

The interplay of SmNBR1 and SmATG8 in  
selective autophagy of the filamentous fungus  
*Sordaria macrospora*

Dissertation  
for the award of the degree  
**“Doctor rerum naturalium”**  
of the Georg-August-Universität Göttingen

within the doctoral program “Microbiology and Biochemistry”  
of the Georg-August University School of Science (GAUSS)

submitted by  
**Antonia Werner**  
from Leinefelde

Göttingen, 2017

**Thesis Committee:**

**Prof. Dr. Stefanie Pöggeler**, Department of Genetics of Eukaryotic Microorganisms, Institute of Microbiology and Genetics

**Prof. Dr. Gerhard Braus**, Department of Molecular Microbiology and Genetics, Institute of Microbiology and Genetics

**Prof. Dr. Michael Thumm**, Department of Cellular Biochemistry, University Medical Center Göttingen

**Members of the Examination Board:**

**Referee: Prof. Dr. Stefanie Pöggeler**, Department of Genetics of Eukaryotic Microorganisms, Institute of Microbiology and Genetics

**2<sup>nd</sup> Referee: Prof. Dr. Gerhard Braus**, Department of Molecular Microbiology and Genetics, Institute of Microbiology and Genetics

**Further members of the Examination Board:**

**Prof. Dr. Michael Thumm**, Department of Cellular Biochemistry, University Medical Center Göttingen

**Prof. Dr. Heike Krebber**, Department of Molecular Genetics, Institute of Microbiology and Genetics

**Jun. Prof. Dr. Kai Heimel**, Department of Molecular Microbiology and Genetics, Institute of Microbiology and Genetics

**PD Dr. Fabian Commichau**, Department of General Microbiology, Institute for Microbiology and Genetics

Date of oral examination: 28.03.2017

## **Affirmation**

I hereby declare that this thesis was written independently and with no other sources and aids than quoted.

Göttingen, 02.02.2017

Antonia Werner

## **Publication based on this thesis**

This doctoral study was performed in the group of Prof. Dr. Stefanie Pöggeler in the Department of Genetics of Eukaryotic Microorganisms at the Institute of Microbiology and Genetics, Georg-August University Göttingen.

Some parts of the results section of this doctoral study were peer-reviewed and published in the journal “PLOS ONE”.

**Antonia Werner**, Britta Herzog, Stefan Frey and Stefanie Pöggeler (2016). **Autophagy-associated protein SmATG12 is required for fruiting-body formation in the filamentous ascomycete *Sordaria macrospora***. PLOS ONE/DOI: 10.1371/journal.pone.0157960.

Accepted manuscript online: 16. June 2016.

## V. List of abbreviations

aa	amino acids
3-AT	3-amino-1,2,4-triazol
AD	activation domain
ADE2	enzyme involved in adenine synthesis
A. dest.	<i>Aqua destillatum</i>
Atg	autophagy-related gene
<i>amp<sup>R</sup></i>	ampicillin resistance
BD	binding domain
BiFC	Bimolecular fluorescence complementation experiments
BLAST	basic local alignment and search tool
BMM	biomalt maize medium
bp	base pair
CC	coiled coil
cDNA	complementary DNA
CFP	cyan fluorescence protein
<i>cm<sup>R</sup></i>	chloramphenicol resistance
Co-IP	Co-immunoprecipitation
CR	conserved region
C-terminus	carboxy-terminus
C-terminal	carboxy-terminal
Cvt	cytoplasm-to-vacuole targeting
DAPI	4',6-Diamidino-2-Phenylindole, Dihydrochloride
DIC	differential interference contrast
DNA	deoxyribonucleic acid
dNTP	2'-deoxy-nucleotids-5'triphosphate
<i>Dsred</i>	encodes red fluorescence protein of <i>Discosoma sp.</i>
DTT	dithiothreitol
ect	ectopical integrated
<i>egfp</i>	encodes enhanced green fluorescence protein of <i>Aequorea victoria</i>
ER	endoplasmic reticulum
EtBr	ethidium bromide
EtOH	ethanol
final conc.	final concentration
Gal4-AD	encodes the activation domain of the Gal4-transcription factor of <i>Saccharomyces cerevisiae</i>
Gal4-BD	encodes the binding domain of the Gal4-transcription factor of <i>Saccharomyces cerevisiae</i>
gDNA	genomic DNA
<i>HIS3</i>	enzyme for histidine biosynthesis
<i>hph</i>	hygromycin B-phosphotransferase
<i>hyg<sup>R</sup></i>	hygromycin resistance
JUBA	juxta UBA
<i>kan<sup>R</sup></i>	kanamycin resistance
kb	kilobase
kDa	kilo dalton
LC3	light chain 3
LC/MS	liquid chromatography-mass spectrometry

## List of abbreviations

---

<i>LEU2</i>	enzyme involved in leucine biosynthesis
LIR	LC3-interacting region
nat	nourseothricin
<i>nat</i> <sup>R</sup>	nourseothricin resistance
NBR1	neighbor of BRCA1 gene1
nt	nucleotide
N-terminus	amino-terminus
N-terminal	amino-terminal
OD	optical density
ORF	open-reading frame
P	phosphate
P	promoter
PAGE	polyacrylamide gel electrophoresis
PAS	phagophore assembly site
PB1	phox and bem1
PCR	polymerase chain reaction
PI3K	phosphatidylinositol 3-kinase
PtdIns	phosphatidylinositol
PE	phosphatidylethanolamine
PEG	polyethylene glycol
RNA	ribonucleic acid
rpm	revolutions per minute
RT	room temperature
SDS	sodium dodecyl sulphate
ssi	single-spore isolate
<i>S.m.</i>	<i>Sordaria macrospora</i>
SQSTM1	sequestosome 1
SWG	Sordaria Westergaards medium
T	terminator
TOR	target of rapamycin
<i>TRP1</i>	enzyme involved in tryptophan biosynthesis
<i>trpC</i> <sup>T</sup>	terminator of the anthranilate synthase gene of <i>Aspergillus nidulans</i>
Ub	ubiquitin
UBA	ubiquitin association
UBL	ubiquitin-like protein
<i>URA3</i>	enzyme involved in uracil biosynthesis
UTR	untranslated region
Vps	vacuolar protein sorting
Y2H	yeast-two hybrid
YFP	yellow fluorescence protein
wt	wild type
ZZ	zinc-finger domain

Common used abbreviations and units of measurement are not enlisted.

## Summary

Autophagy is a conserved ubiquitous degradation process in eukaryotic cells which is mainly investigated in the baker's yeast *Saccharomyces cerevisiae*. It includes the random sequestration of defective and excessive proteins and organelles within a double-membraned autophagosome. In filamentous fungi, the main purposes of autophagy are the regulation of starvation adaptation and developmental processes. In yeast, 41 autophagy-related genes (*atg*) exist from which many are conserved in the homothallic ascomycete *Sordaria macrospora* (Sm). One of the core autophagy genes is *atg12* which is essential for autophagosome formation. Yeast-two hybrid analysis revealed a physical interaction of SmATG12 with both SmATG7 and SmATG3. A homokaryotic *Smatg12* knockout strain could be generated which displayed reduced vegetative growth under nutrient-starvation conditions and was unable to form fruiting bodies. EGFP-labeled SmATG12 was detected in the cytoplasm and as punctate structures presumed to be phagophore structures. Furthermore, delivery of EGFP-labeled SmATG8 to the vacuole was entirely dependent on SmATG12.

In contrast to non-selective bulk autophagy, selective autophagy is characterized by cargo receptor proteins, which bind specific cargos such as organelles, damaged or harmful proteins or microbes for their autophagic degradation. The selective autophagy of protein aggregates and surplus organelles such as peroxisomes, mitochondria, ribosomes and nuclei is referred to as aggre-, pexo-, mito-, ribo-, and nucleophagy, respectively. By a GFP-Trap analysis followed by liquid chromatography mass spectrometry (LC/MS) using the core autophagy protein SmATG8 as bait SmNBR1 was identified, which is a putative homolog of the human autophagy cargo receptor neighbour of BRCA1 (NBR1). SmNBR1-DsRED co-localizes with EGFP-SmATG8 at autophagosomes-like structures and in vacuoles. The interaction of both proteins was confirmed by means of yeast-two hybrid experiments, BiFC and Co-IP. Deletion of *Smnbr1* leads to impaired vegetative growth under starvation conditions and fruiting-body development that is characterized by a drastically reduced number of perithecia and mature ascospores. The phenotypically defects could be rescued by complementing the  $\Delta$ *Smnbr1* mutant with full-length *Smnbr1* as well as partially with a human *nbr1* homolog. Additionally, *Smnbr1* is involved in pexophagy. A  $\Delta$ *Smnbr1* mutant is neither able to use fatty acids as sole carbon source nor able to form fruiting bodies on H<sub>2</sub>O<sub>2</sub>-containing medium. The detection of numerous ribosomal subunit proteins in a GFP-Trap analysis using SmNBR1 as bait suggested that SmNBR1 is also involved in ribophagy. Quantitative Western-blot experiments and fluorescence microscopy revealed that degradation of SmRPL25-EGFP, a 60S ribosomal subunit protein, is impaired in  $\Delta$ *Smnbr1*. Thus, it might be that SmNBR1 is the long-sought-after ribophagy receptor for the large ribosomal subunit.

## Zusammenfassung

Autophagie ist ein Abbauweg, der in allen Eukaryonten konserviert ist. Um die Zelle auch unter Mangelbedingungen mit Nährstoffen versorgen zu können, werden in diesem Prozess nicht gebrauchte oder beschädigte Proteine und Organellen in den Vakuolen bzw. den Lysosomen abgebaut und der Zelle zur Verfügung gestellt. Der Autophagieprozess ist sehr gut in *Saccharomyces cerevisiae* analysiert und bislang konnten 41 (*atg*) Autophagiegene beschrieben werden von denen auch einige in dem filamentösen Ascomyceten *Sordaria macrospora* (Sm) identifiziert wurden. Eines der Hauptautophagiegene ist *atg12*, welches für die Autophagosomenbildung essentiell ist. In `Yeast-two hybrid` Experimenten konnte eine physikalische Interaktion von SmATG12 mit SmATG7 und SmATG3 gezeigt werden. Zur funktionellen Charakterisierung des *Smatg12* Gens wurde ein Deletionsstamm  $\Delta$ Smatg12 erstellt, welcher keine Perithezien bildet und somit steril ist. Der Phänotyp konnte durch Komplementierung bestätigt und verifiziert werden. Das Protein EGFP-SmATG12 konnte im Zytoplasma in Form von Punkten lokalisiert werden, welche voraussichtlich die `Phagophore` darstellen.

Neben der nicht-selektiven Autophagie existieren auch selektive Autophagieprozesse, bei denen ein Cargo-Rezeptor ein spezifisches Organell, aggregierten Proteinkomplex oder Mikroben erfasst und selektiv abbaut. Der Abbau von Proteinaggregaten oder Organellen wie z. B. Peroxisomen, Mitochondrien, Ribosomen und Zellkernen wird jeweils als Aggre-, Pexo-, Mito-, Ribo-, und Nukleophagy beschrieben. In einer GFP-Trap und anschließender `liquid chromatography mass spectrometry` (LC/MS) Analyse konnte das Protein SmNBR1 als Interaktionspartner von SmATG8 identifiziert werden, welches als menschlicher Autophagie Cargo-Rezeptor neighbour of BRCA1 (NBR1) bekannt ist. SmNBR1-DsRED ko-lokalisiert mit EGFP-SmATG8 an Autophagosomen und in Vakuolen. Die Interaktion der beiden Proteine konnte durch Yeast-two hybrid, BiFC und Co-IP bestätigt werden. Eine Deletion von *Smnbr1* in *S. macrospora* wurde morphologisch untersucht und zeigt Defekte in der Fruchtkörperentwicklung wie auch das Wachstum unter Aminosäuremangel war stark reduziert. Der Phänotyp konnte durch Komplementierung des *Smnbr1* Genes bestätigt werden, was auch partiell durch das menschliche *nbr1* Homolog gezeigt werden konnte. Außerdem ist SmNBR1 in Pexophagie involviert, da  $\Delta$ Smnbr1 nicht in der Lage ist Fruchtkörper auf Medium mit langkettigen Fettsäuren als Kohlenstoffquelle sowie auf Medium mit H<sub>2</sub>O<sub>2</sub> zu bilden. In GFP-Trap Analysen mit SmNBR1 als Köderprotein konnten viele ribosomale Proteine identifiziert werden. Quantitative Western-blot Experimente und Fluoreszenzmikroskopie zeigten, dass der Abbau von SmRPL25-EGFP, ein Protein der 60S ribosomalen Untereinheit, im  $\Delta$ Smnbr1 verringert ist. SmNBR1 könnte daher der bislang noch nicht bekannte Rezeptor der Ribophagie sein.

# 1. Introduction

## 1.1 Overview of autophagy in eukaryotes

Autophagy is an intracellular lysosomal (vacuolar) degradation process of cytoplasmic components (Cuervo 2004). It has a great variety of physiological and pathophysiological roles in eukaryotic cells and is conserved from yeast to man. The main purposes of autophagy are the regulation of starvation adaptation and developmental processes, clearance of old or defective intracellular proteins, organelles or invading microorganisms (Mizushima 2005; Wen and Klionsky 2016). In humans, defects in autophagy are involved in the etiology of numerous diseases, including cancer and neurodegenerative diseases (Yorimitsu and Klionsky 2005b; Milisav et al. 2015), whereas in fungi, defects in autophagy can cause impairment of multicellular development and reduced vegetative growth of fungal hyphae or defects in pathogenicity (Voigt and Pöggeler 2013a).

Although, autophagy is thought to be predominantly a cell-survival mechanism not only for restoring intracellular nutrient supply during starvation, it is also required for quality control to protect the cell against damages caused by toxic macromolecules and damaged organelles (Levine and Kroemer 2008; Mizushima et al. 2008).

