding to the TAR RNA [ ${ }^{91}$ ], emphasizing on the relevance of cooperative binding to multiple sites.
(iv) Entropic contribution strongly disfavors case (b) with respect to case (d).

Thus, case (b) was excluded from further consideration and case (d) was identified as
the preferred model for dimer formation through the aminoglycoside bound to the lower stem minor groove as the only one consistent with the NOE data.

To arrive at an ensemble of dimers that is compatible with our interpretation of the residual dipolar coupling data, relaxation and biochemical results i.e. a dimer model where the TAR RNA undergoes dimerization through one molecule of AMG bridging the lower stems of two molecules of TAR RNA, the following approach was adopted. The monomer entity (TAR/AMG complex) was predisposed by rigid body dynamics (see protocol in APPENDIX for details) in an orientation that was compatible with all the experimental data (case $\mathbf{d}$ as described above). Then, a third molecule of AMG was docked to the minor groove of the two TAR/AMG molecules, guided by NOE restraints of AMG to G43-H1' and G44-H4'. The docking was performed by MD simulations in explicit water solvent [ ${ }^{161}$ ]. A brief description of the MD simulation is summarized below: Simulations were performed with X-PLOR [ ${ }^{[43 ;} 144$ ] by using the same force fields for the RNA and AMG as described above with an electrostatic cutoff of $12 \AA$. The complex is surrounded by a layer of TIP3 water molecules [ ${ }^{[162}$ ], and the solvent is briefly equilibrated. Before the dynamics began, the system was equilibrated by 500 steps of Powell minimization of only the protons of the complex while the heavy atoms are kept fixed, another 100 steps of minimization to equilibrate the water molecules while the complex is kept fixed, 500 steps of minimization while the complex is harmonically restrained and finally 500 steps of free minimization of the TAR/AMG in water. This ensured that the TAR RNA/AMG complex was well equilibrated in the water layer (solvent) generated by TIP3 protocol. The MD protocol consisted of an initial heating stage ( 200 steps at $100 \mathrm{~K}, 200 \mathrm{~K}, 300 \mathrm{~K}, 500 \mathrm{~K}$ and 600 K with a time step of 0.002 ps ) followed by refinement at 600 K ( 2000 steps, 0.003 ps ). Finally, the system was cooled from 600 K to 25 K with the temperature decreasing in steps of 25 K ( 200 steps, 0.003 ps at each step). The MD protocol ended with 200 steps of Powell minimization.

Figure 3.9 (ii) Ensemble of 10 structures of the dimer of HIV-2 TAR RNA (black) in conjunction with 3 molecules of AMG (red). The heavy atoms of residues 16 to 29,36 to 46 and AMG have been superimposed. The bulge and loop residues of the TAR are shown in grey.

The ensemble of models shown in Figure 3.9 (ii) are compatible with all experimental data, including NOEs, relaxation rates, $f i$ RDCs and PACE gel electrophoresis. In this model, the aminoglycoside analogue AMG binds almost symmetrically to the minor groove of the lower stems of the two TAR RNA units. One amino group enjoys electrostatic interactions with the negative spot created by the phosphate groups of G21, A22 and U23, while another amino group closely contacts the 2'-hydroxyl of C45. Two sugars and the intervening linker of AMG penetrate the minor groove of each RNA molecule at the G43-C45 site.

### 3.10 RNase digestion and PACE gel analysis

In agreement with the identification of A22, U23, U25 in the bulge and G32, G34 and A35 as the sites being most affected by the binding of AMG to TAR RNA by Chemical Shift mapping, digestion with RNase T1 and with RNase A suggests that loop residues G32 to G34 and residue C30 respectively, are protected by the binding of AMG to TAR RNA. The RNase foot printing analysis can be followed on Figure 3.10(a). These protection assays of the TAR RNA / AMG complex were carried out with $10 \mu \mathrm{M} 5,{ }^{32} \mathrm{P}$-labeled HIV-2 TAR RNA at 277 K . The digestion experiments were analyzed by gel electrophoresis.

As is evident from the digestion experiments, the ligand AMG protects residues G32, G34 and C30 from digestion by the RNase. This is in agreement with the chemical shift mapping, which identifies G32, G34 and A35 as the sites being most affected by the binding of AMG to the TAR RNA.

Figure 3.10 (a) RNase footprinting shows digestion with (A) RNase A (selective for CYT and URI residues). Lane 1, control without RNase, Lane 2, AMG ( 10 mM ); Lane 3, AMG ( 5 mM ); Lane 4, AMG $(500 \mu \mathrm{M})$; Lane 5, AMG ( $1.2 \mu \mathrm{M}$ ); Lane 6, AMG ( $0.12 \mu \mathrm{M}$ ). (B) Digestion with RNase T1 (selective for GUA residues). Lane 1, control without RNase; Lane2, AMG (10 mM); Lane 3, AMG (5 $\mathrm{mM})$; Lane 4, AMG $(500 \mu \mathrm{M})$; Lane 5, AMG $(1.2 \mu \mathrm{M})$; Lane 6, AMG $(0.12 \mu \mathrm{M})$.

The PACE gel analysis allowed us to test different binding models of the TAR RNA and AMG. We considered a total of 6 different models as described in the Methods (Section 2.4). The retardation distance of the TAR RNA binding to AMG at various concentrations ( $0,2,5,7,10,20,70,100,200$ and $500 \mu \mathrm{M}$ ) can be elucidated from the autoradiogram as shown in Figure 3.10(b).
Lane A
B
C
D
E
F
G

Figure 3.10 (b) Autoradiogram of $5,{ }^{32}$ P labeled HIV-2 TAR RNA binding to different concentrations of AMG. Lane A depicts unbound RNA while lanes B, C, D, E, F and G show TAR RNA in the presence of $500,200,100,70,20$ and $10 \mu \mathrm{M}$ AMG respectively. The bars enable us to elucidate the retardation distance in each lane, data that is subsequently used for the calculation of binding stoichiometry.

The experimentally determined fraction of the RNA bound $(\phi)$ are summarized in Table 3.10.

| Concentration [AMG] | $\phi$ |
| :---: | :---: |
| $500 \mu \mathrm{M}$ | 1.00 |
| $200 \mu \mathrm{M}$ | 0.96 |
| $100 \mu \mathrm{M}$ | 0.73 |
| $70 \mu \mathrm{M}$ | 0.63 |
| $20 \mu \mathrm{M}$ | 0.36 |
| $10 \mu \mathrm{M}$ | 0.20 |
| $7 \mu \mathrm{M}$ | 0.18 |
| $2 \mu \mathrm{M}$ | 0.08 |
| $0 \mu \mathrm{M}$ | 0.00 |

Table 3.10 Experimental values of $\phi$ as measured from PACE gel.

The six theoretical binding models can be analyzed as follows:
For the sake of convenience, the following conventions were adopted.
The AMG concentration was designated as [A], the TAR RNA concentration is [T]. $\left[\mathrm{C}_{1}\right]$ and $\left[\mathrm{C}_{2}\right]$ are the concentrations of the complexes formed, $\mathrm{K}_{\mathrm{d} 1}$ and $\mathrm{K}_{\mathrm{d} 2}$ are the constants.

Case (i)
One molecule of the TAR RNA binds to one molecule of AMG.

$$
\begin{gathered}
\mathrm{T}+\mathrm{A} \xlongequal{\mathrm{~K}_{\mathrm{d}}} \mathrm{C}_{1} \\
\text { Where } \mathrm{K}_{\mathrm{d}}=[\mathrm{T}][\mathrm{A}] /\left[\mathrm{C}_{1}\right] \\
\text { Rearranging, we have }\left[\mathrm{C}_{1}\right]=[\mathrm{T}][\mathrm{A}] / \mathrm{K}_{\mathrm{d}} \ldots \text { (a) }
\end{gathered}
$$

The fraction of bound RNA
$\phi=$ Concentration of complex/Total concentration of RNA= $\left[\mathrm{C}_{1}\right] /\left\{[\mathrm{T}]+\left[\mathrm{C}_{1}\right]\right\}$
Substituting for $\left[\mathrm{C}_{1}\right]$ from (a) we obtain

$$
\phi=[\mathrm{A}] /\left\{\mathrm{K}_{\mathrm{d}}+[\mathrm{A}]\right\} \ldots \text { Equation } 1
$$

Case (ii)
One molecule of the TAR RNA binds to two molecules of AMG

$$
\begin{gathered}
\mathrm{T}+2 \mathrm{~A} \xlongequal{\mathrm{~K}_{\mathrm{d}}} \mathrm{C}_{1} \\
\text { Where } \mathrm{K}_{\mathrm{d}}=[\mathrm{T}][\mathrm{A}]^{2} /\left[\mathrm{C}_{1}\right] \\
\text { Rearranging, we have }\left[\mathrm{C}_{1}\right]=[\mathrm{T}][\mathrm{A}]^{2} / \mathrm{K}_{\mathrm{d}} \ldots(\mathrm{~b})
\end{gathered}
$$

The fraction of bound RNA
$\phi=$ Concentration of complex/Total concentration of RNA $=\left[\mathrm{C}_{1}\right] /\left\{[\mathrm{T}]+\left[\mathrm{C}_{1}\right]\right\}$
Substituting for $\left[\mathrm{C}_{1}\right]$ from (b) we obtain

$$
\phi=[\mathrm{A}]^{2} /\left\{\mathrm{K}_{\mathrm{d}}+[\mathrm{A}]^{2}\right\} \ldots \text { Equation } 2
$$

## Case (iii)

Two molecules of the TAR RNA binds to one molecule of AMG

$$
\begin{gathered}
2 \mathrm{~T}+\mathrm{A} \xlongequal[\mathrm{~A}]{\mathrm{K}_{\mathrm{d}}} \mathrm{C}_{1} \\
\text { Where } \mathrm{K}_{\mathrm{d}}=[\mathrm{T}]^{2}[\mathrm{~A}] /\left[\mathrm{C}_{1}\right] \\
\text { Rearranging, we have }\left[\mathrm{C}_{1}\right]=[\mathrm{T}]^{2}[\mathrm{~A}] / \mathrm{K}_{\mathrm{d}} \ldots(\mathrm{c} 1)
\end{gathered}
$$

The total concentration of RNA (C) is given by $[\mathrm{C}]=2\left[\mathrm{C}_{1}\right]+[\mathrm{T}] \ldots$ (c2)
Keeping in mind that each $\left[\mathrm{C}_{1}\right]$ contributes 2 TAR moieties.
Combining (c1) and (c2), we obtain a quadratic equation as follows:

$$
\left\{2[\mathrm{~T}]^{2}[\mathrm{~A}] / \mathrm{K}_{\mathrm{d}}\right\}+[\mathrm{T}]-[\mathrm{C}]=0
$$

which can be solved for [T]. One of the two solutions can be discarded, as concentration cannot be negative, thus leading to

$$
\begin{equation*}
[\mathrm{T}]=\left(-\mathrm{K}_{\mathrm{d}}+\operatorname{sqrt}\left(\mathrm{K}_{\mathrm{d}}^{2}+8[\mathrm{C}][\mathrm{A}] \mathrm{K}_{\mathrm{d}}\right)\right) / 4[\mathrm{~A}] . \tag{c3}
\end{equation*}
$$

The equation for the fraction of bound RNA $(\phi)$ can be arrived at using the above equations and the final equation after simplification yields:

$$
\begin{array}{r}
\phi=\left(4[\mathrm{C}][\mathrm{A}]+\mathrm{K}_{\mathrm{d}}-\operatorname{sqrt}\left(\mathrm{K}_{\mathrm{d}}^{2}+8[\mathrm{C}][\mathrm{A}] \mathrm{K}_{\mathrm{d}}\right)\right) /\left(4[\mathrm{C}][\mathrm{A}]-\mathrm{K}_{\mathrm{d}}+\operatorname{sqrt}\left(\mathrm{K}_{\mathrm{d}}^{2}+8[\mathrm{C}][\mathrm{A}] \mathrm{K}_{\mathrm{d}}\right)\right) \\
\ldots \text { Equation } 3 \\
\hline
\end{array}
$$

## Case (iv)

One molecule of the TAR RNA binds to two molecules of AMG with different $K_{d}$

$$
\begin{aligned}
& \mathrm{T}+\mathrm{A} \stackrel{\mathrm{~K}_{\mathrm{d} 1}}{\rightleftharpoons} \mathrm{C}_{1} \\
& \mathrm{C}_{1}+\mathrm{A} \stackrel{\mathrm{~K}_{\mathrm{d} 2}}{\rightleftharpoons} \mathrm{C}_{2}
\end{aligned}
$$