Three distinct autophagy mechanisms have been described: macroautophagy, microautophagy, and chaperone-mediated autophagy (CMA) (Figure 1). Macroautophagy is the invagination of random or selected cytosolic contents by a double membrane of an autophagosome, whereas the direct uptake at the lysosomal or vacuolar membrane is termed microautophagy (Pollack et al. 2009; Li et al. 2012; Reggiori and Klionsky 2013). In micro- and macroautophagy, the cell content is degraded within the lysosome or the vacuole. In contrast to these two conserved pathways, CMA has been only found in mammals and does not rely on core autophagy-related (*atg*) genes (Okamoto 2014). The CMA is responsible for the degradation of specific cytosolic substrate proteins in cooperation with chaperones which bind target substrates. For this, proteins contain a targeting motif that is recognized by the cytosolic chaperone heat shock cognate protein of 70 kDa (HSC70). Afterwards, substrate proteins bind to the lysosomal receptor lysosome-associated membrane protein type 2A (LAMP-2A) and get translocated into the lysosomal lumen assisted by the chaperone. Once in the lysosomal matrix, substrate proteins are rapidly degraded by lysosomal proteases (Massey et al. 2004).

**Figure 1: Overview of autophagy processes.**

(A) Macroautophagy begins with the formation of a double membrane to form the PAS (phagophore assembly site). The membrane elongates to sequester cellular elements, including organelles and proteins, within an autophagosome. The autophagosome moves to a vacuole/lysosome for fusion with its outer membrane. The autophagic body will be degraded by hydrolytic enzymes in the vacuole/lysosome for nutrient supply. (B) In microautophagy, an invagination of the vacuolar/lysosomal membrane allows the direct uptake of cytosolic components such as organelles and proteins for degradation by hydrolases. (C) CMA is specific for the removal of cytosolic proteins with a pentapeptide motif recognized by the chaperone protein HSC70. Binding of this complex to the lysosomal LAMP-2A receptor leads to protein internalization and degradation in the lysosome.

Macroautophagy is the best studied and characterized process, and therefore it is often termed “autophagy”. Most of our current knowledge on autophagy was provided by a series of genetic screens in the yeast *Saccharomyces cerevisiae*, which was established as a good model organism to explain the autophagy mechanism (Suzuki and Ohsumi 2007).

## 1.2 Macroautophagy in the yeast *S. cerevisiae*

Since the 1990s macroautophagy of the baker’s yeast *S. cerevisiae* represents the best-studied autophagy system (Cao et al. 2008). Mutant screenings in different yeast species like *S. cerevisiae*, *Pichia pastoris* and *Hansenula polymorpha* identified 41 so called *atg* genes, of which 19 are required for all autophagy-related pathways while the others are involved in the

induction of specific autophagy processes in response to different physiological conditions, and in selective autophagy (Ohsumi 2001; Araki et al. 2013; Nazarko 2014; Mochida et al. 2015; Noda and Inagaki 2015; Yao et al. 2015). Beside the non-selective bulk autophagy, selective autophagy is characterized by cargo receptor proteins, which are able to bind a specific cargo such as organelles, proteins or microbes for their autophagic degradation (Kraft et al. 2010; Stolz et al. 2014; Zaffagnini and Martens 2016).

Macroautophagy can be distinguished in the consecutive steps of induction, nucleation, expansion and vesicle closure, fusion with the vacuole and breakdown of the cargo (Rubinsztein et al. 2012) (Figure 2). The induction of the process promotes the *de novo* synthesis of the autophagosomal double membrane and occurs in *S. cerevisiae* under nutrient starvation conditions such as starvation for carbon, nitrogen or essential components like amino- and nucleic acids or by rapamycin treatment (Noda et al. 2002).

**Figure 2: Five sequential steps of autophagy in *S. cerevisiae*.**

After induction of autophagy, an initial sequestering phagophore is assembled at the PAS. Expansion and curvature of the phagophore leads to the engulfment of the cargo (cytoplasm, proteins and organelles) into the double-membraned autophagosome. Fusion of the autophagosomal outer membrane with the vacuolar membrane results in the release of the autophagic body which is surrounded by the inner autophagosomal membrane. Autophagic bodies and the sequestered cargos are digested by hydrolytic enzymes. Finally, the breakdown products are exported into the cytoplasm for reuse. PAS, phagophore assembly site.

Under nutrient-rich conditions the core autophagic protein Atg13 is highly phosphorylated by the target of rapamycin (TOR) kinase (Figure 3). Starvation conditions lead to the inactivation of the TOR kinase and its inability to phosphorylate Atg13. In its unphosphorylated state, Atg13 forms together with the kinase Atg1, Atg11/17, Atg29 and Atg31 the Atg1-kinase complex. This complex is capable of phosphorylating Atg2 and the transmembrane protein Atg9 (Papinski et al. 2014; Papinski and Kraft 2016) (Figure 3A). The proteins Atg1, Atg13, Atg11/17, Atg29 and Atg31 are localized at the phagophore assembly site (PAS) (Suzuki et al. 2001). During selective autophagy Atg17 of the Atg1-kinase complex is exchanged by the scaffolding protein Atg11 (Yorimitsu and Klionsky 2005a).

The nucleation of the autophagosomal membrane requires the phosphorylation of phosphatidylinositol (PtdIns) by complex I consisting of vacuolar protein sorting (Vps)34, Vps15, Atg14, Atg6 and Atg38. Subsequently, phosphorylated Atg2 and Atg9 can then localize at the PAS. Atg2 functions as a connector between Atg9 and the phosphatidylinositol-3-phosphate (PtdIns(3)P) binding protein Atg18 and thereby Atg9 delivers membrane structures to the expanding PAS (Figure 3B) (Reggiori et al. 2005; Araki et al. 2013; Reggiori and Klionsky 2013; Papinski et al. 2014). Recently, the small protein Atg41 was identified, which is suggested to be involved in the autophagosome biogenesis, through interaction with Atg9 (Yao et al. 2015).

During expansion, the Atg12 and Atg8 conjugation systems are necessary to build the double membrane of the autophagosome. Both are ubiquitin (Ub)-like proteins and become conjugated in a Ub-like manner. Atg8 and Atg12 do not share any primary sequence homology with Ub, nevertheless, their crystal structures reveal similarities (Sugawara et al. 2004; Suzuki et al. 2005). Atg8 is initially processed to a glycine-exposed form by the protease Atg4, then activated in an ATP-dependent manner by the E1-like enzyme Atg7, subsequently transferred to the E2-like enzyme Atg3, and finally conjugated to the amino group of phosphatidylethanolamine (PE) (Mizushima et al. 1998; Shintani et al. 1999; Tanida et al. 1999; Ichimura et al. 2000; Ohsumi 2001). Atg12 is also activated by the E1-like enzyme Atg7 but is transferred to the E2-like conjugating enzyme Atg10, which covalently attaches it to a lysine residue of Atg5 (Mizushima et al. 1998; Shintani et al. 1999). The resulting Atg12~Atg5 conjugate then forms a complex with the coiled-coil protein Atg16, and this complex acts as a ubiquitin E3-like ligase for the Atg8-PE conjugation reaction by stimulating the activity of Atg3 and promoting the transfer of Atg8 from Atg3 to the PE substrate (Mizushima et al. 1999; Hanada et al. 2007; Fujita et al. 2008). Both Ub-like conjugates (Atg8-PE and the Atg12~Atg5-Atg16 complex) are localized to the PAS (Suzuki et al. 2001) (Figure 3C). In *S. cerevisiae*, Atg8-PE recruits the Atg12~Atg5-Atg16 complex for membrane localization by recognizing a non-canonical Atg8-interacting motif (AIM) in Atg12 (Kaufmann et al. 2014). In the growing phagophore, the Atg12~Atg5-Atg16 complex localizes exclusively to the convex side of the growing cup-shaped phagophores, while Atg8-PE localizes at both sides of the phagophore (Mizushima et al. 2003; Suzuki et al. 2013).

**Figure 3: Proteins involved in autophagy in the yeast *S. cerevisiae*.**

(A) Induction of autophagy under nutrient-starvation conditions followed by the formation of the Atg1-kinase complex. (B) Vesicle nucleation mediated by the phosphorylation of phosphatidylinositol at the PAS. (C) Expansion of the phagophore by conjugation of Atg8-PE to the PAS via the Atg8 and Atg12 conjugation pathways. (D) Fusion of the outer membrane of the autophagosome with the vacuolar membrane releasing the autophagic body and breakdown within the vacuole by hydrolases. TOR, target of rapamycin; PAS, phagophore assembly site; PE, phosphatidylethanolamine; PtdIns, phosphatidylinositol; PtdIns(3)P, phosphatidylinositol-3-phosphate; PI3, phosphoinositide 3; P, phosphorylation.

On the convex membrane site of the phagophores, Atg16 promotes oligomerization of the Atg12~Atg5-Atg16 complex and assembles with Atg8-PE into a two-dimensional meshwork (Kaufmann et al. 2014). Cytosol and organelles are then surrounded by this membrane forming the autophagosome, which is transported to the vacuole. The outer membrane of the

autophagosome is able to fuse with the vacuolar membrane and releases a single-membraned autophagic body into the lumen of the vacuole. The vacuolar lipase Atg15 degrades the inner autophagosomal membrane and the content of the autophagic body is digested by hydrolytic vacuolar enzymes (Epple et al. 2001) (Figure 3D). The permease Atg22 is an integral vacuolar membrane protein and contributes to the release of vacuolar degradation products into the cytoplasm (Yang et al. 2006). The recycled components can be reused for anabolic processes in the cell.

### 1.3 Selective autophagy processes mediated by cargo receptors

In addition to non-selective autophagy, the degradation of cytoplasm and organelles in a random manner, selective autophagy processes deliver specific cargos to the lysosome/vacuole and can be subdivided into mitophagy (for mitochondria), pexophagy (for peroxisomes), ribophagy (for ribosomes), reticulophagy (for the endoplasmic reticulum, ER), nucleophagy (for the nucleus) and aggrephagy (for aggregates) and the cytoplasm-to-vacuole targeting (Cvt)-pathway exclusively present in *S. cerevisiae* (Khalfan and Klionsky 2002; Kim et al. 2007; Meijer et al. 2007b; Kraft et al. 2008; He and Klionsky 2009; Kanki and Klionsky 2009; Kraft et al. 2010; Lynch-Day and Klionsky 2010; Mochida et al. 2015; Nakatogawa and Mochida 2015) (Figure 4). The Cvt pathway mediates the transport of hydrolytic enzymes such as amino peptidase 1 (Ape1) and  $\alpha$ -mannosidase (Ams1) from the cytoplasm under non-starvation conditions.

The detailed mechanisms of these selective pathways remain to be characterized but some common principles are arising (Figure 4). It is known that a receptor recognizes and binds a specific cargo to direct it to the autophagosomes. During this process the core autophagy machinery is required for all the selective types of autophagy. Often, ubiquitin acts as a signaling molecule for selective autophagy (Kraft et al. 2010).

In yeast but not in filamentous fungi, during nutrient-rich conditions, the Cvt pathway uses the receptor Atg19 and the related protein Atg34 for the selective transport of hydrolytic enzymes from the cytosol to the vacuole (Figure 4B). Atg19 binds directly to its cargo Ape1 or Ams1, whereas Atg34 binds only Ams1, to form the so called Cvt complex (Watanabe et al. 2010). Subsequently, the receptors mediate the recruitment of the Cvt complex to the PAS via interaction with Atg11 (Zaffagnini and Martens 2016). The cargo receptors Atg19 and Atg34 are able to bind to Atg8 via a conserved LC3-interacting region (LIR), also known as AIM, to mediate the engulfment of the complex by vesicle formation (Pankiv et al. 2007; Ichimura et al. 2008). The LIR motif allows the interaction with LC3-family proteins including the

mammalian homolog of the yeast Atg8 protein and consists of the consensus sequence X<sub>3</sub>-X<sub>2</sub>-X<sub>1</sub>-(W/Y/F<sub>0</sub>)-X<sub>1</sub>-X<sub>2</sub>-(L/I/V<sub>3</sub>)-X<sub>4</sub>-X<sub>5</sub> (Alemu et al. 2012; Suzuki et al. 2014). The scaffold protein Atg11 is required for the localization of the Cvt vesicle to the PAS (Khalfan and Klionsky 2002; Shintani et al. 2002; Yorimitsu and Klionsky 2005a; Watanabe et al. 2010; Sawa-Makarska et al. 2014). Phosphorylation of the cargo receptors promote their interaction with Atg11. The kinase Hrr25 (HO and radiation repair) was identified to phosphorylate Atg19 whereas an unknown kinase exists for Atg34 (Pfaffenwimmer et al. 2014; Tanaka et al. 2014). Mitophagy represents another selective autophagy process in *S. cerevisiae* and higher eukaryotes, which is important for the cell to remove damaged or harmful mitochondria. In yeast, a protein of the outer mitochondrial membrane, Atg32, was identified as a receptor for mitophagy (Kanki and Klionsky 2009; Okamoto et al. 2009). After phosphorylation by the casein kinase 2 (CK2) Atg32 is able to interact with Atg11 and Atg8. Interaction of Atg32 and Atg8 is mediated by the LIR motif (Farre et al. 2013; Kanki et al. 2013; MacVicar 2013) (Figure 4C).

The selective degradation of peroxisomes via autophagy uses Atg30 in *P. pastoris* or Atg36 in *S. cerevisiae* as cargo receptors. Both receptors are phosphorylated by kinases and interact with peroxisomal membrane proteins Pex3 and/or Pex14 (Farre et al. 2008; Farre et al. 2013; Tanaka et al. 2014) (Figure 4C). Upon phosphorylation they interact with core autophagy machinery components Atg11 and Atg17 (Farre et al. 2013; Tanaka et al. 2014). The cargo receptors Atg30 and Atg36 bind directly to the Atg8 protein in a LIR-dependent manner (Farre et al. 2008; Motley et al. 2012). Recently, the acyl-CoA binding protein Atg37 was identified as a new component of the pexophagy process in *P. pastoris*. Atg37 is an integral peroxisomal membrane protein that binds Pex3 and Atg30, but not Pex14 or Atg8. The role of Atg37 is to facilitate the Atg30-Atg11 interaction and therefore to regulate the dynamic of this process (Nazarko et al. 2014; Burnett et al. 2015).