Where $\mathrm{K}_{\mathrm{d} 1}=[\mathrm{A}][\mathrm{T}] /\left[\mathrm{C}_{1}\right]$
Rearranging, we have $\left[\mathrm{C}_{1}\right]=[\mathrm{T}][\mathrm{A}] / \mathrm{K}_{\mathrm{d} 1} \ldots(\mathrm{~d} 1)$
Where $\mathrm{K}_{\mathrm{d} 2}=[\mathrm{A}]\left[\mathrm{C}_{1}\right] /\left[\mathrm{C}_{2}\right]$
Substituting for $\left[\mathrm{C}_{1}\right]$ from (d1) and rearranging, we have

$$
\left[\mathrm{C}_{2}\right]=[\mathrm{T}][\mathrm{A}]^{2} / \mathrm{K}_{\mathrm{d} 1} \mathrm{~K}_{\mathrm{d} 2} \ldots(\mathrm{~d} 2)
$$

Further, it has to be borne in mind that the total distance migrated of the bound form of the RNA is a combination of the distance migrated by $\mathrm{C}_{1}$ and $\mathrm{C}_{2}$. Though the individual distances migrated by the two complexes cannot be determined accurately,
it is safe to say that bound distance of $\mathrm{C}_{1}$ is less than the bound distance $\mathrm{C}_{2}$ and a factor Z (value between 0 and 1) can be introduced that is defined as $Z=\frac{D_{C 1}-D_{F}}{D_{C 2}-D_{F}}$ where $\mathrm{D}_{\mathrm{C} 1}$ and $\mathrm{D}_{\mathrm{C} 2}$ are the distance traveled by the complexes C 1 and C 2 respectively and $D_{F}$ is the distance traveled by the free TAR RNA. The value of $Z$ is defined within the boundary condition of 0 and 1 during the curve fitting/ optimization procedure.

The fraction of bound RNA $\phi$ is given by

$$
\phi=\left\{[\mathrm{A}]^{2}+[\mathrm{A}] \mathrm{Z} \mathrm{~K}_{\mathrm{d} 2}\right\} /\left\{\mathrm{K}_{\mathrm{d} 1} \mathrm{~K}_{\mathrm{d} 2}+\mathrm{K}_{\mathrm{d} 2}[\mathrm{~A}]+[\mathrm{A}]^{2}\right\} \ldots \text { Equation } 4
$$

Case (v)
One molecule of the TAR RNA binds one molecule of AMG to give complex $\mathrm{C}_{1}$ with constant $\mathrm{K}_{\mathrm{d} 1}$. Subsequently $\mathrm{C}_{1}$ dimerizes to give $\mathrm{C}_{2}$ with constant $\mathrm{K}_{\mathrm{d} 2}$.

$$
\mathrm{T}+\mathrm{A} \stackrel{\mathrm{~K}_{\mathrm{d} 1}}{\rightleftharpoons} \mathrm{C}_{1}
$$

$$
2 \mathrm{C}_{1} \stackrel{\mathrm{~K}_{\mathrm{d} 2}}{\rightleftharpoons} \mathrm{C}_{2}
$$

Where $\mathrm{K}_{\mathrm{d} 1}=[\mathrm{A}][\mathrm{T}] /\left[\mathrm{C}_{1}\right]$
Rearranging, we have $\left[\mathrm{C}_{1}\right]=[\mathrm{T}][\mathrm{A}] / \mathrm{K}_{\mathrm{d} 1} \ldots(\mathrm{e} 1)$
Where $\mathrm{K}_{\mathrm{d} 2}=\left[\mathrm{C}_{1}\right]^{2} /\left[\mathrm{C}_{2}\right]$
Substituting for $\left[\mathrm{C}_{1}\right]$ from (e1) and rearranging, we have $\left[\mathrm{C}_{2}\right]=[\mathrm{T}]^{2}[\mathrm{~A}]^{2} / \mathrm{K}_{\mathrm{d} 1}{ }^{2} \mathrm{~K}_{\mathrm{d} 2}$

The total concentration of RNA (C) is given by $[\mathrm{C}]=[\mathrm{T}]+\left[\mathrm{C}_{1}\right]+2\left[\mathrm{C}_{2}\right]$ keeping in mind that each [ $\mathrm{C}_{2}$ ] contributes 2 TAR RNA moieties.

Also, like in case (iv), we define a constant Z, that takes into account the differential migration rates of $\mathrm{C}_{1}$ and $\mathrm{C}_{2}$.
The equation for the fraction of bound RNA ( $\phi$ ) can be arrived at using the above results and the final equation after simplification yields:

$$
\begin{aligned}
& \phi=\left(\left(\mathrm{K}_{\mathrm{d} 2} *\left(\mathrm{~K}_{\mathrm{d} 1}+[\mathrm{A}]\right)^{\wedge} 2+4 * \mathrm{C}^{*}[\mathrm{~A}]^{\wedge} 2-\left(\mathrm{K}_{\mathrm{d} 1}+[\mathrm{A}]\right)^{*} \mathrm{sqrt}\left(\mathrm{~K}_{\mathrm{d} 2}{ }^{\wedge} 2 *\left(\mathrm{~K}_{\mathrm{d} 1}+[\mathrm{A}]\right)^{\wedge} 2+8^{*} \mathrm{C}^{*}\right.\right.\right. \\
& \left.\left.\mathrm{K}_{\mathrm{d} 2} *[\mathrm{~A}]^{\wedge} 2\right)\right)^{2}\left(\mathrm{Z}^{*} 2^{*}[\mathrm{~A}]^{*} \operatorname{sqrt}\left(\mathrm{~K}_{\mathrm{d} 2}{ }^{\wedge} 2^{*}\left(\mathrm{~K}_{\mathrm{d} 1}+[\mathrm{A}]\right)^{\wedge} 2+8 * \mathrm{C}^{*} \mathrm{~K}_{\mathrm{d} 2} *[\mathrm{~A}]^{\wedge} 2\right)-\left(\mathrm{K}_{\mathrm{d} 1}+[\mathrm{A}]\right) * 2 *\right. \\
& \left.\left.\mathrm{K}_{\mathrm{d} 2} *[\mathrm{~A}]\right)\right) /\left(\left([\mathrm{A}]+\mathrm{K}_{\mathrm{d} 1}\right) * \mathrm{sqrt}\left(\mathrm{~K}_{\mathrm{d} 2}{ }^{\wedge} 2 *\left(\mathrm{~K}_{\mathrm{d} 1}+[\mathrm{A}]\right)^{\wedge} 2+8^{*} \mathrm{C}^{*} \mathrm{~K}_{\mathrm{d} 2} *[\mathrm{~A}]^{\wedge} 2\right)-\mathrm{K}_{\mathrm{d} 2} *([\mathrm{~A}]+\right. \\
& \left.\mathrm{K}_{\mathrm{d} 1}\right)^{\wedge} 2+4 * \mathrm{C}^{*}[\mathrm{~A}]^{\wedge} 2 \text { ) ...Equation } 5
\end{aligned}
$$

Case (vi)
Two molecules of the TAR RNA bind one molecule of AMG to give complex $\mathrm{C}_{1}$ with constant $K_{d 1}$. Subsequently $C_{1}$ recruits two molecules of AMG to give $C_{2}$ with a constant $\mathrm{K}_{\mathrm{d} 2} . \mathrm{C}_{2}$ is a complex of 2 TAR RNA molecules and three AMG.

$$
\begin{gathered}
2 \mathrm{~T}+\mathrm{A} \xlongequal{\mathrm{~K}_{\mathrm{d} 1}} \mathrm{C}_{1} \\
\mathrm{C}_{1}+2 \mathrm{~A} \xlongequal{\mathrm{~K}_{\mathrm{d} 2}} \mathrm{C}_{2} \\
\text { Where } \mathrm{K}_{\mathrm{d} 1}=[\mathrm{A}][\mathrm{T}]^{2} /\left[\mathrm{C}_{1}\right] \\
\text { Rearranging, we have }\left[\mathrm{C}_{1}\right]=[\mathrm{T}]^{2}[\mathrm{~A}] / \mathrm{K}_{\mathrm{d} 1} \ldots(\mathrm{fl}) \\
\text { Where } \mathrm{K}_{\mathrm{d} 2}=\left[\mathrm{C}_{1}\right][\mathrm{A}]^{2} /\left[\mathrm{C}_{2}\right]
\end{gathered}
$$

Substituting for $\left[\mathrm{C}_{1}\right]$ from (f1) and rearranging, we have $\left[\mathrm{C}_{2}\right]=[\mathrm{T}]^{2}[\mathrm{~A}]^{3} / \mathrm{K}_{\mathrm{d} 1} \mathrm{~K}_{\mathrm{d} 2}$

The total concentration of RNA (C) is given by $[\mathrm{C}]=[\mathrm{T}]+2\left[\mathrm{C}_{1}\right]+2\left[\mathrm{C}_{2}\right]$ keeping in mind that $\left[\mathrm{C}_{1}\right]$ and $\left[\mathrm{C}_{2}\right]$ contribute 2 TAR RNA moieties each. As in case (iv) and (v), we define a constant $Z$, which takes into account the differential migration rates of $\mathrm{C}_{1}$ and $\mathrm{C}_{2}$. The equation for the fraction of bound RNA ( $\phi$ ) can be arrived at using the above results and the final equation after simplification yields:

```
    \(\phi=\left(\left(4 * \mathrm{C}^{*}[\mathrm{~A}]^{\wedge} 3^{*}\left([\mathrm{~A}]^{\wedge} 2+\mathrm{K}_{\mathrm{d} 2}\right)-[\mathrm{A}]^{\wedge} 2^{*} \mathrm{sqrt}\left(\mathrm{K}_{\mathrm{d} 1} 2^{*} \mathrm{~K}_{\mathrm{d} 2}{ }^{\wedge} 2+8^{*} \mathrm{C}^{*}[\mathrm{~A}]^{*} \mathrm{~K}_{\mathrm{d} 1} *\right.\right.\right.\)
    \(\left.\left.\mathrm{K}_{\mathrm{d} 2} *\left([\mathrm{~A}]^{\wedge} 2+\mathrm{K}_{\mathrm{d} 2}\right)\right)+\mathrm{K}_{\mathrm{d} 1} * \mathrm{~K}_{\mathrm{d} 2} *[\mathrm{~A}]^{\wedge} 2\right)+\mathrm{Z}^{*}\left(4 * \mathrm{C}^{*} \mathrm{~K}_{\mathrm{d} 2} *[\mathrm{~A}]^{*}\left([\mathrm{~A}]^{\wedge} 2+\mathrm{K}_{\mathrm{d} 2}\right)-\mathrm{K}_{\mathrm{d} 2} * \mathrm{sqrt}\right.\)
\(\left.\left.\left(\mathrm{K}_{\mathrm{d} 1}{ }^{\wedge} 2^{*} \mathrm{~K}_{\mathrm{d} 2} \wedge 2+8^{*} \mathrm{C}^{*}[\mathrm{~A}]^{*} \mathrm{~K}_{\mathrm{d} 1}{ }^{*} \mathrm{~K}_{\mathrm{d} 2}{ }^{*}\left([\mathrm{~A}]^{\wedge} 2+\mathrm{K}_{\mathrm{d} 2}\right)\right)+\mathrm{K}_{\mathrm{d} 1}{ }^{*} \mathrm{~K}_{\mathrm{d} 2} \wedge 2\right)\right) /\left(4^{*} \mathrm{C}^{*}[\mathrm{~A}]^{*}\left([\mathrm{~A}]^{\wedge} 2+\right.\right.\)
    \(\left.\mathrm{K}_{\mathrm{d} 2}\right)^{\wedge} 2-\mathrm{K}_{\mathrm{d} 1} * \mathrm{~K}_{\mathrm{d} 2} *\left([\mathrm{~A}]^{\wedge} 2+\mathrm{K}_{\mathrm{d} 2}\right)+\left(\mathrm{K}_{\mathrm{d} 2}+[\mathrm{A}]^{\wedge} 2\right) * \operatorname{sqrt}\left(\mathrm{~K}_{\mathrm{d} 1}{ }^{\wedge} 2^{*} \mathrm{~K}_{\mathrm{d} 2} \wedge 2+8^{*} \mathrm{C}^{*}[\mathrm{~A}]^{*} \mathrm{~K}_{\mathrm{d} 1} *\right.\)
        \(\left.\mathrm{K}_{\mathrm{d} 2} *\left([\mathrm{~A}]^{\wedge} 2+\mathrm{K}_{\mathrm{d} 2}\right)\right)\) )...Equation 6
```

The experimental data can be fitted to each of the equations derived above (Equation $1,2,3,4,5$ and 6 ) to assess the quality of fit of the assumed model with respect to the experimental data.
To test how each of the equations derived for a particular model fits with the experimentally derived data as summarized in Table 3.10 (a), $\phi$ was defined as a function of the concentration of the ligand AMG in accordance with the equations discussed above. These were then fit with a linear least square fitting procedure in MATLAB and the results are discussed in Figure 3.10(c). Scripts used to simulate and plot the functions are available in APPENDIX C.