Aggrephagy uses the molecular tag ubiquitin for the identification of a protein aggregate for autophagic degradation (Figure 4D).

**Figure 4: Cargo recognition during selective autophagy.**

(A) General scheme of cargo recognition during selective autophagy. A receptor is able to bind the substrate (organelles, proteins, microbes) in some cases labeled with ubiquitin (Ub) and interacts with Atg8 family proteins of the PAS (Johansen and Lamark 2011). (B) In *S. cerevisiae*, the Cvt pathway transports the hydrolytic enzymes Ape1 and Ams1 to the vacuole. At the PAS, the cargo receptors Atg19 and Atg34 are phosphorylated. Phosphorylated Atg19 binds Ape1 or Ams1 and phosphorylated Atg34 binds Ams1. Subsequently, both receptors can interact with Atg11 and Atg8 (Zaffagnini and Martens 2016). (C) Organelle specific autophagy processes in yeast. During mitophagy, Atg11 connects the selective receptor Atg32, a mitochondrial outer membrane protein, to Atg8 at the PAS. During this process Atg32 gets phosphorylated (MacVicar 2013). The selective autophagy degradation of peroxisomes uses Atg30 in *P. pastoris* and Atg36 in *S. cerevisiae*, which are localized at the peroxisomal membrane, and interact with Pex3 and/or Pex14. The cargo receptors are phosphorylated and upon induction they interact with core autophagy machinery components Atg11 and Atg17 (Farre et al. 2008; Motley et al. 2012). The cargo receptors bind directly to the Atg8 protein which is localized to the PAS. Additionally, Atg37 is an integral peroxisomal membrane protein which can bind Pex3 and Atg30 to facilitate the Atg30/36-Atg11 interaction (Nazarko 2014). (D) In mammals, ubiquitinated proteins bind to the cargo receptors p62 and/or Nbr1. Both receptors are connected to Atg8 family proteins in the autophagosomal membrane. This process is called aggrephagy (Stolz et al. 2014). PAS, phagophore assembly site; P, phosphorylation.

It provides an alternative to the proteasomal degradation pathway and allows the degradation of toxic, aggregated or long-living proteins (Kraft et al. 2010). In mammals but not in yeast, NBR1 (neighbour of BRCA1) and p62/SQSTM1 (sequestosome 1) are described as cargo receptors for the degradation of ubiquitinated substrates. Both can interact with ATG8 via the

LIR motif, which is an essential structural component of the autophagosomal membrane, and with ubiquitin via a ubiquitin-associated (UBA) domain (Pankiv et al. 2007; Kirkin et al. 2009; Stolz et al. 2014).

Despite the fact that mammalian proteins p62 and NBR1 have a similar domain organization, not all domains present in NBR1 are present in p62 (Deosaran et al. 2013). In eukaryotes, NBR1 is highly conserved while p62 is only found in metazoans. Homologs of NBR1 have been described in plants and mammals, but not in *S. cerevisiae*. In plants, the homolog of NBR1 has been shown to interact with the homolog of ATG8 and is involved in the selective autophagy degradation of ubiquitinated proteins (Svenning et al. 2011; Zhou et al. 2013). The mammalian NBR1 protein is characterized by an N-terminal Phox and Bem1 (PB1) domain responsible for heterodimerization with p62, followed by two coiled-coil (CC) domains for homo-dimerization, different ZZ-type zinc-finger (ZZ) domains and a unique NBR1 box characterized by four tryptophan (W) (FW) residues with unknown function. A C-terminal UBA domain is capable of binding ubiquitinated proteins (Hofmann and Bucher 1996). In close proximity to the UBA domain a 22 amino acid Juxta UBA (J) domain was identified in metazoan NBR1 homologs. This domain forms a membrane-interacting amphipathic  $\alpha$ -helix (Mardakheh et al. 2010). The NBR1, CC and J domains are lacking in the p62 protein (Kirkin et al. 2009; Kraft et al. 2010; Svenning et al. 2011) (Figure 5).

**Figure 5: Domain architecture of the *Homo sapiens* NBR1 and p62.**

The NBR1 protein and its counterpart p62 are characterized by common domains like PB1, Phox and Bem1 domain; ZZ, ZZ-type zinc-finger domain; LIR, LC3-interacting region; UBA, ubiquitin-associated domain. NBR1 contains additionally CC, coiled-coil domain; the typical NBR1-domain and N-terminal of the UBA domain in close proximity the JUBA, juxta-ubiquitin-associated domain. Functional domains are represented as colored boxes, with similar colors indicated similar domains. Amino-acid scale bar is indicated.

In *S. cerevisiae*, the Cvt receptor Atg19 is suggested to be a functional equivalent to NBR1 (Kraft et al. 2010). Fission yeast *Schizosaccharomyces pombe* has neither the Cvt pathway nor its receptor Atg19 but expresses a NBR1-like protein called Nbr1. This protein functions as a receptor for delivering the hydrolytic enzymes Ape2 and Lap2 (lamina-associated polypeptide 2) to the vacuole via an unconventional autophagy-independent mechanism (Liu et al. 2015; Mizushima 2015). Interestingly, the homolog in fission yeast lacks the PB1 domain, the LIR motif, CC and UBA domains but it possesses a similar NBR1 box.

With the exception of zygomycetes, NBR1 homologs of all fungi lack the UBA domain (Kraft et al. 2010). So far, the function of NBR1 homologs in filamentous fungi is unknown.

In contrast to this, it is known that in mammals, beside its function in aggrephagy, NBR1 is involved in pexophagy (Deosaran et al. 2013).

#### **1.4 Pexophagy, the autophagic degradation of peroxisomes**

Peroxisomes are abundant single membrane-bound organelles in eukaryotic cells and have various physiological functions based on their role in diverse metabolic pathways. The primary role of fungal peroxisomes is the  $\beta$ -oxidation of fatty acids and detoxification of reactive oxygen species (ROS). Fungal mutants lacking peroxisomes fail to grow on media containing fatty acids as sole carbon source (Erdmann et al. 1989; Hynes et al. 2008). In filamentous fungi, peroxisomes are also responsible for the biosynthesis of biotin, the formation of secondary metabolites including the biosynthesis of penicillins, polyketides, terpenes and paxilline (Maggio-Hall et al. 2005; Saikia and Scott 2009; Imazaki et al. 2010; Bartoszewska et al. 2011; Tanabe et al. 2011). Moreover, peroxisomes are involved in plant pathogenicity of fungi (Kimura et al. 2001; Asakura et al. 2006), sexual development and growth (Bonnet et al. 2006; Managadze et al. 2007; Peraza-Reyes et al. 2008). The biogenesis and proteostasis of peroxisomes is essential to adapt to environmental changes and to control metabolic events in the cell. To maintain a healthy cellular peroxisome population, dysfunctional or useless peroxisomes are degraded by pexophagy. This turnover process may occur randomly (bulk sequestration of cytoplasm portions) or selectively. In filamentous ascomycetes, peroxisomes arise predominantly at the hyphal tips and their biogenesis is controlled by *pex* genes, which encode proteins called peroxins (Distel et al. 1996; Kiel et al. 2006). Over 30 peroxins have been identified in fungal genomes. Most of them are evolutionarily conserved but some are specific for filamentous fungi (Kiel et al. 2006; Managadze et al. 2007; Peraza-Reyes et al. 2011; Li et al. 2016). Peroxins are involved in the *de novo* formation of peroxisomes from the endoplasmatic reticulum, in their division and the import of folded proteins into the peroxisomal matrix. Two major classes of peroxisomal targeting signals (PTS) are present in peroxisomal matrix proteins. The PTS1 sequence comprises three C-terminal amino acids characterized by the amino-acid sequence S/A-R/K-L. Other peroxisomal matrix proteins have a PTS2 sequence close to the N-terminus with the consensus sequence R-L-X5-H-L (where X represents any amino acid) (Gould et al. 1989; Swinkels et al. 1991; Petriv et al. 2004; Brocard and Hartig 2006). In *S. cerevisiae*, two types of cytosolic receptor proteins have been identified for the

import of the two classes of matrix proteins. Each recognizes one of the PTSs, PEX5 and PEX9 PTS1-matrix proteins and the PTS2 receptor complex PEX7 together with its co-receptors PEX18 and PEX21 PTS2 matrix proteins (Kiel et al. 2006; Kiel and van der Klei 2009; Effelsberg et al. 2016). The cargo-receptor complex is then transported to an import pore present in the peroxisomal membrane. After docking, the translocation of the cargo-receptor complex across the peroxisomal membrane occurs through distinct PTS1 and PTS2 pores (Montilla-Martinez et al. 2015). The pore for PTS1 proteins consists of the PTS1 receptor PEX5 and the protein PEX14 or PEX13, whereas the PTS2 pore is characterized by the three peroxins PEX14, PEX17 and PEX18 (Managadze et al. 2007; Opalinski et al. 2010). The translocation is followed by the dissociation of the cargo receptor and recycling of the receptor to the cytosol for further import cycles (Erdmann and Schliebs 2005).

The key point in pexophagy, as in other selective autophagy pathways, is the mechanism by which the core autophagy machinery is directed to degrade primarily peroxisomes. Until now, four pexophagy receptors have been identified: Atg30 in *P. pastoris* and related yeasts (Farre et al. 2008; Nazarko 2014), Atg36 in *S. cerevisiae* and related yeasts (Motley et al. 2012) and NBR1 and/or p62 for mammalian cells (Kim et al. 2008; Deosaran et al. 2013). The receptors display a modular composition of binding domains and motifs for cargo delivery to the site of developing and engulfing autophagosomes. Common for the most of these receptors is the presence of a LIR motif and a UBA domain (Behrends and Fulda 2012).

In mammals, pexophagy can be induced by expression of ubiquitinated peroxisomal membrane proteins and it has been demonstrated that p62 together with LC3-II (ATG8) is required for the degradation of ubiquitin-decorated peroxisomes by interacting with an unknown peroxisomal protein (Kim et al. 2008). However, Deosaran et al. (2013) showed that pexophagy is also induced by overexpression of NBR1, which promotes peroxisome clustering around NBR1 oligomers and autophagic peroxisome degradation. The J and the UBA domains of mammalian NBR1 are required for pexophagy. Moreover, ubiquitinated PEX5 and overexpression of PEX3 target NBR1 to clustered peroxisomes (Deosaran et al. 2013; Yamashita et al. 2014).

In *P. pastoris*, the acyl-CoA binding protein Atg37 is an integral peroxisomal membrane protein that binds, similar to the receptor Atg30, Pex3 in the peroxisomal membrane (Nazarko et al. 2014; Burnett et al. 2015). Atg30 can additionally bind the peroxisomal membrane protein Pex14 (Farre et al. 2008). Further, Atg37 interacts with Atg30 to facilitate the engagement of the scaffold protein Atg11 (Nazarko et al. 2014). To bind both Atg11 and the phagophore protein Atg8, Atg30 has to be phosphorylated by a yet unknown kinase (Farre et al. 2008; Nazarko et al. 2014) (Figure 4C). The *S. cerevisiae* Atg36 receptor is recruited to peroxisomes

also by Pex3. It is phosphorylated by the kinase Hrr25 and interacts with the scaffold protein Atg11 (Tanaka et al. 2014). Atg36 remains to be associated with Atg8 for autophagosomes formation and like other receptors for selective autophagy it is broken down together with its substrate in the vacuole (Motley et al. 2012).

So far, it is unknown how pexophagy is regulated in filamentous fungi. In addition to peroxisomes some filamentous fungi possess a peroxisomal organelle called Woronin body, which is responsible to seal damaged hyphae by plugging the septal pore (Markham 1994). Woronin bodies originate from peroxisomes (Jedd and Chua 2000).

Filamentous fungi grow via elongation of the hyphal tip and form hyphae in which many cellular compartments are interconnected through septal pores that allow the passage of cytoplasm and organelles between neighboring septa (Markham 1994; Lew 2005; Ng et al. 2009). This mode of cellular organization is a benefit and risk because the cell is able to respond to environmental changes and to undergo developmental processes but in case of hyphal wounding cytoplasmic loss takes place. When hyphae lyse, their septal pores need to be sealed to prevent complete cytoplasm leakage and cell death. This function is exclusively undertaken by an organelle known as Woronin body (Woronin 1864) and is uniquely present in Pezizomycotina (Maruyama et al. 2005; Jedd 2011). The main component of Woronin bodies is the protein HEX1, firstly identified in *Neurospora crassa* (Jedd and Chua 2000). The *N. crassa* HEX1 protein, with a predicted molecular mass of 19.13 kDa, has the PTS1 SRL motif as a peroxisomal targeting signal (Jedd and Chua 2000). Upon import of HEX1 into peroxisomes self-assembly of HEX1 takes place and Woronin bodies proliferated by growth and division. The Woronin-body sorting complex (WSC) recruits HEX1 to the matrix face of the peroxisomal membrane (Liu et al. 2008) and promotes the budding from peroxisomes which involves the function of PEX11. A specific protein leashin (LAH) tethers the Woronin body to septa (Ng et al. 2009). Deletion of the *hex1* gene in *N. crassa* results in the disappearance of Woronin bodies and is associated with severe cytoplasmic bleeding upon hyphal lysis (Jedd and Chua 2000). Degradation of Woronin bodies by autophagy has not yet been analyzed in filamentous fungi.

Beside peroxisomes, another organelle that has been described to be selectively degraded by autophagy are ribosomes.