Figure 3.10 (c) Binding stoichiometry. The function $\left(D-D_{F}\right) /\left(D_{B}-D_{F}\right)$ is plotted versus the concentration of the aminoglycoside analogue AMG in each lane of the PACE gel. D is the retardation distance in each lane, $D_{F}$ is the retardation distance of the TAR RNA without AMG and $D_{B}$ is the retardation distance of the TAR RNA completely bound to AMG (concentration of $\mathrm{AMG}=500 \mu \mathrm{M}$ ). The function $\left(D-D_{F}\right) /\left(D_{B}-D_{F}\right)$ can be expressed in terms of molar fractions of bound and free RNA, according to the procedure described by Cilley and Williamson [ ${ }^{100}$ ]. Different binding models were assumed and the theoretical dependence of $\left(D-D_{F}\right) /\left(D_{B}-D_{F}\right)$ on the concentration of AMG was calculated in each case from the molar fractions assuming constant concentration of AMG in each lane. The experimental data were fitted to the theoretical functions using MATLAB to derive the binding stoichiometry for the TAR/AMG complex. Six different models were considered: (i) one molecule of the TAR RNA binds one molecule of AMG (cyan line); (ii) one molecule of the TAR RNA binds two molecules of AMG with the same $\mathrm{K}_{\mathrm{d}}$ (green line); (iii) two molecules of the RNA bind one molecule of AMG (magenta); (iv) one molecule of the TAR RNA binds two molecules of AMG with different $K_{d}$ (blue line very close to cyan line); (v) one molecule of the TAR RNA binds one molecule of AMG (TAR + AMG $\leftarrow$ $\left.\mathrm{K}_{\mathrm{d} 1} \rightarrow \mathrm{C}_{1}\right)$; subsequently the TAR/AMG complex dimerizes ( $2 \mathrm{C}_{1} \leftarrow \mathrm{~K}_{\mathrm{d} 2} \rightarrow \mathrm{C}_{2}$ ) (close to the cyan line, not shown); (vi) two molecules of the RNA bind one molecule of AMG (2 TAR+AMG $\leftarrow \mathrm{K}_{\mathrm{d} 1} \rightarrow \mathrm{C}_{1}$ ); subsequently two molecules of AMG are recruited by the RNA dimer for a total of two RNA molecules and three molecules of AMG $\left(\mathrm{C}_{1}+2 \mathrm{AMG} \leftarrow \mathrm{K}_{\mathrm{d} 2} \rightarrow \mathrm{C}_{2}\right.$. (red line; $\mathrm{K}_{\mathrm{d} 1}=20 \mu \mathrm{M}^{2} ; \mathrm{K}_{\mathrm{d} 2}=3 \mathrm{mM}^{2}$ )The best fit is obtained for case (vi), which supports the stoichiometry inferred from the NMR data (r.m.s.d 0.084).

## 4 Discussions

### 4.1 Binding of AMG to multiple spots on the upper stem

It is widely recognized that the intermolecular surface in RNA/protein complexes is rather large and therefore small molecules cannot efficiently compete with proteins for RNA binding. Despite many efforts in the search for competitive inhibitors of the Tat/TAR interaction, no drug lead has been identified to date. The major difficulty in the development of TAR-binders as potential therapeutic agents is their low specificity.

Brownian dynamics simulations of cation diffusion performed on the NMR structures of free TAR RNA $\left[{ }^{25 ; 39 ; 163 ; 164}\right.$ ] revealed three electro negative pockets in the RNA hairpin.

Fig 4.1 (a) Multiple cation binding pockets predicted by Brownian dynamics simulation in TAR RNA

The predicted cation binding sites are located on top of the U31-GG-G34 loop (orange), in the U23-C-U25 bulge (magenta), and in the deep groove of the lower stem (cyan) as shown in Figure 4.1(a). The "hot-spot" in the lower stem is particularly extended, involving the backbone of nucleotides in the upper stem, which connects the bulge and the loop. Multifunctional drugs, such as amino glycosides (AMG)
carrying several cationic groups could be expected to interact simultaneously with the lower and upper stem regions, thereby stabilizing the TAR RNA in its free conformation $\left[{ }^{30 ;} 31 ; 164\right]$. An extended effort in identifying the minimal number of interactions necessary to stabilize the Tat-bound conformation of the TAR RNA resulted in the detection of two binding sites for positively charged groups at the bulge site and in the upper stem major groove close to A27 and G28 [ ${ }^{37}$ ].

Fig 4.1 (b) Multiple interaction of amino group of the sugar moieties. Sugar 1 and 3 of AMG simultaneously interact with G28, A35 and U38 of HIV-2 TAR RNA.

Synthetic ligands exploiting both binding sites showed the highest activity and induced an RNA conformation similar to that binding to the Tat-protein [ ${ }^{13 ; 32 ; 37 ; 38 ; 57 \text {; }}$ 66; 165; 166; 167; 168; 169; ${ }^{170}$ ]. The amino groups of ligand AMG contact both the bulge site and the major groove functional groups at the G28 site (Figure 4.1(b)). Although the interaction with the bulge is suboptimal and could be improved by introducing a guanidinium group at the C 1 or C 5 of sugar- 5 , the amino group of sugar- 3 nicely interacts with the electron-rich spot at the G28 and U38 site as shown in Figure 4.1(b). Additionally, the amino group of sugar-1 interacts with the loop residue A35. Also, the intermolecular NOEs to G36 from AMG to H8 and the partial
rearrangement of the hexanucleotide loop as suggested by the stacking of G34 on G36 suggests that that this large but flexible scaffold of AMG allows reaching multiple binding sites on the TAR RNA, and therefore represents a valuable starting structure for the design of binders that explore a large surface of the TAR upper stem.

The conformation induced by AMG at the bulge site of the TAR RNA, as well as the relative orientation of the two stems is markedly different from that found in the TAR/argininamide complex which is accompanied by the formation of the U23-A27U38 base triple and subsequent coaxial stacking of the upper stem on the lower stem. In contrast, the bulge nucleotides are solvent exposed in the TAR RNA/AMG complex and the upper stem is oriented at an angle of $60^{\circ}$ with respect to the lower stem (Fig 4.1 (c)). The disruption of the A22-U40 base pair leads to the relative position of the two stems, thus allowing the tilting of A22 to accommodate the large ligand and of the electrostatic interactions of AMG amino groups with the phosphate of A22. The sugars and linkers of AMG show extensive hydrophobic contacts with U23 and U25 rings which are characteristic of a well-known interaction motif in complexes of proteins with oligosaccharides, where the sugars usually stack below aromatic side chains [ ${ }^{157 ; 163}$ ].