## 1.5 Ribophagy, the autophagic degradation of ribosomes

All cellular proteins are synthesized by ribosomes, whose biogenesis is a complex multi-step and the most energy consuming cellular process. The biogenesis and degradation of ribosomes is therefore tightly controlled upon nutrient limitations (Warner 1999). A study has shown that the selective autophagy of surplus ribosomes balances the ribosome biogenesis (Kraft et al. 2008). In *S. cerevisiae*, it has been demonstrated that ribosomes are regulated in their number by ribophagy. Under nutrient-starvation conditions ribosomal proteins are degraded faster than other cytoplasmic proteins. It was demonstrated that the transport of ribosomes to the vacuole relies on core autophagy components such as Atg1 and Atg7. A mutant screening in *S. cerevisiae* focusing on defects in ribosome turnover upon starvation, identified the ubiquitin-specific processing protease 3 (Ubp3) and its cofactor brefeldin A sensitivity 5 (Bre5). Together with the cell division cycle 48 (Cdc48) AAA-ATPase and the ubiquitin binding protein ubiquitin fusion degradation 3 (Ufd3) they are required for the selective degradation of the large 60S ribosomal subunit, but not for the small 40S subunit (Kraft et al. 2008; Ossareh-Nazari et al. 2010). When Ubp3 is associated with its cofactor Bre5 it removes ubiquitin from damaged or misfolded proteins (Brew and Huffaker 2002) including the large ribosomal protein Rpl25. This deubiquitination of Rpl25 is required to trigger the uptake of the large ribosomal subunit by the autophagosome, followed by degradation of ribosomal proteins in the vacuole. Under nutrient-rich conditions Rpl25 is ubiquitinated by the E3 ligase Ltn1 (listerin E3 ubiquitin protein ligase 1). Ltn1 targets the lysine 74 of the Rpl25 and thereby protecting the 60S ribosomal subunit against ribophagy in a Ubp3-antagonistic manner (Ossareh-Nazari et al. 2014) (Figure 6).

**Figure 6: Model for the role of Ltn1 and Ubp3/Bre5 in starvation-induced ribophagy in *S. cerevisiae* (modified after Ossareh-Nazari et al. (2014)).**

Under nutrient-rich conditions Ltn1 ubiquitinates Rpl25 from the large ribosomal subunit. Under starvation conditions the level of Ltn1 decreases and the Ubp3/Bre5 complex acts in the deubiquitination of Rpl25, which is then targeted by a still unknown autophagy cargo receptor. Subsequently, the large ribosomal subunit is transported to the vacuole and the proteins are degraded by hydrolytic enzymes. 60S, 60S ribosomal subunit; R describes an unidentified cargo receptor; PAS, phagophore assembly site; Ub, ubiquitin.

Under starvation conditions the levels of Ltn1 decrease and the Ubp3/Bre5 complex acts in the deubiquitination of Rpl25, which is then targeted to selective autophagy by a still unknown receptor (Figure 6). Recently it was reported that ribophagy requires in addition the autophagy scaffold protein Atg11 and is upregulated by the protein kinase Rim15 (Waliullah et al. 2016). The selectivity “receptor” for ribosome-autophagosome assembly is unknown and it remains to be investigated in more detail how ribosomes are subjected to autophagy or how they are recognized by the receptor and how ribophagy is regulated in eukaryotes.

## **1.6 *Sordaria macrospora*: a model organism to study fruiting-body development**

The ascomycete *Sordaria macrospora*, which is a close relative of *N. crassa*, is a model organism to study fruiting-body development. In recent years it turned out that *S. macrospora* is also well suitable to analyze the involvement of autophagy on complex developmental processes (Teichert et al. 2014). The filamentous ascomycete *S. macrospora* belongs to the order *Sordariales*. Under natural conditions, *S. macrospora* is a coprophilous fungus and grows on herbivore dung. It is self-fertile (homothallic) and lacks an asexual life cycle, meaning it solely undergoes a sexual life cycle without the need of a mating partner. In contrast to *N. crassa*, *S. macrospora* produces no asexual spores (Esser and Straub 1958; Pöggeler et al. 1997; Lord and Read 2011). Thus, mutations can be directly tested on their influence on fruiting-body formation (Teichert et al. 2014). The life cycle of *S. macrospora* is illustrated in Figure 7. The formation of multicellular fruiting bodies is an essential step in sexual reproduction of *S. macrospora* and involves highly controlled cellular differentiation programs (Pöggeler et al. 2006).

*S. macrospora* is a haplont with a genome of seven chromosomes ranging in size from 3.7-7.5 Mb (Pöggeler et al. 2000). It is suitable for genetic analysis because the genome of 39.8 Mb is completely sequenced (Nowrousian et al. 2010).

Another advantage of *S. macrospora* is the formation of large ascospores (31x18 µm) (Walkey and Harvey 1966), which allow classical genetic experiments and the isolation of homokaryotic mutants after mutagenesis (Esser and Straub 1958; Teichert et al. 2014). Additional benefits of *S. macrospora* are its short life cycle of seven days and the easy handling and cultivation under laboratory conditions. *S. macrospora* is closely related to the heterothallic ascomycete *N. crassa* as evidenced by nucleic-acid identity of 90 % within coding regions of orthologous genes (Nowrousian et al. 2010).

The *S. macrospora* life cycle starts with a germinating ascospore and the formation of a two dimensional vegetative mycelium. The development of asci begins with the formation of female gametangia called ascogonia. Finally, the differentiation to fruiting-body precursors occurs which are called protoperithecia and later develops to mature fruiting bodies (perithecia). Karyogamy, meiosis, and postmeiotic mitosis occur in the perithecium and each perithecium harbors approximately 200 asci with eight linearly ordered ascospores. These are discharged by an increased turgor pressure at day seven to eight through an apical pore (ostiole) at the neck of the fruiting body (Engh et al. 2010; Lord and Read 2011) (Figure 7).

**Figure 7: Life cycle of the homothallic ascomycete *S. macrospora* (Kück et al. 2009).**

The cycle starts with the germination of an ascospore. After approximately three d the female gametangia (ascogonium) starts to develop. The protoperithecium is the fruiting-body precursor and is formed by enveloping the ascogonium with sterile hyphae. After 4-5 d the young and round fruiting body develops into a pear-shaped mature fruiting body (perithecium) with approximately 200 asci each containing eight linearly ordered ascospores inside. The cycle ends with the discharge of the ascospores after approximately seven days.

All in all, the ascomycete *S. macrospora* is a good model system for higher eukaryotes to analyze multicellular development, meiosis and differentiation processes and also conserved processes like autophagy (Engh et al. 2010; Nowrousian et al. 2010; Teichert et al. 2014).

## 1.7 The autophagy process in *S. macrospora*

The process of autophagy has been intensively investigated in yeast. However, not much is known in filamentous fungi. A BLASTP search in *S. macrospora* revealed 16 of the 17 core ATG proteins, as well as VPS34 and VPS15, and nine of the other 24 ATG proteins involved in induction and selective autophagy are conserved (Meijer et al. 2007a; Avin-Wittenberg et al. 2012; Voigt and Pöggeler 2013b) (Table 1).

**Table 1: Conservation of *atg* genes in *S. macrospora* compared to yeasts.**

41 *atg* genes have been identified in the yeasts *S. cerevisiae*, *P. pastoris* (\*) and *Pichia angusta* (#). By BLASTP search in *S. macrospora*, 16 of the 17 core ATG proteins and nine of the 24 proteins involved in the induction of autophagy and selective autophagy are conserved when compared with yeast homologs. Conserved proteins in *S. macrospora* are indicated with the SMAC number (e value,  $<e^{-10}$ ); similar proteins are underlined (e value,  $>e^{-10}$ ); not found, means no significant homolog in *S. macrospora*.

In the filamentous ascomycete *S. macrospora* previous studies have shown that autophagy is required for vegetative growth, the development of fruiting bodies and viability (Nolting et al.

2009; Voigt et al. 2013; Voigt and Pöggeler 2013b; Voigt and Pöggeler 2013a; Teichert et al. 2014; Voigt et al. 2014).

In *S. macrospora*, the conservation of the core *atg* genes *Smatg8* and *Smatg4* was verified by the heterologous expression of SmATG8 and SmATG4 in *S. cerevisiae atg8* and *atg4* deletion strain. Deletion of *Smatg8* and *Smatg4* leads to a lower germination efficiency, as well as to a sterile phenotype, underlining the importance of these proteins for fruiting-body development (Voigt and Pöggeler 2013a). These two proteins seem to be important for non-selective pexophagy as well, since the study from Voigt and Pöggeler (2013a) has shown that pexophagy is abolished in *Smatg8* and *Smatg4* deletion mutants.

Additionally, the E1-like enzyme SmATG7 was shown to be required for the viability of *S. macrospora*. It was not possible to generate a homokaryotic  $\Delta$ *Smatg7* mutant (Nolting et al. 2009).

Similarly, deletion of the vacuolar protein sorting genes *Smvps34* and *Smvps15* prevented the isolation of homokaryotic knockout strains, showing that they are also required for viability of *S. macrospora*. In *S. cerevisiae*, VPS34 is the core protein of the complex I (ATG6, ATG14, VPS15 and VPS34), and complex II (ATG6, VPS38, VPS15 and VPS34), and important for protein sorting in the vacuole. Moreover, the PtdIns(3)P activity of VPS34 is required for G-protein signaling and in the Tor nutrient-sensing (Voigt et al. 2014). VPS15 is the regulatory subunit and membrane targeting unit of VPS34 (Yan and Backer 2007).

To get a better understanding how autophagy is regulated, the function of the bZIP transcription factor SmJLB1, a homolog of the *Podospora anserina* basic zipper-type transcription factor I induced during incompatibility 4 (IDI4) and the *Aspergillus nidulans* transcription factor jun-like bZIP A (JlbA), was analyzed. Deletion of *Smjlb1* impaired vegetative growth and fruiting-body development in *S. macrospora*. SmJLB1 acts as a repressor on gene expression of *Smatg8* and *Smatg4*. SmJLB1 is localized to the cytoplasm and to nuclei (Voigt et al. 2013).

In conclusion, conserved core components of the autophagic machinery are involved in developmental processes and viability.

## 1.8 Aims of this thesis

Autophagy is a major cellular degradation pathway conserved in eukaryotes which is mainly investigated in the baker's yeast *S. cerevisiae*. It permits the cells to eliminate unwanted proteins or organelles and to recycle components for reuse within a double-membraned autophagosome and vacuole. It has a great variety of physiological and pathophysiological roles in eukaryotic cells. In yeast, 41 *atg* genes exist and the ubiquitin-like gene *Smatg12* represents one of the conserved core autophagy genes. Up to now, its function was not analyzed in filamentous fungi. The deletion mutant of  $\Delta$ *Smatg12* will be analyzed regarding its function in vegetative growth and sexual development. In case of phenotypical alterations it should be rescued in complementation experiments using an *egfp-Smatg12* fusion construct. The complemented strain will be used for *in vivo* localization studies of EGFP-SmATG12 in *S. macrospora*. Furthermore, the functional conservation of SmATG12 and its yeast counterpart will be analyzed by a yeast complementation assay with the *Smatg12* cDNA expressed under the control of a *MET25* promoter in an *S. cerevisiae* *atg12* $\Delta$  null mutant. Rescue of autophagy in the *S. cerevisiae* *atg12* $\Delta$  mutant will be monitored using an aminopeptidase I (Ape1) maturation assay based on the autophagy-dependent maturation of the precursor proaminopetidase I (prApe1) to the mature enzyme (mApe1).

Selective autophagy is characterized by cargo receptor proteins, which are able to bind a specific cargo including organelles, proteins or microbes for their autophagic degradation. In addition to SmATG12, SmATG8 represents another core autophagy protein, which is necessary for autophagosome formation (Voigt and Pöggeler 2013a).

GFP-Trap analysis followed by liquid chromatography mass spectrometry (LC/MS) using SmATG8 as bait identified SmNBR1 as putative interaction partner of SmATG8 (Voigt 2012). SmNBR1 is a putative homolog of the human autophagy cargo receptor NBR1.

To determine whether selective autophagy is necessary for vegetative growth and fruiting-body development in *S. macrospora*, the function of the putative cargo receptor SmNBR1 should be analyzed. For this, a  $\Delta$ *Smnbr1* mutant strain as well as a complementation strain should be constructed and phenotypically analyzed under stress-inducing conditions. NBR1 proteins display a conserved domain architecture. Therefore, a complementation of the  $\Delta$ *Smnbr1* mutant with the *H. sapiens* NBR1 homolog is planned. In mammals and plants an interaction between ATG8 and NBR1 has been described (Johansen and Lamark 2011; Svenning et al. 2011). For this reason, the proteins SmATG8 and SmNBR1 should be co-localized in *S. macrospora* by fluorescence microscopy and their interaction should be verified by Bimolecular fluorescence

complementation experiments (BiFC), yeast-two hybrid assays and Co-immunoprecipitation experiments (Co-IP).

Mutations and truncated constructs of SmNBR1 should be constructed and tested for their complementation ability of  $\Delta$ Smnbr1 and should be localized regarding to the formation of autophagosomes and their vacuolar localization.

Since it is known that NBR1 is involved in the turnover of endogenous peroxisomes in mammals (Deosaran et al. 2013), the function of SmNBR1 in the autophagic degradation of peroxisomes, called pexophagy, should be investigated. For this, the localization of peroxisomal proteins will be analyzed in  $\Delta$ Smnbr1 and the autophagy-defective mutant  $\Delta$ Smatg8 and compared to the localization observed in wild type. With regard to the function of peroxisomes, including the  $\beta$ -oxidation of fatty acids and detoxification of reactive oxygen species, the growth on media containing long-chain fatty acids as sole carbon source will be tested in the  $\Delta$ Smnbr1 strain as well as the growth on media containing H<sub>2</sub>O<sub>2</sub>. Woronin bodies are unique organelles present in Pezizomycotina (Maruyama et al. 2005; Jedd 2011), which arise from peroxisomes. Therefore the function of Woronin bodies will also be analyzed in the  $\Delta$ Smnbr1 mutant strain. Additionally, putative cargos of SmNBR1 should be identified by GFP-Trap and LC/MS analysis using SmNBR1 as bait.