Fig 4.1 (c) The TAR RNA argininamide structure on the left reveals the co-axial stacking of the upper stem on the lower stem. In contrast, the upper stem is tilted at an angle of approximately $60^{\circ}$ with respect to the lower stem in the TAR RNA/AMG complex on the right. (Figures generated with Pymol [DeLano Scientific] and CURVES [ ${ }^{171}$ ])

The hexanucleotide apical loop (residues 30 to 35) has been found to be quiet flexible in previous NMR studies on the TAR RNA, with the ribose of C30, G33 and G34
averaging between C2' endo and the C3' endo conformations. Further, studies on a 14 and 19 nucleotide hairpin containing the TAR hexanucleotide loop revealed the stacking of A35 on G36 and of G34 on G36 [ ${ }^{172}$ ]. On the basis of such structural information, it was proposed that the apical loop is stabilized by base stacking on both sides and possibly by the formation of base pairs between C30 and A35 or C30 and G34 [ ${ }^{173}$ ]. In a more recent work, biochemical analysis of native and mutant TAR RNAs was used together with MD simulations to show that the apical loop of the TAR RNA is stabilized by a cross-loop base pair between C30 and G34, with A35 projected out of the loop $\left[{ }^{174}\right]$. This observation does not necessarily contradict the NMR studies hypothesizing the stacking of A35 on G36. The large line broadening of the A35-C2 resonance of the free TAR RNA and the NOEs between the bases of G34, A35 and G36 are consistent with A35 being in equilibrium between the stacked and looped-out conformations. The binding of AMG to the TAR RNA however eliminates this equilibrium. This is supported by the disappearance of NOE contacts between the base of A35 to those of G34 and G36, while several NOEs appear between the bases of G34 and G36. This suggests the stacking of G34 over G36. While G34 stacks on G36; the formation of C30-G34 base pair becomes possible even though no evidence of such a base pair is found in the TAR RNA/AMG complex. In the stacked conformation, the N7 and O6 functional groups of G34 assume welldefined positions in the major groove and the formation of the C30-G34 base pair becomes possible. MD simulations also suggest that G34 adopts a C3' endo conformation when G34 stacks upon G36. This is in agreement with our observation wherein we find that in all the structures of the TAR RNA/AMG complex, the ribose of G34 adopts the C3' endo conformation, in spite of the sugar pucker remaining unrestrained during the molecular dynamics protocol.

Fig 4.1 (d) G34 is positioned on top of G36. A35 interacts with the ligand and therefore moves out of the loop. As a consequence, G34 moves on top of G36. The two bases interact either face to face (A) or face to edge (B). This is indicative of two conformations in intermediate exchange in the microsecond to millisecond time scale. Further, the line width of C8 resonance of G34 also confirms this.

Modeling studies involving artificial restraints between C30-G34 enforcing the formation of a base pair in the hexanucleotide loop in the TAR RNA/AMG complex lead to formation of structures, which satisfy such constraints and do not lead to the violation of other experimental restraints and high energy. In summary, our data reveal that binding of a cationic ligand of appropriate size, simultaneously to the bulge and the loop of the TAR RNA on the major groove side of the upper stem leads to the stabilization of the looped out conformation of A35 and subsequently to the stacking of G34 on top of G36 [ ${ }^{101}$ ]. Given the very large intermolecular surface in RNA/protein complexes, small molecules cannot efficiently act as competitive inhibitors to proteins for RNA binding. Despite many efforts in this direction, the search for a competitive inhibitor of the TAT/TAR RNA interaction has not met with much success because of toxicity or low specificity. The scaffold of AMG thus represents a promising class of aminoglycosides for the development of new TAR RNA binders that maybe used to address this problem, due to the following reasons:

1) Cyclic structure and flexibility of AMG allows functional groups to bind to multiple sites on the RNA.
2) AMG interacts with A 35 of the hexanucleotide loop, leading to partial rigidification and restructuring of the previously unstructured loop, in a manner that may be suggestive of that required for the binding of CyclinT1 to the TAR RNA.

### 4.2 Cyclic Scaffold of AMG

The value of cyclic structures as a conformationally constrained backbone for TAR binders has been proven by the design of peptidomimetics based on a cyclic, beta-hairpin-like scaffold $\left[{ }^{[170}\right]$, binding the TAR RNA with a much higher affinity than the linear analogs [ ${ }^{91 ;}{ }^{170}$ ]. The structure of the BIV (Bovine Immunodeficiency Virus) TAR RNA bound to one of these peptidomimetics revealed extensive interactions with the upper stem major groove, including a conserved hydrophobic contact of an Isoleucine residue with the bulged-out Uridine of the base triple as well as electrostatic contacts of Arginine side chains with the tetra loop capping the upper stem and with the second and third base pairs of the upper stem [ ${ }^{170}$ ]. Intermolecular interactions of similar nature are found for the TAR/AMG complex. Analogous to the BIV TAR RNA/peptide complex, AMG uses hydrophobic contacts to bind to the bulge pyrimidines and electrostatic contacts to bind to the major groove face of the upper stem base pairs and to the loop residues. As observed for the peptides, linear neooligoaminodeoxysaccharides show a much lower affinity for the TAR RNA than their cyclic analog AMG [ ${ }^{91}$ ].

Figure 4.2 Cyclically restrained analogues as a tool to target the bulge and the loop of the TAR RNA simultaneously. The BIV TAR RNA/peptide complex on the right and the TAR RNA/AMG complex on the left offer analogous examples of cyclically restrained ligands targeting the bulge and the loop of the TAR RNA simultaneously. The ligands are colored red.

### 4.3 Comparison of the binding of AMG to TAR RNA complex with the binding of CyclinT1 to the TAR loop

It was believed for many years that sequences in the apical loop of TAR RNA are not required for Tat binding even though this region of the RNA is essential for efficient trans-activation $\left[{ }^{175}\right]$. Genetic studies implied that the loop acts as a binding site for cellular co-factors of Tat, however the identity of the loop factor remained mysterious and controversial for many years. The first evidence identifying the cellular co-factor required for loop recognition was obtained by Wei et al. [ ${ }^{59}$ ] who reported that CyclinT1, a subunit of P-TEFb complex, can form a stable ternary complex with Tat and TAR RNA that could be detected by gel electrophoresis. Ternary complex formation requires both the Tat binding site on TAR as well as the loop sequence. Further, the formation of the Tat/TAR complex is required for the phosphorylation and subsequent activation of the RNA polymerase stalled at the TAR RNA site. The interaction site of CyclinT1 with the TAR RNA is localized in the apical loop. The two atoms O6 and N7 of G32 and G34 and the presence, but not the nature, of a nucleotide in position 35 are essential for the interaction. This was confirmed by monitoring the effect of base substitution on the affinity of the TAR RNA for the TatCyclinT1 complex and observing the efficiency of binding in a deletion mutant for the residue $35\left[{ }^{176}\right]$. Results indicated a dramatic reduction in the binding efficiency of the TAR RNA with the Tat-CyclinT1 complex when the normal TAR RNA sequence with the hexanucleotide loop was replaced with a deletion mutant at residue 35 (pentanucleotide loop). On substituting the guanine residues at positions 32 and 34 with adenine, a loss in binding affinity was observed. Further, if these guanine residues were substituted with a cytosine, then a dramatic loss in binding efficiency ensued. This could be reasoned out based on the chemical structure of the nucleotides in question. While the guanine moiety is not only capable of functioning as a hydrogen bond acceptor at the O6 site of the carbonyl group, it has also a electron rich Nitrogen at position 7 capable of functioning as an electron donor in the purine ring. Compared with guanine, adenine contains only the electron rich N7 but lacks the O6 hydrogen bond acceptor. In stark contrast, the cytosine nucleotide contains an amino group (hydrogen bond donor) in place of the carbonyl group (hydrogen bond acceptor) and also N7 is absent. Thus, the importance of the N7 and O6 at positions

32 and 34 can be rationalized based on the efficiency of RNA-protein complex formation in different mutants and the chemical structure of the nucleotides.

The mechanism by which the Tat protein favors the interaction of CyclinT1 with the apical loop is not known, although it is reasonable to hypothesize that Tat structurally pre-organizes the RNA for the binding of CyclinT1. On the basis of the structure of the complex of TAR with the aminoglycoside analogue AMG, we propose an explanation for the dependence of the TAR/CyclinT1 interaction on the Tat/TAR complex formation, which fits well the biochemical data summarized above. We suggest that the binding of Tat to TAR pre-organizes the hexanucleotide loop in a favorable conformation for CyclinT1 binding. It is conceivable that the arginine-rich stretch of the Tat protein, which is responsible for TAR binding at the bulge site, also contacts the A35 residue of the hexanucleotide loop and blocks it in its looped-out conformation, in a similar way as our aminoglycoside. The major driving force for this contact could be the interaction of an aromatic $\pi$ orbital with a cation, similarly to that observed for the TAR RNA/AMG complex. A generic $\pi$-cation interaction provides a rationale for the insensitivity of the TAR/CyclinT1 interaction to the nature of the nucleotide at position 35. A small negative effect on complex formation is observed exclusively for the A35G mutant, where a possible cross-loop C30-G35 base pair would destabilize the looped-out conformation of the nucleotide in position 35. Supporting our hypothesis, affinity-cleaving experiments show that F38 of Tat is located in the proximity of nucleotide 34 and 35 of the TAR RNA [ ${ }^{177}$ ]. Furthermore, the residue K 50 of the Tat-protein has been found to cross-link with the TAR nucleotide 34 , and this interaction is considerably enhanced by the binding of CyclinT1 to the Tat/TAR complex $\left[{ }^{176}\right]$. In the TAR RNA/AMG complex, the loopedout conformation of A35 is accompanied by the relocation of G34 upon G36. Analogously, in the Tat/TAR complex stacking of G34 upon G36 would place the O6 and N7 atoms of G34, which are essential for the binding of CyclinT1, in a welldefined position in the major groove of the TAR RNA. The formation of a base pair between C30 and G34 would further stabilize the position of the G34 functional groups. In fact, such base pair has been shown to favor the interaction of the TAR RNA with CyclinT1 without being directly involved in the complex formation $\left[{ }^{176}\right]$. Based on the irrelevance of the nucleotide nature at position 35, it has been hypothesized that this nucleotide functions as a spacer with no direct contact to the
proteins. Contrarily, we suggest that A35 could be the basis of a regulation mechanism for the formation of the Tat/TAR/CyclinT1 complex based on the conformational stability of the hexanucleotide loop.

### 4.4 The lower stem binding site and dimerization

Figure 4.4 Two views of the dimer interface between the TAR RNA. Above is the top view of the dimer. The residues 43 and 44 are marked in green and blue respectively. The picture below offers a side view of the ligand in red at the dimer-forming interface.

As described in section 4.1, the TAR RNA has multiple "hot spots" capable of acting as attractive targets of cationic moieties. Previous studies involving neomycin B are proof of the minor groove of the lower stem of the TAR RNA forming a negatively charged cleft that forms an attractive binding site for aminoglycosides. Thus, it isn't surprising that the aminoglycoside analogue AMG also displays similar behavior, binding to the minor groove of the TAR RNA, sandwiched between the parallel, lower stems of two adjacent TAR RNA molecules. Furthermore the TAR/AMG complex dimerizes. A model invoking oligomerization of the TAR RNA/AMG complex through the molecule of AMG bound to the lower stem minor groove is compatible with all experimental data. This process is likely to be favored by the
appropriate size of the constrained cyclic structure of AMG that allows it to simultaneously contact both the TAR RNAs.

### 4.5 Significance for drug design

In principle, targeting the interaction between the Tat protein and TAR RNA should be a sufficient condition to induce an inhibition of the transcription mechanism and lead to a decrease of full-length viral transcripts essential for the activity and pathogenicity of the Human Immunodeficiency virus. However, considering that biological systems are not static, and that proteins and nucleic acids present a certain degree of plasticity due to the pre existence of conformational populations, the traditional single drug-single target approach maybe (should be) replaced by single drug-multiple target approach $\left[{ }^{178}\right]$. However, it is essential to counterbalance this affinity of the drug towards multiple targets with specific recognition and a high degree of affinity towards these specific targets. The novel cyclic aminoglycoside, AMG, introduced as an attractive scaffold that can serve as the basis for the design of promising future leads to target the Tat-TAR interaction, is an example of how a single drug-multiple target moiety may function.
It maybe possible to exploit the "promiscuous" behavior of an AMG based drug to target different sites, each of vital essence for the binding of different proteins required for biological activity, in this instance, simultaneously inhibit the interaction of the Tat protein with the bulge of the TAR RNA and the interaction of CyclinT1 with the hexanucleotide loop of the TAR RNA.