Ribophagy describes the selective autophagic degradation of ribosomes. Since the selectivity receptor for ribophagy is unknown in yeast and in higher eukaryotes it remains to be investigated in more detail how ribosomes are subjected to autophagy. It is unknown how intact ribosomal subunits are recognized by the receptor and how ribophagy is regulated in eukaryotes. Therefore, ribosomal proteins of either the large 60S ribosomal subunit or a small 40S ribosomal subunit protein should be analyzed in the  $\Delta$ Smnbr1 strain. The EGFP-labeled large and small ribosomal proteins will be localized to follow their degradation in the vacuole. Furthermore, the proteins also should be studied by quantitative Western-blot experiments.

pRS-YC	C-terminal part of <i>eyfp</i> under control of <i>gpd</i> promoter, <i>URA3</i> , <i>amp<sup>R</sup></i> , <i>nat<sup>R</sup></i>	This study
pRS-YN	N-terminal part of <i>eyfp</i> under control of <i>gpd</i> promoter <i>URA3</i> , <i>amp<sup>R</sup></i> , <i>hyg<sup>R</sup></i>	This study
pOTB7+cDNA	<i>cm<sup>R</sup></i> , <i>Hsnbr1</i> cDNA	transOMIC technologies™, BC009808

### localization studies and knockouts

pSmnbr1-KO	1050 bp of the 5'-flanking region and 785 bp of 3'-flanking region of <i>Smnbr1</i> interrupted by the <i>hph</i> -cassette in pRS426	This study
pSmatg12-KO	1058 bp of the 5'-flanking region and 700 bp of 3'-flanking region of <i>Smatg12</i> interrupted by the <i>hph</i> -cassette in pRS426	(Werner et al. 2016)
pSmnbr1-egfp	991 bp of the 5'-flanking region and 2681 bp of the ORF of <i>Smnbr1</i> without stop codon, <i>egfp</i> and <i>trpC</i> terminator (1506 bp) in pRSnat	This study
pSmnbr1-Dsred	991 bp of the 5'-flanking region and 2681 bp of the ORF of <i>Smnbr1</i> without stop codon, <i>Dsred</i> and <i>trpC</i> terminator (1466 bp) in pRShyg or pRSnat	This study
pccg1-Smnbr1-egfp	921 bp of <i>ccg1</i> promoter region and 2681 bp of <i>Smnbr1</i> ORF without stop codon, <i>egfp</i> and <i>trpC</i> terminator (1506 bp) in pRSnat	This study
pSmnbr1-1-418-egfp	991 bp of the 5'-flanking region and 1346 bp ORF of <i>Smnbr1</i> without stop codon, <i>egfp</i> and <i>trpC</i> terminator (1506 bp) in pRSnat	This study

## Materials and Methods

---

pSmnbr1-419-863-egfp	991 bp of the 5'-flanking region and 1332 bp ORF of <i>Smnbr1</i> without stop codon, <i>egfp</i> and <i>trpC</i> terminator (1506 bp) in pRSnat	This study
pSmnbr1-1-843-egfp	991 bp of the 5'-flanking region and 2621 bp of the ORF of <i>Smnbr1</i> without stop codon, <i>egfp</i> and <i>trpC</i> terminator (1506 bp) in pRSnat	This study
pSmnbr1-Y <sup>847</sup> A L <sup>850</sup> A-egfp	991 bp of the 5'-flanking region and 2681 bp of the ORF of <i>Smnbr1</i> inserted mutations in Y <sup>847</sup> A L <sup>850</sup> A without stop codon, <i>egfp</i> and <i>trpC</i> terminator (1506 bp) in pRSnat	This study
pSmnbr1-T <sup>843</sup> A-egfp	991 bp of the 5'-flanking region and 2681 bp of the ORF of <i>Smnbr1</i> inserted mutations in T <sup>843</sup> A without stop codon, <i>egfp</i> and <i>trpC</i> terminator (1506 bp) in pRSnat	This study
pSmnbr1-T <sup>843</sup> A Y <sup>847</sup> A L <sup>850</sup> A-egfp	991 bp of the 5'-flanking region and 2681 bp of the ORF of <i>Smnbr1</i> inserted mutations in T <sup>843</sup> A Y <sup>847</sup> A L <sup>850</sup> A without stop codon, <i>egfp</i> and <i>trpC</i> terminator (1506 bp) in pRSnat	This study
pSmnbr1-S <sup>793</sup> A S <sup>804</sup> A S <sup>808</sup> A-egfp	991 bp of the 5'-flanking region and 2681 bp of the ORF of <i>Smnbr1</i> inserted mutations in S <sup>793</sup> A S <sup>804</sup> A S <sup>808</sup> A without stop codon, <i>egfp</i> and <i>trpC</i> terminator (1506 bp) in pRSnat	This study
pSmnbr1-YC	706 bp <i>gpd</i> promoter and 2681 bp of <i>Smnbr1</i> ORF without stop codon, C-terminal part of <i>yfp</i> (306 bp), <i>trpC</i> terminator (765 bp) in pRS-YC	This study
pYN-Smatg8	706 bp <i>gpd</i> promoter, N-terminal part of <i>yfp</i> (491 bp) and 503 bp of <i>Smatg8</i> ORF with stop codon, <i>trpC</i> terminator (765 bp) in pRS-YN	This study
pRS-egfp-Smatg8	1023 bp of the 5'-flanking region of <i>Smatg8</i> , <i>egfp</i> excluding stop codon, <i>Smatg8</i> ORF without start codon and 1021 bp of 3'-flanking region of <i>Smatg8</i> in pRSnat	(Voigt and Pöggeler 2013a)
pegfp-Smatg12	1058 bp of the 5'-flanking region of <i>Smatg12</i> , <i>egfp</i> excluding stop codon, <i>Smatg12</i> ORF without start codon and 1615 bp of 3'-flanking region of <i>Smatg12</i> in pRSnat	(Werner et al. 2016)

## Materials and Methods

pHsnbr1-Dsred	991 bp of the 5'-flanking region of <i>Smnbr1</i> , 2810 bp of cDNA of the <i>Hsnbr1</i> ORF without stop codon, <i>Dsred</i> and <i>trpC</i> terminator (1466 bp) in pRSnat	This study
pSmpex14-egfp	794 bp of the 5'-flanking region and 1250 bp of the ORF of <i>Smpex14</i> without stop codon, <i>egfp</i> and <i>trpC</i> terminator (1506 bp) in pRSnat	This study
pDsred-Smhex1	840 bp of the promoter <i>trpC</i> , <i>Dsred</i> (674 bp), 703 bp of <i>Smhex1</i> ORF and 849 bp of the 3'-flanking region in pRSnat	This study
pSmrpl25-egfp	1000 bp of the 5'-flanking region and 686 bp of the ORF of <i>Smrpl25</i> without stop codon, <i>egfp</i> and <i>trpC</i> terminator (1506 bp) in pRSnat	This study
pSmrps19-egfp	722 bp of the 5'-flanking region and 861 bp of the ORF of <i>Smrps19</i> without stop codon, <i>egfp</i> and <i>trpC</i> terminator (1506 bp) in pRSnat	This study
<b>yeast-two hybrid and maturation assay</b>		
pGADT7	<i>LEU2</i> , <i>adh1<sup>P</sup></i> , <i>adh1<sup>T</sup></i> , <i>GAL4-AD</i> , <i>amp<sup>R</sup></i> , HA tag	Clontech laboratories inc. (Saint-Germain-en-Laye, France), 630442
pGBKT7	<i>TRP1</i> , <i>adh1<sup>P</sup></i> , <i>adh1<sup>T</sup></i> , <i>GAL4-BD</i> , <i>kan<sup>R</sup></i> , myc tag	Clontech laboratories inc. (Saint-Germain-en-Laye, France), 630443
pAD-ranBPM	<i>ranBPM</i> in pGADT7	(Tucker et al. 2009)
pAD-Smatg8	<i>Smatg8</i> cDNA in pGADT7	(Voigt and Pöggeler 2013a)
pBD-Smatg8	<i>Smatg8</i> cDNA in pGBKT7	(Voigt and Pöggeler 2013a)
pAD-Smatg12	<i>Smatg12</i> cDNA in pGADT7	(Werner et al. 2016)
pBD-Smatg12	<i>Smatg12</i> cDNA in pGBKT7	(Werner et al. 2016)
pAD-Smatg7	<i>Smatg7</i> cDNA in pGADT7	(Werner et al. 2016)
pBD-Smatg7	<i>Smatg7</i> cDNA in pGBKT7	(Werner et al. 2016)
pAD-Smatg3	<i>Smatg3</i> cDNA in in pGADT7	(Werner et al. 2016)
pBD-Smatg3	<i>Smatg3</i> cDNA in pGBKT7	(Werner et al. 2016)
pAD-Smnbr1	<i>Smnbr1</i> cDNA in pGADT7	This study

## Materials and Methods

pBD-Smnbr1	<i>Smnbr1</i> cDNA in pGBKT7	This study
pAD-Smnbr1(1-418)	<i>Smnbr1 aa 1-418</i> cDNA in pGADT7	This study
pAD-Smnbr1(419-863)	<i>Smnbr1 aa 419-863</i> cDNA in pGADT7	This study
pAD-Smnbr1(1-843)	<i>Smnbr1 aa 1-843</i> cDNA in pGADT7	This study
pAD-Smnbr1(Y <sup>847</sup> A L <sup>850</sup> A)	<i>Smnbr1 Y<sup>847</sup>A L<sup>850</sup>A</i> cDNA in pGADT7	This study
pAD-Smnbr1(T <sup>843</sup> A)	<i>Smnbr1 T<sup>843</sup>A</i> cDNA in pGADT7	This study
pAD-Smnbr1(T <sup>843</sup> A Y <sup>847</sup> A L <sup>850</sup> A)	<i>Smnbr1 T<sup>843</sup>A Y<sup>847</sup>A L<sup>850</sup>A</i> cDNA in pGADT7	This study

pAD-Smnbr1(S <sup>793</sup> A)	<i>Smnbr1 S<sup>793</sup>A</i> cDNA in pGADT7	This study
pAD-Smrpl25	<i>Smrpl25</i> cDNA in pGADT7	This study
pBD-Smrpl25	<i>Smrpl25</i> cDNA in pGBKT7	This study
pAD-Smrps19	<i>Smrps19</i> cDNA in pGADT7	This study
pBD-Smrps19	<i>Smrps19</i> cDNA in pGBKT7	This study
pRS-met25-Smatg12	<i>Smatg12</i> under control of <i>met25</i> promoter, <i>URA3</i> , <i>amp<sup>R</sup></i>	(Werner et al. 2016)
pRS-met25-Scatg12	<i>Scatg12</i> under control of <i>met25</i> promoter, <i>URA3</i> , <i>amp<sup>R</sup></i>	(Werner et al. 2016)
pRS315-GFP-ScAtg8	<i>egfp-Scatg8</i> under control of endogenous promoter, <i>LEU2</i> ; <i>amp<sup>R</sup></i>	Thumm pers. comm., Göttingen

*gpd* promoter of glycerin aldehyde 3-phosphate dehydrogenase gene from *A. nidulans*; *ccg1*, promoter of the clock-controlled gene 1 from *N. crassa*; *trpC* promoter and terminator from the anthranilate synthase gene of *A. nidulans*; *amp<sup>R</sup>*, ampicillin resistance; *kan<sup>R</sup>*, kanamycin resistance; *hph*, hygromycin B phosphotransferase gene; *hyg<sup>R</sup>*, hygromycin resistance; *nat*, nourseothricin N-acetyl transferase gene; *nat<sup>R</sup>*, nourseothricin resistance; *cm<sup>R</sup>*, chloramphenicol resistance; *adh1<sup>P</sup>*, *S. cerevisiae adh1* promoter; aa, amino acids.

### 2.1.3 Primers

**Table 4: Overview of the used oligonucleotides.**

Oligo	Sequence 5'-3'	Binding position
<b>localization or multiple usage ATG12</b>		
06998_f	ATGGCATCCCCACAACCCCC	<i>Smatg12</i> ORF bp 1 to 20
06998_r	TCAGGTCCAGAGCAAGTAGT	<i>Smatg12</i> 3' region bp 825 to 805

Materials and Methods

Atg12-gfp-5f	<i>GTAACGCCAGGGTTTTCCAGTCACGACG</i> <i>ACATACAGCCCAATTGATGG</i>	<i>Smatg12</i> 5' region bp -999 to -979, 29-bp overhang to pRS426
Atg12-gfp-5r	<i>GTGAACAGCTCCTCGCCCTTGCTCACCAT</i> <i>TTTGGGAAATTTAATGAGTG</i>	<i>Smatg12</i> 5' region bp -1 to -20, 29-bp overhang to <i>egfp</i>
Atg12-gfp-3f2	<i>TCACTCTCGGCATGGACGAGCTGTACAAG</i> <i>GCATCCCCACAACCCCCATT</i>	<i>Smatg12</i> ORF bp 4 to 24, 29-bp overhang to <i>egfp</i>
Atg12-gfp-3r	<i>GCGGATAACAATTTACACAGGAAACAGC</i> <i>CGGTGCTTTCGCCATGGTGC</i>	<i>Smatg12</i> 3' region bp 1585 to 1565, 29-bp overhang to pRS426

**yeast complementation ATG12**

Atg12_Cf	<u>ACTAGTATGGCATCCCCACAACCCCC</u>	<i>Smatg12</i> cDNA bp 1 to 20, <i>SpeI</i> -restriction site
Atg12_Cr	<u>GTCGACTTACCCAAAAGACGGGGTCA</u>	<i>Smatg12</i> cDNA bp 480 to 461, <i>SallI</i> -restriction site
Scatg12-f	<i>ATACTCTAGA</i> <u>ACTAGTATGAGTAGGATCC</u> <i>TAGAGAG</i>	<i>Scatg12</i> cDNA bp 1 to 20, 16-bp overhang to pRSmet25 including <i>SpeI</i> -restriction site
Scatg12-r	<i>GCTTGATATCGAATTC</i> <u>TTAACCAAACGCT</u> <i>ACGGATG</i>	<i>Scatg12</i> cDNA bp 561 to 541, 16-bp overhang to pRSmet25 including <i>EcoRI</i> -restriction site

**localization, overexpression or multiple usage NBR1**

GFP-f	ATGGTGAGCAAGGGCGAGGAGC	<i>egfp</i> ORF bp 1 to 22
GFP-r	CTTGACAGCTCGTCCATGCCGAGAGTG	<i>egfp</i> ORF bp 717 to 689