## 5. Conclusion and Perspectives

This thesis makes a contribution towards the understanding of the mechanism underlying the interaction of the Tat protein with the TAR RNA and how aminoglycosides based on a cyclic scaffold can afford a tool to explore RNA recognition by cationic entities. State of the art NMR methodology complimented with biochemical techniques was employed to arrive at the structure of the RNA in complex with the aminoglycoside analogue.
The structure reveals two ligand-binding sites. The first spans from the bulge to the loop of the TAR RNA on the major groove side of the upper stem. In particular, AMG interacts with the residue A35 of the RNA capping loop, thereby inducing partial structuring, while simultaneously binding to the bulge residues resulting in obstruction and inhibition of the Tat protein/TAR RNA and Tat/TAR RNA/CycT1 complex formation. The minor groove in the lower stem of the TAR RNA forms the second site capable of binding AMG.
The structural rearrangement of the loop may resemble and be part of a necessary conformational change of the TAR RNA induced by the Tat protein for the binding of CyclinT1. Biological processes are usually concerted in nature and interfering with one process may necessarily cause an affect in subsequent interactions necessary for biological activity. The interaction of this novel aminoglycoside is an example of how an organic moiety can interfere with a necessary interaction (i.e. that of Tat protein and TAR RNA), provide insights into how further activities that precede the Tat/TAR interaction are regulated and how this mechanism can be exploited to design better scaffolds based on the structure of this organic moiety (AMG) for a new generation of TAR binders that can simultaneously inhibit both the Tat/TAR RNA and the Tat/TAR/CycT1 complex formation.

Aminoglycosides have since long, formed an integral part of the armory at the disposal of chemists, to not only better explore the realm of RNA recognition by cations, but also an extremely valuable source of drugs used to target a wide variety of diseases prevailing in the world. However, lack of specificity and the quick development of resistance against such aminoglycosides by pathogenic organisms fuel the urgent need to design and synthesize new and novel scaffolds of antibiotics that would be more effective in curbing diseases. The author believes that the work
carried out in this thesis paves the way for the design of a promising generation of lead compounds that exhibit specific affinity towards the TAR RNA, while simultaneously contacting two sites which are of paramount importance for the binding of Tat protein and the CyclinT1 complex. These compounds would be novel in the fact that they would facilitate interference with the TAR-Tat and TAR-TatCyclinT1 interaction in a cooperative way.

It is also the author's hope, that the conclusions reached in this work will be a fruitful source of further experiments that may eventually lead to a deeper understanding of HIV pathogenicity and the underlying mechanism.

## Appendix B

## RESTRAINED MOLECULAR DYNAMICS PROTOCOL

## 1) HIGH TEMPERATURE

a) Temperature: 1000 K
b) Number of structures generated: 150
c) Energy terms: bonds, angles, Vdw, NOE, plan, impr and cdih
d) Force constants employed:
$\mathrm{NOE}=50.0$
Cdih=300.0
Vdw=4.0
e) Energy cutoff $600 \mathrm{kcal} / \mathrm{mol}$ (total) and $100 \mathrm{kcal} / \mathrm{mol}$ (NOE)

## 2) SIMULATED ANNEALING

100 steps of Powell energy minimization including bonds, vdw, NOE, angl, plan, cdih and impr
a) 3 rounds of 3 ps dynamics at 1000,600 and 400 K with 700 steps of Powell minimization between the dynamics.
b) 1000 Powell energy minimization in the end.
c) Hydrogen bonding restraints between A22-U40 removed
d) Energy cutoff $400 \mathrm{kcal} / \mathrm{mol}$ (total) and $50 \mathrm{kcal} / \mathrm{mol}$ (NOE)

## 3) REFINEMENT

a) 2 ps dynamics at $500,300,150,50$ and 10 K each with 1000 steps of Powell minimization between each step.
b) Calculations ended with 2000 steps of Powell minimization.
c) Energy cutoff $25 \mathrm{kcal} / \mathrm{mol}(\mathrm{NOE})$
d) All chosen structures had only 0 to 4 NOE violations greater than $0.2 \AA$ and none greater than $0.5 \AA$ and no angular violations greater than $5^{\circ}$.

## 4) REFINEMENT WITH fiRDCs

a) Switch on attractive Lennard-Jones non-bonded parameter.
b) 75 cycles, 1000 steps of molecular dynamics at 300 K during which $\mathrm{K}_{\text {sani }}$ was increased from 0.001 to $1.5 \mathrm{kcal} / \mathrm{mol} \mathrm{Hz}^{-2}$.
c) 3 rounds of 5 ps dynamics at $300,150,50$ and 10 K while all force constants were switched to their maximum value.
d) 2000 steps of Powell minimization.

Protocols for initial structure generation, simulated annealing, refinement refinement with field induced Residual Dipolar Couplings used in XPLOR-NIH for the generation of structures of HIV-2 TAR-RNA/AMG.

## Curriculum Vitae

## Personal data

Name Devanathan Raghunathan
Date of birth
Place of birth
Citizenship
$15^{\text {th }}$ March 1980
Secunderabad, India
Indian

## Education

03/1996 All India Secondary School Examination
03/1998
05/2001 Bachelor of Science (with Honors) Chemistry, University of Delhi

05/2002-
07/2002 Internship at Bayer AG Leverkusen, Department of Polymers Funded by AIESTE and DAAD

08/2003 Master of Science Chemistry, Indian Institute of Technology Madras, Thesis titled "Application of Floquet theory and van Vleck transformations to pulse sequences in NMR" under the supervision of Prof. Dr. Mangala Sunder Krishnan

08/2003-
03/2007
PhD. in the department of NMR based Structural Biology at the Max Planck Institute for Biophysical Chemistry pursued under the guidance of Prof. Dr. Christian Griesinger. Thesis titled "TAR-RNA Recognition by a Novel Cyclic Aminoglycoside Analogue"

## Lebenslauf

## Persönliche Daten

Name Devanathan Raghunathan
Geburtstag $\quad 15.3 .1980$
Geburtsort Secunderabad, Indien
Staatsangehörigkeit Indisch

## Education

03/1998 Allgemeine Hochschulreife, Delhi
05/1998 Beginn des Studium der Chemie an der Universität Delhi
05/2001 Bachelor of Science in Chemie (mit Auszeichung), Universität Delhi

05/2002-
07/2002
Praktikum bei der Bayer AG Leverkusen, Abteilung fuer Polymerentwicklung (finanziert durch ein Stipendium des DAAD und AIESTE).

08/2003

08/2003-03/2007
Master of Science in Chemie, Indisches Institut für Technology, Madras, Titel der Arbeit "Anwendung des Floquet Theorems und van Vleck Transformationen auf Pulssequenzen in der NMR-Spektroskopie" unter Anleitung von
Prof. Dr. Mangala Sunder Krishnan
Doktorarbeit am Max-Planck-Institut für Biophysikalische Chemie, Abteilung NMR-basierte Strukturbiologie (Prof. Dr. C. Griesinger), Titel der Arbeit: "Erkennung von TAR-RNA durch ein neues zyklisches Aminoglycosid-Analog".

[^0]:    

    Fig 2.5.7 (a) The common conformations exhibited by ribose sugars in RNA, C3'-endo and C2'-endo. Observe how the positions of H1' and H2' get altered with change in sugar pucker. (b) Dihedral angles associated with a nucleotide.