Smrps19-c3	CCC <u>CTGCAGT</u> TACTCGTCATCCTCCTCCTC ATC	<i>Smrps19</i> cDNA bp 470 to 446, <i>PstI</i> -restriction site

### 2.1.4 Chemicals and materials

Acetic acid (Roth GmbH, 3738.2), acetonitrile (Roth GmbH, 8825), acrylamide (Rotiphorese® Gel 40 37,5:1) (Roth GmbH, 3029.1), adenine (Sigma-Aldrich, 01830-50G), agar-agar (Roth GmbH, 5210.2), agar-agar SERVA high gel-strength (SERVA, 11396.03), agarose (Biozym Scientific GmbH, 840004), albumin bovine (Sigma-Aldrich, A9647-50G), 3-amino-1,2,4-triazole (3-AT) (Sigma-Aldrich, A8056-100G), ammonium bicarbonate (Sigma-Aldrich, A6141), ammonium chloride (VWR International, BDH0208-500G), ammonium iron (II) sulfate (Roth GmbH, 203505-5G), ammonium sulfate (AppliChem, A1032,1000), ampicillin (Sigma-Aldrich, A9518-25G), arginine (AppliChem, A3709,0250), ammonium persulfate (APS) (Roth GmbH, 9592.3), bacto-yeast-extract (Oxoid LTD, LP0021), bio malt maize extract (Brau-Partner Kling, 115), biotin (Sigma-Aldrich, B4501-1G), boric acid (Roth GmbH, 6943.1), bromophenol blue (AppliChem, A3640,0005), C18 Solid phase extraction Disk (Neuss, 2215, 3M), calcium chloride (Roth GmbH, CN92.1), calcium chloride dihydrate (Roth GmbH, 5239.1), calcofluor white (Sigma-Aldrich, 18909) carbonic anhydrase from bovine erythrocytes (Sigma-Aldrich, C3934-100MG), chloramphenicol (Sigma-Aldrich, C0378), chloroform (Merck Millipore, 1024451000), citric acid-monohydrate (Sigma-Aldrich, C7129), 7-amino-4-chloromethylcoumarin (CMAC) (Invitrogen, C-2110), Coomassie brilliant blue R250 (Roth GmbH, 3862.1), Coomassie brilliant blue G250 (Roth GmbH, 9598.1), CSM-Ade-His-Leu-Trp-Ura (MP Biomedicals, 4550-122), 4',6-Diamidine-2'-phenylindole (DAPI) (AppliChem, A1001), dialysis filter (Merck Millipore, VSWP01300), 2'-deoxy-nucleotids-5'triphosphate (dNTPs) (Thermo Scientific, R0191), Difco™ skim milk (BD Biosciences, 232100), deoxyribonucleic acid single stranded from salmon testes (ss-DNA) (Sigma Aldrich, D1626-1G), Difco™ yeast nitrogen base w/o amino acids and ammonium sulfate (BD Biosciences, 233520), disodium hydrogen phosphate (Merck-Millipore, 1065855000), DMF (dimethylformamide) (Roth GmbH, T921.1), dimethyl sulfoxide (DMSO) (Merck Millipore, 1029310500), 1,4-Dithiothreitol (DTT) (AppliChem, A1101,0025), EDTA-free protease inhibitor cocktail (Roche, 04693132001), ethylenediamine tetraaceticacid disodium salt dihydrate (EDTA) (Roth GmbH, 8043.2), electroporation cuvettes (VWR International, 732-1137), ethanol (VWR International, 20821.321), ethidium bromide (Sigma-Aldrich, 46065), "Flat Optical 8-Cap Strip" 0.2 ml (Biozym, 712100), formaldehyde (Roth GmbH, 4979.2), formamide (Sigma-Aldrich, 47670), formic acid (Merck Millipore, 1002641000), FM4-64 (Invitrogen, F34653), GeneRuler 1 kb DNA ladder (Thermo Scientific, SM0313), "GeneScreen Hybridization Transfer Membrane" (PerkinElmer Lifesciences, NEF988001PK), GFP-Trap agarose beads (Chromotek, gta-10), glass beads Ø 0.25-0.5 mm (Roth GmbH, A553.1), glass beads Ø 2.85-3.45 mm (Roth GmbH, A557.1), glucose (AppliChem, A3617,1000), glycine (Roth GmbH, 0079.1), glycerol (VWR International, 24388.295), HEPES (4-(2-hydroxyethyl)-

1-piperazineethanesulfonic acid) (Roth GmbH, 9105.4), histidine (Merck Millipore, 1.04351.0025), hydrochloric acid (Roth GmbH, 4625.2), hydrogen peroxide 30 % (H<sub>2</sub>O<sub>2</sub>) (Merck Millipore, 8.22287.2500), hygromycin B (Merck Millipore, 400051-10MU), high performance chemiluminescence film (Amersham Hyperfilm™ ECL, 28906837), iodoacetamide (Sigma-Aldrich, I1149), isopropyl-β-D-galactopyranoside (IPTG) (Roth GmbH, 2316.3), iron (II) chloride (Roth GmbH, 231-753-5), iron (II) sulfate heptahydrate (Sigma-Aldrich, 31236), imidazole (Roth GmbH, X998.1), isopropanol (AppliChem, A0900,2500GL), kanamycin sulfate (Sigma-Aldrich, 60615), leucine (AppliChem, A1426,0100), lithium acetate (Roth GmbH, 5447.1), maize flour (Mühle Levers, Bochum, Germany; Mühle Udo Kellner, Schimberg, Germany), magnesium chloride hexahydrate (Merck Millipore, 1.05833.1000), magnesium sulfate heptahydrate (Roth GmbH, P027.2), manganese (II) chloride tetrahydrate (Roth GmbH, T881.1), manganese (II) sulfate monohydrate (Roth GmbH, 4487.1), methanol (VWR International, 20864.320), nitrocellulose blotting membrane (GE Healthcare, 10600003), Nonidet® P40 (NP-40) (AppliChem, 9016-45-9), nourseothricin (WernerBioAgents, 5004000), nylon membrane (GE Healthcare, RPN203B), PAGERULER™ Prestained Protein Ladder (Thermo Fisher, SM0671), PEG 4000 (AppliChem, A1249), PEG 6000 (Sigma-Aldrich, 81255), phenol (AppliChem, A1153,0500), phosphoric acid (Roth GmbH, 6366.1), PMFS (phenylmethylsulfonyl) fluoride (Sigma-Aldrich, P-7626), ponceau S (Sigma Aldrich, P3504), potassium acetate (Merck Millipore, 1.04820.1000), potassium chloride (AppliChem, A3582), potassium dihydrogen phosphate (Merck Millipore, 1.04873.1000), potassium hydroxide (Roth GmbH, 6751.1), potassium nitrate (Merck Millipore, 1.05063.1000), sodium dodecyl sulfate (SDS) (Roth GmbH, 4360.2), sodium acetate (Roth GmbH, 6773.2), sodium chloride (AppliChem, A3597,1000), sodium dihydrogen phosphate monohydrate (Merck Millipore, 1.06346.1000), sodium hydroxide (VWR International, 28244.295), sodium molybdate-dihydrate (Sigma-Aldrich, 31439), sorbitol (Roth GmbH, 6213.1), β-mercaptoethanol (Roth GmbH, 4227.1), sterile filter 0.45/0.2 μm (Sarstedt, 83.1826/83.1826.001), sucrose (AppliChem, A4734,1000), TEMED (N,N,N',N'-tetramethylethylenediamine) (Roth GmbH, 2367.3), Tris (tris-hydroxymethyl-aminomethane) (Roth GmbH, AE15.2), trichloroacetic acid (TCA) (Sigma-Aldrich, 91230), tris/HCl (Roth GmbH, 9090.3), Trizol (Invitrogen, 15596026), tryptone/peptone (Roth GmbH, 8952,2), tryptophan (MP Biomedicals, 4061-012), Tween 20® (AppliChem, A4974), uracil (MP Biomedicals, 4061-212), urea (Roth GmbH, 2317.3), whatman paper B002 580x600 mm (Schleicher & Schuell, 88-3852), xylene cyanol (AppliChem, A4976,0005), yeast extract (Roth GmbH, 2904.1), zinc chloride (Sigma-Aldrich, 14424), zinc sulfate heptahydrate (Roth GmbH, K301.1).

### 2.1.5 Kits

AlkPhos Direct Labelling and Detection Kit (Amersham, GE Healthcare, RPN3680), Immobilon™ Western HRP Substrate (Merck Millipore, WBKLS0100), FastGene plasmid Mini Kit (Nippon Genetics Co., Ltd, Lot. 15048), Qiagen PCR Cloning Kit (Qiagen, 231124), QIAprep Spin Miniprep Kit (Qiagen, 27106), QIAquick Gel Extraction Kit (Qiagen, 28704), QIAquick PCR Purification Kit (Qiagen, 28104), Transcriptor High Fidelity cDNA Synthesis Kit (Roche, 05091284001), ZR fungal/Bacterial DNA mini prep (Zymoresearch, D6005).

### 2.1.6 Enzymes

Calf Intestine Alkaline Phosphatase (CIAP) (Thermo Scientific, EF0341), DNase I (Thermo Scientific, EN0521), lambda phosphatase (New England Biolabs GmbH, P0753), lysozyme (Serva, 28262.03), MolTaq DNA polymerase (Molzym, P-010-1000), natuzym (Schliessmann, 5090), Phusion® Hot Start High-Fidelity DNA polymerase (Thermo Scientific, F-549S), restriction endonucleases (Thermo Scientific), RNase A (Roth GmbH, 7164.1), phosphatase inhibitor cocktail tablets (Roche, 04693132001), T4 DNA ligase (Thermo Scientific, EL0011), trypsin digestion buffer (SERVA Electrophoresis, 37283.01).

### 2.1.7 Buffers and solutions

#### Antibiotics/antimycotics

Ampicillin stock solution:	100 mg/ml in A. dest.
Kanamycin stock solution:	50 mg/ml in A. dest.
chloramphenicol:	50 mg/ml in A. dest.
hygromycin:	110 U/ml
nourseothricin dihydrogen sulfate:	50 µg/ml

#### Transformation and supplementation of *S. macrospora*

Protoplasting buffer (PPP):	13 mM Na <sub>2</sub> HPO <sub>4</sub> , 45 mM KH <sub>2</sub> PO <sub>4</sub> , 0.6 M KCl, pH 6.0
Transformation buffer (TPS):	1 M sorbitol, 80 mM CaCl <sub>2</sub> , pH 7.4 TPS with 25 % PEG (PEG6000)
Topagar:	0.8 M NaCl, 0.8 % agar-agar, 0.025 % hygromycin B (110 U/ml), 0.025 % nourseothricin dihydrogen sulfate (50 µg/ml)
Trace-element stock solution:	5 % (w/v) citric acid (C <sub>6</sub> H <sub>8</sub> O <sub>7</sub> monohydrate), 5 % (w/v) ZnSO <sub>4</sub> heptahydrate, 1 % (w/v) Fe(NH <sub>4</sub> ) <sub>2</sub> (SO <sub>4</sub> ) <sub>2</sub> hexahydrate,

## Materials and Methods

---

	0.25 % (w/v) CuSO <sub>4</sub> pentahydrate,
	0.05 % (w/v) MnSO <sub>4</sub> monohydrate,
	0.05 % (w/v) H <sub>3</sub> BO <sub>3</sub> ,
	0.05 % (w/v) Na <sub>2</sub> MoO <sub>4</sub> dihydrate
Biotin stock solution:	0.01 % (w/v) biotin, 50 % (v/v) ethanol
Arginine stock solution:	100 mg/ml in A. dest.

*S. macrospora* lysis buffer (gDNA): 10 mM Tris/HCl (pH 8.0), 1 mM EDTA, 100 mM NaCl,  
2 % SDS

Preparation agar: 5 % (w/v) agar-agar in A. dest.

### **Transformation and supplementation of *S. cerevisiae***

Lithium acetate (10x):	1 M lithium acetate, pH 7.5
TE (10x)	100 mM Tris (pH 8.0), 10 mM EDTA
LiAcTE(D) (1x):	1ml lithium acetate (10x), 1ml TE (10x), A. dest.
DTT:	1M DTT in H <sub>2</sub> O
Sorbitol:	1M sorbitol in H <sub>2</sub> O
LiAcTE(D) + PEG:	50 % (w/v) PEG 4000, in 1x (v/v) LiAcTE(D)
Salmon sperm (ss) DNA:	1 % (w/v) ssDNA

### **Amino acid stock solutions (yeast)**

Adenine stock solution:	0.02 % (w/v) adenine in A. dest., final conc. 0.002 %
Leucine stock solution:	1 % (w/v) leucine in A. dest., final conc. 0.003 %
Histidine stock solution:	1 % (w/v) histidine in A. dest., final conc. 0.002 %
Uracil stock solution:	0.02 % (w/v) uracil in A. dest., final conc. 0.002 %
Tryptophan stock solution:	0.02 % (w/v) tryptophan in A. dest., final conc. 0.002 %

### **DNA methods**

dNTP mix (10 mM):	10 mM dATP, dCTP, dGTP, dTTP each in A. dest.
EtBr stock solution:	10 mg/ml ethidium bromide in A. dest.
DNA loading dye (6x):	0.25 % (w/v) xylene cyanol, 0.25 % (w/v) bromophenol blue, 40 % (w/v) sucrose
TBE (10x):	1 M Tris/HCl, 1 M boric acid, 20 mM EDTA, pH 8.3
Agarose gel:	1 % (w/v) agarose in 1x TBE

**Plasmid isolation according to Birnboim and Doly (1979)**

BD solution I:	50 mM glucose, 10 mM EDTA, 25 mM Tris/HCl, 0.2 % lysozyme
BD solution II:	0.4 M NaOH, 2 % (w/v) SDS (mixed 1:1)
BD solution III:	3 M potassium acetate, 1.8 M formic acid

**Protein methods**

5x SDS-PAGE loading dye:	125 mM Tris/HCl (pH 6.8), 50 % (v/v) glycerol, 2 % (w/v) SDS, 0.01 % (w/v) bromophenol blue, 0.01 % (w/v) $\beta$ -mercaptoethanol
TBST(10x):	100 mM Tris/HCl (pH 7.5), 1.5 M NaCl, 0.1 % (v/v) Tween 20 <sup>®</sup> (add fresh)
Skim milk blocking solution:	5 % (w/v) Difco <sup>™</sup> skim milk in 1xTBST
Ponceau staining solution:	0.2 % Ponceau S, 3 % TCA
SDS-PAGE-running buffer:	1.5 % (w/v) Tris (pH 8.3), 9.4 % (w/v) glycine, 20 % (w/v) SDS
Lysis buffer ( <i>S. macrospora</i> , protein):	10 mM Tris (pH 7.5), 150 mM NaCl, 0.5 mM EDTA (pH 8.0), 2 mM DTT, 1 mM PMSF, 1x protease inhibitor cocktail, 10 % glycerol, 0.5 % NP-40
Dilution buffer:	10 mM Tris (pH 7.5), 150 mM NaCl, 0.5 mM EDTA (pH 8.0), 1 mM PMSF, 1x protease inhibitor cocktail
Lysis buffer ( <i>S. cerevisiae</i> ):	1.85 M NaOH, 7.5 % (v/v) $\beta$ -mercaptoethanol
fixing solution	45 % ethanol 10 % acetic acid
Coomassie staining solution:	0.02 % (w/v) Coomassie brilliant blue R250, 0.02 % (w/v) Coomassie brilliant blue G250, 42.5 % (v/v) ethanol 0.5 % (v/v) methanol 10 % (v/v) acetic acid
SDS solution:	10 % (w/v) SDS in A. dest.
Transfer buffer:	192 mM glycine, 25 mM Tris, 20 % (v/v) methanol, 0.02 % SDS
Buffer b:	100 mM Tris/HCl (pH 7.5), 200 mM NaCl, 20 % glycerol, 5 mM EDTA

Buffer b+: buffer b + 1x protease inhibitor cocktail,  
0.5 %  $\beta$ -mercaptoethanol

### **PXG (pellet X-Gal) assay**

Phosphate buffered saline (PBS, 10x): 1.4 M NaCl, 27 mM KCl, 100 mM Na<sub>2</sub>HPO<sub>4</sub>, 17.6 mM KH<sub>2</sub>PO<sub>4</sub>, pH 7.4  
X-Gal: 2 % (w/v) in DMF

### **Southern blot solutions**

Buffer I: 0.25 M HCl  
Buffer II: 0.5 M NaOH, 1.5 M NaCl  
Buffer III: 1.5 M NaCl, 0.5 M Tris  
First washing buffer: 2 M Urea, 0.1 % (w/v) SDS, 50 mM NaH<sub>2</sub>PO<sub>4</sub> x H<sub>2</sub>O (pH 7.0),  
150 mM NaCl, 1mM MgCl<sub>2</sub>, 0.2 % blocking reagent  
Second washing buffer (20x): 1 M Tris, 2 M NaCl, 1 mM MgCl<sub>2</sub>, pH 10.0  
Prehybridisation buffer: 0.5 M NaCl with 4 % “blocking reagent”

## **2.1.8 Cultivation media**

### *E. coli*

**LB (Luria-Bertani):** 1 % (w/v) tryptone, 0.5 % yeast extract, 0.5 % NaCl, pH 7.2; 1.5 % (w/v) agar-agar for solid medium; addition of ampicillin (100  $\mu$ g/ml), kanamycin (50  $\mu$ g/ml) or chloramphenicol (50  $\mu$ g/ml) for selection.

**SOB (super optimal broth):** 2 % (w/v) tryptone, 0.5 % (w/v) yeast extract, 10 mM NaCl, 2.5 mM KCl, 10 mM MgCl<sub>2</sub>, 10 mM MgSO<sub>4</sub>, H<sub>2</sub>O, pH 7.0

**TB:** 10 mM HEPES, 15 mM CaCl<sub>2</sub> x 2H<sub>2</sub>O, 250 mM KCl, 55 mM MnCl<sub>2</sub> x 4H<sub>2</sub>O, pH 6.7

### *S. cerevisiae*

**YEPD (yeast extract, peptone, dextrose):** 2 % (w/v) tryptone, 2 % (w/v) glucose, 1 % (w/v) yeast extract, pH 5.8; 1.5 % (w/v) agar-agar for solid medium.

**SD (synthetic defined):** 0.17 % (w/v) Difco™ yeast nitrogen base w/o amino-acids and ammonium sulfate, 2 % (w/v) glucose, 0.5 % (w/v) ammonium sulfate, 0.064 % (w/v) CSM-Ade-His-LeuTrp-Ura (0.002 % L-methionine, 0.005 % L-arginine hydrochloride, L-isoleucine, L-lysine hydrochloride, L-phenylalanine, L-tyrosine each, 0.008 % L-aspartic acid, 0.01 % and L-threonine, 0.014 % L-valine), pH 5.8; 2 % (w/v) agar-agar SERVA for solid medium. Selection of transformants was performed by exclusion of respective amino acid(s).

**S. macrospora**

**BMM (biomalt maize medium):** 0.8 % (w/v) bio malt maize extract and maize flour (25 g/L), pH 6.5; 1.5 % (w/v) agar-agar for solid medium; addition of hygromycin B (110 U/ml) or nourseothricin dihydrogen sulfate (50 µg/ml) for selection.

**BMM sodium acetate:** BMM + 0.5 % (w/v) sodium acetate (sporulation induction); 1.5 % (w/v) agar-agar for solid-medium.

**CMS (complex media, sucrose):** 1 % (w/v) glucose, 0.2 % (w/v) tryptone/peptone, 0.2 % (w/v) yeast extract, 0.15 % (w/v) KH<sub>2</sub>PO<sub>4</sub>, 0.05 % (w/v) KCl, 0.05 % (w/v) MgSO<sub>4</sub> heptahydrate, 0.37 % (w/v) NH<sub>4</sub>Cl, 10.8 % (w/v) sucrose, 0.01 % (v/v) trace-element stock solution (10 mg/l ZnSO<sub>4</sub>, 10 mg/l Fe(II)Cl<sub>2</sub>, 10 mg/l MnCl<sub>2</sub>), pH 6.5; 1.5 % (w/v) agar-agar for solid medium.

**SWG (*Sordaria* Westergaards medium):** 1x Westergaard's (0.1 % (w/v) KNO<sub>3</sub>, 0.1 % (w/v) KH<sub>2</sub>PO<sub>4</sub>, 0.05 % (w/v) MgSO<sub>4</sub> heptahydrate, 0.01 % (w/v) NaCl, 0.01 % (w/v) CaCl<sub>2</sub>, [0.01 % (v/v) trace-element stock solution + 0.1 % (v/v) chloroform]), 2 % (w/v) glucose, 0.1 % (w/v) arginine, 0.1 % (v/v) biotin stock solution, pH 6.5; 1.5 % (w/v) agar-agar for solid medium; addition of hygromycin B (110 U/ml) or nourseothricin dihydrogen sulfate (50 µg/ml) for selection.

**SWG 0.5 %G+OA:** SWG but glucose is reduced to 0.5 %, 0.15 % (w/v) oleic acid, 0.05 % (w/v) NP-40.

**SWG-G+OA:** SWG without glucose, 0.15 % oleic acid, 0.05 % NP-40.

## 2.2 Methods

### 2.2.1 Cultivation of organisms

#### *E. coli*

Cultivation of *E. coli* strains was done at 37°C on solid LB medium or in liquid LB medium while shaking at 180 rpm. Selection was carried out by the addition of 100 µg/ml ampicillin, 50 µg/ml kanamycin or 50 µg/ml chloramphenicol.

#### *S. cerevisiae*

Yeast strains were inoculated on solid YEPD medium (complete medium) and solid SD-medium (minimal medium) supplemented with appropriate amino acids and incubated at 30°C. Liquid cultures were incubated in corresponding liquid medium while shaking at 100 rpm.

#### *S. macrospora*

Cultivation of *S. macrospora* strains was conducted on solid corn meal medium (BMM), complex rich medium containing 10.8 % sucrose (CMS) and fruiting-body development inducing SWG medium at 27°C with continuous light. For phenotypic analysis under different stress conditions the temperature was changed or SWG medium was supplemented with 2.5 mM 3-amino-1,2,4-triazole (3-AT), 0.5 M sorbitol, 0.25 M NaCl, 0.01 %, 0.02 %, 0.05 % H<sub>2</sub>O<sub>2</sub> or 0.005 % SDS, respectively. To induce nitrogen starvation SWG was modified by omitting KNO<sub>3</sub>, arginine and biotin or in combination. Liquid cultures were grown in corresponding liquid medium at 27°C in petri dishes. For analysis of the growth velocity, 30-cm race tubes were filled with 25 ml of solid SWG medium or stress-inducing medium and inoculated with a mycelia plug of 0.5 cm in diameter at one end (Nolting and Pöggeler 2006). The growth front was marked every 24 h for five consecutive days of three replications in triplets. The growth rate was calculated in cm per day. All quantitative analyses of *S. macrospora* strains were done using SWG medium and were analyzed statistically as described in 2.2.6.3. For phenotypic analysis and light microscopy *S. macrospora* strains were grown on cellophane or glass slides covered with solid SWG or BMM medium at 27°C with continuous light. The growth period differed between 3-10 d depending on the developmental stage. To induce sexual development in liquid media, *S. macrospora* was grown in liquid BMM medium at 27°C in floating cultures. To prevent sexual development in liquid medium *S. macrospora* was cultivated in Erlenmeyer flasks with 100 ml of liquid BMM medium shaken at 130 rpm at 27°C.

### 2.2.2 Preparation and transformation of competent microorganisms

#### *E. coli*

Chemically competent *E. coli* MACH1 cells (Invitrogen (Carlsbad, USA)) were prepared by inoculation of a few colonies in 50 ml SOB in a 250 ml Erlenmeyer flask while shaking overnight at 20°C and 50 rpm. After incubation, and when the optical density of 600 nm (OD<sub>600</sub>) had reached 0.6, the cells were kept on ice for 10 min and harvested by centrifugation at 3000 rpm at 4°C for 10 min. The cells were resuspended in 16 ml TB and kept on ice for further 10 min, followed by centrifugation at the same conditions as the last step. The cell pellet was resuspended in 4 ml TB plus 280 µl DMSO and incubated on ice for 10 min. The cells were aliquoted to 1.5 ml cups and frozen in liquid nitrogen for storage at -80°C. For transformation of chemically competent *E. coli* MACH1 cells plasmid DNA was added to thawed competent cells and incubated for 30 min on ice (Sambrook and Russell 2001). After a 90 sec heat shock at 42°C, cells were incubated on ice for 2 min followed by the addition of 800 µl liquid LB and incubation for 1 h at 37°C and 200 rpm. Cells were plated on solid LB medium with 100 µg/µl ampicillin, 50 µg/µl kanamycin or 50 µg/µl chloramphenicol.

#### *S. cerevisiae*

*S. cerevisiae* strain PJ69-4A was used as host for homologous recombination experiments performed according to Colot et al. (2006). For the preparation of electro-competent *S. cerevisiae* cells, a 50 ml culture was grown to an OD<sub>600</sub> of 0.6 -1.2 in YEPD. The cells were subsequently pelleted and incubated with 1x LiAcTE(D). After 45 min at 30°C and 100 rpm, 0.5 ml 1M DTT were added. After additional incubation at 30°C and 100 rpm for 15 min the cells were washed with A. dest. and 1 M sorbitol. For the transformation 40 µl competent cells were mixed with 500 ng DNA and electroporated in 0.2 cm electroporation cuvettes in the “Eppendorf Electroporator 2510” (Eppendorf, Germany) at 1.5 kV. After electroporation, 800 µl of 1 M sorbitol were added and 200 µl portions of the yeast suspension were plated on respective solid selection medium.

Another lithium acetate transformation method was used as described by Ito et al. (1983). For this, a 10 ml culture was grown to an OD<sub>600</sub> of 0.6 -1.2 in YEPD at 30°C in a rotating wheel. Afterwards, the cultures were spun down for 4 min at 4000 rpm in a 15 ml falcon tube. The supernatant was discarded and the pellet resuspended in 4 ml 1x LiAcTE(D). Afterwards, the cells were again spun down and resuspended in approximately 360 µl 1x LiAcTE(D), resulting in 400 µl cell suspension. Each 200 µl were utilized for one transformation. To each transformation sample 20 µl of ssDNA, 1-3 µl of the plasmid of interest and 800 µl 50% 1x

LiAcTE(D)+PEG were added and the transformation sample was mixed. After an incubation of 30 min at 30°C the cells were heat shocked for 25 min at 42°C followed by a centrifugation for 30 sec at 7000 rpm. The pelleted cells were resuspended in 800 µl liquid YEPD and incubated on a rotary shaker at 30°C for 1 h. Finally, the cells were pelleted again, resuspended in the remaining supernatant and plated on SD medium with 2 % agar lacking the specific amino acids or nucleic acids necessary for selection. The samples were then incubated at 30°C until growth was observed.

### **S. macrospora**

Standard transformation protocols for *S. macrospora* were conducted as described previously (Pöggeler et al. 1997; Nowrousian et al. 1999). For the transformation of *S. macrospora* protoplasts had to be prepared. Mycelium was inoculated in liquid BMM medium with 6-8 agar plugs. After three days the mycelium was harvested and transferred into a sterile 250 ml flask and incubated with 0.4 g natuzyme in 20 ml PPP buffer for 2 h at 27°C and 100 rpm. The next step was the separation of the cell debris from the protoplasts. Therefore, the protoplast solution was transferred to a filter (frit, pore size 1) to remove the debris and collect the protoplasts in falcon tubes. The solution was filled up to 50 ml with PPP buffer and centrifuged (4 min, 4°C, 4400 rpm). After this step the protoplast solution was washed with 10 ml PPP buffer and subsequently centrifuged (4 min, 4°C, 4400 rpm). The pelleted protoplasts were resuspended in 100-200 µl TPS buffer and 20 µg DNA were mixed with 100 µl protoplasts and incubated for 10 min on ice. After the addition of 200 µl PEG 6000 TPS (0.25 g/ml) the solution was incubated for 20 min at RT. Finally, the mixture was plated on solid CMS medium in 150 µl aliquots. On the next day the plates were covered with 9 ml topagar containing the appropriate antibiotic. Positive primary transformants were isolated after 1-3 d.

### **2.2.3 Construction of single-spore isolates of *S. macrospora***

Heterokaryotic primary transformants that were able to form perithecia were directly used to generate homokaryotic single-spore isolates. Otherwise, the strains were crossed with the spore-color mutant strain *fus1-1* to produce hybrid perithecia. The *fus1-1* strain has lost its ability to produce melanin resulting in brown ascospores (Nowrousian et al. 2012). For this, two different *S. macrospora* strains were crossed by placing two agar pieces (0.25 cm<sup>2</sup>), each containing one strain, towards each other in a distance of 5 cm on a petri dish with solid SWG medium. After incubation for 8-10 d at 27°C, the crossing front is formed in the middle of the petri dish containing the recombinant perithecia. The recombinant hybrid perithecia contain asci with 4

brown (*fus1-1* strain) and 4 black ascospores in typical 4:4 or 2:2:2:2 segregation patterns. Single-spore isolates (ssi) were done by transferring and opening the recombinant perithecia on preparation agar using a Zeiss “Stemi 2000-C” stereo microscope (Zeiss). Single spores were collected with a sterile needle and placed on solid BMM sodium acetate medium, supplemented with either hygromycin B (110 U/ml) or nourseothricin dihydrogen sulfate (50 µg/ml) or both for selection.

## **2.2.4 Molecular biological methods**

### **2.2.4.1 Preparation of DNA**

#### **2.2.4.1.1 Isolation of plasmid DNA from *E. coli***

For the extraction of plasmid DNA from *E. coli* two different kits were used according to the manufacturer’s manual: the QIAprep Spin Miniprep or the FastGene plasmid Mini Kit. In addition, a modified plasmid extraction protocol according to Birnboim and Doly (1979) was used. For this purpose an *E. coli* 5 ml LB culture with the appropriate antibiotic was grown over night at 37°C and 200 rpm. The cells were harvested by centrifugation at 5000 rpm for 5 min. The pellet was vortexed with 200 µl of the BDI solution, 10 µl RNase A (10 mg/ml) and 0.4 mg lysozyme. After 5 min of incubation at RT 200 µl BDII were added to the cell suspension, mixed and stored on ice for 10 min. Subsequently, 200 µl BDIII were added and the solution was mixed by gently inverting the tube followed by 10 min incubation on ice. The supernatant was yielded by centrifugation at 13000 rpm for 10 min and transferred to a new cup. For the precipitation of the DNA 750 µl ice-cold isopropanol were added and incubated at -20°C for at least 20 min. Subsequently, the DNA was harvested with the same speed for 5 min and washed with 500 µl of ice-cold 70 % ethanol. Again, the DNA was pelletized before the supernatant was discarded and the pellet was dried before dissolving in 100-200 µl A. dest.

#### **2.2.4.1.2 Plasmid DNA isolation from *S. cerevisiae***

To isolate recombinant plasmid DNA from *S. cerevisiae* transformants, cells from selective media plates were removed with a sterile cotton bud and dissolved in 1 ml sterile water. Subsequently, the cells were harvested by centrifugation and the DNA was isolated using the ZR fungal/Bacterial DNA mini prep Kit according to manufacturer’s manual.

#### **2.2.4.1.3 Isolation of genomic DNA and RNA from *S. macrospora***

The isolation of genomic DNA from *S. macrospora* was achieved either by the phenol/chloroform extraction method according to Pöggeler et al. (1997) or a modified sodium acetate/isopropanol precipitation. After growth for three days in liquid BMM medium the mycelium was harvested, dried and grinded in liquid nitrogen. After the addition of 600 µl lysis buffer mycelium powder was incubated for 30 min at 70°C. Afterwards 400 µl of a 3 M sodium acetate solution were added followed by incubation for 10 min at -20°C. The mixture was centrifuged for 10 min at 13000 rpm and the obtained supernatant was mixed with same volume of ice-cold isopropanol and incubated for 20 min at -80°C. After a new centrifugation (10 min, 4°C, 7000 rpm) the pellet was washed with 500 µl ice-cold 70 % ethanol and dried under the hood. The genomic DNA was resuspended in 50-100 µl distilled water.

The extraction of RNA was done according to Elleuche and Pöggeler (2009). In brief, the mycelium was grinded to powder with liquid nitrogen and mixed with 1 ml trizol. After centrifugation for 10 min at 13000 rpm the supernatant was transferred to a new reaction tube and mixed with 0.2 ml chloroform. Again, the mixture was centrifuged and 500 µl of the newly obtained supernatant were mixed with the same volume of ice-cold isopropanol. After incubation for 10 min at RT the RNA was centrifuged, washed with 500 µl ice-cold 70 % ethanol and dried under the hood. Finally, the RNA was resuspended in 120 µl water and incubated for 30 min at 1000 rpm and 60°C.

#### **2.2.4.2 Hydrolysis and ligation of nucleic acids**

Nucleic acids were hydrolyzed using specific restriction endonucleases (1 U/1 µg DNA) according to manufacturer's manual in setups of 10-50 µl. The ligation of nucleic acids was carried out using the T4 DNA ligase as suggested by the manufacturer. Reactions were incubated at RT for 30 min to 2 h. To avoid self-ligation plasmids were treated with "Calf Intestine Alkaline phosphatase" after hydrolysis and prior to ligation.

#### **2.2.4.3 Purification of nucleic acids**

Prior to transformation or ligation experiments salts from the PCR or hydrolysis reactions needed to be removed from the aqueous nucleic-acid solution. Therefore, dialysis filters (Merck-Millipore, Germany) were placed on the water surface within a petri dish and 15 µl of the PCR fragments or the hydrolyzed plasmid DNA were positioned on the top. The dialysis then proceeded for 15 min. Alternatively, the QIAquick PCR Purification Kit was used to purify DNA fragments. Furthermore, DNA could also be loaded on a 1 % agarose gel and DNA

fragments were isolated with the QIAquick Gel Extraction Kit as described by the manufacturer.

#### 2.2.4.4 Polymerase chain reaction (PCR)

The PCR technique was used for *in vitro* amplification of genes or gene fragments from genomic, plasmid or complementary DNA using specific forward and reverse oligonucleotides (Mullis and Faloona 1987). The PCR reactions were performed with either the Phusion® Hot Start High-Fidelity DNA polymerase characterized by a low error rate or the MolTaq DNA polymerase for analytical and colony-PCR. The reactions were carried out in the cycler machines “Eppendorf Mastercycler egradient S” (Eppendorf, Germany) or MyCycler (BioRad, USA) as suggested by the manufacturer’s. Components used for the standard 50 µl PCR reactions for Phusion and MolTaq polymerase were as follows:

**Table 5: Composition of a 50 µl PCR reaction for Phusion-or MolTaq polymerase.**

components	Phusion polymerase	MolTaq polymerase
water	34 µl	35.8 µl
5x reaction buffer	10 µl	10 µl
dNTPs (10 mM)	1 µl	1 µl
primer 1 (10 pM)	1 µl	1 µl
primer 2 (10 pM)	1 µl	1 µl
template DNA (50-100 ng)	1 µl	1 µl
DMSO	1.5 µl	-
polymerase	0.5 µl	0.2 µl

#### 2.2.4.5 Agarose gel electrophoresis of nucleic acids

This electrophoresis method allows the horizontal separation of DNA within an agarose gel due to its size. For this purpose the samples were mixed with 6x loading dye and loaded on a 1 % agarose gel (1g agarose in 100 ml 1x TBE buffer). The DNA was separated by 70-130 V using a gel chamber “Mupid one” (Biozym Scientific GmbH, Germany) filled with 0.5 % TBE buffer. The GeneRuler™ 1 kb DNA Ladder was used as standard. Subsequently, the gel was stained with 0.0001 % ethidium bromide solution for 15 min and visualized by UV transillumination. The result was documented with the „BioDocAnalyzer“ (Biometra, Germany).

#### **2.2.4.6 Southern blot and hybridization**

Deletion of genes was verified by Southern hybridization (Southern 1975). First, 30-50 µg of gDNA was hydrolyzed in a 50 µl reaction volume and separated on a 1 % agarose gel for 90-120 min at 90 V. After the run, the gel was soaked for 10 min in buffer I (0.25 M HCl), 25 min in buffer II (0.5 M NaOH, 1.5 M NaCl) and 30 min in buffer III (1.5 M NaCl, 0.5 M Tris). A semi-dry blot onto a nylon membrane was performed for 3 h. Afterwards, the membrane was dried for 7 min at 70°C and the DNA was cross-linked via “UV-light exposure” (Biometra, Germany) of each side for 3 min. The AlkPhos Direct Labelling and Detection Kit was used for labeling the defined probe. The hybridization of the membrane with the probe as well as the detection was performed according to the manufacturer’s manual.

#### **2.2.4.7 Oligonucleotide synthesis, sequencing and sequence analysis**

The synthesis of oligonucleotide used in this study was done by Eurofins MWG Operon (Ebersberg, Germany). All primers used for this study are listed in Table 4. DNA sequencing was performed by the G2L-sequencing service of the Göttinger Genom Labor (Georg-August University of Göttingen, Germany) and Seqlab (Sequence Laboratories Göttingen GmbH, Germany). The resulting sequences were analyzed via software Chromas Lite 2.01 (1998-2005 Technelysium Pty Ltd) and compared to the plasmid sequence created in Clone Manager 7 with the use of the nucleotide BLASTN search from the public database at NCBI (<http://www.ncbi.nlm.nih.gov/>). Multiple protein sequence alignments were done using the ClustalX program (Thompson et al. 1997) with sequences of different organisms obtained after BLASTP search from database at NCBI and visualized using the program GeneDoc 2.7.0.0. Molecular weights and isoelectric points were calculated with programs from the ExPASy Proteomics Server (<http://www.expasy.org>) as well as domain analysis of the proteins. Phosphorylation sites were predicted using the online tool NetPhos3.1 (<http://www.cbs.dtu.dk/services/NetPhos>).

#### **2.2.4.8 Phylogenetic analysis**

Multiple protein sequence alignments were performed using the ClustalX alignment program (Thompson et al. 1997). Phylogenetic analysis was made with programs from package PHYLIP version 3.695 (<http://evolution.genetics.washington.edu/phylip.html>). Distance matrices were calculated using the program PRODIST and were then used for constructing phylogenetic trees with the neighbor-joining (NJ) program NEIGHBOR. To evaluate the statistical significance a bootstrap analysis with 1000 iterations of bootstrap samplings and reconstruction of trees was

performed. A majority rule consensus tree was subsequently generated with the program CONSENSE, displayed with TreeView 1.6.6 (Page 1996) and saved for graphical representation with Adobe Illustrator (CS2).

### **2.2.5 Plasmid construction using homologous recombination in yeast**

Yeast cells (PJ69-4A) can perform homologous recombination, which allows for the assembly of circular plasmids from several linear DNA fragments. One 29-bp overhang is required between two fragments or the vector backbone and is sufficient for the yeast cell to activate the DNA repair mechanism (Colot et al. 2006). The assembly of a plasmid by homologous recombination requires a hydrolyzed vector backbone and linear DNA fragments. Knockout plasmids consists of the 5' and 3'-flanking region of the gene of interest interrupted by a resistance cassette whereas plasmids for localization and complementation studies encode native or suitable promoter and terminator regions for expression in respective wanted organism, an open reading frame of the gene of interest (gDNA) and if necessary a gene for a tag. To combine the single fragments into a plasmid, some primers exhibited at least 29-bp overhang to the neighboring regions for homologous recombination reactions in *S. cerevisiae*. The yeast was transformed as described in 2.2.2 and resulting plasmids were isolated from yeast transformants (2.2.4.1.2) and retransformed in *E. coli* cells (2.2.2). The multiplied plasmid was isolated (2.2.4.1.1) and purified (2.2.4.3) for transformation into *S. macrospora* (2.2.2). The same method was sometimes used to generate plasmids for the yeast-two hybrid experiments. Then the cDNA of the gene of interest was combined with the linearized pGADT7 or pGBKT7 vectors.

### **2.2.6 Generation of *S. macrospora* deletion strains**

For generation of *S. macrospora*  $\Delta$ Smnbr1 and  $\Delta$ Smatg12 deletion strains the homologous recombination procedure in *S. cerevisiae* was used to create a plasmid containing the respective knockout construct (Colot et al. 2006) (2.2.5). The deletion constructs consisting of the *hph* resistance cassette flanked by the 5'- and 3'-flanking regions of the gene of interest. After homologous recombination in yeast, the plasmids were isolated and the deletion cassettes were amplified from the respective plasmids, purified and transformed into *S. macrospora* strain  $\Delta$ ku70 which is inhibited in the non-homologous end joining (Pöggeler and Kück 2006). Consequently, the deletion cassette will be integrated by gene replacement at the desired gene locus. Afterwards, the  $\Delta$ ku70 background was eliminated by crossing positive primary

transformants with the spore-color mutant *fus1-1* and single spores of hybrid perithecia were selected on hygromycin media (2.2.3). The constructed single-spore deletion strain was verified by PCR and Southern blot.

### 2.2.6.1 Generation of $\Delta$ *Smnbr1* strain

To delete the *Smnbr1* gene in *S. macrospora* the following knockout construct was constructed according to Colot et al. (2006). The 5' - (1050-bp fragment) and 3' - (785-bp fragment) flanking regions of *Smnbr1* were amplified from wt gDNA using the primer pairs *Smnbr1-ko-5f/Smnbr1-ko-5r* and *Smnbr1-ko-3f/Smnbr1-ko-3r* carrying 29-bp overhangs for the pRS426 vector and the hygromycin resistance B (*hph*) cassette, respectively. The *hph*-cassette (1419-bp fragment) was amplified from plasmid pCB1003 with the primers *hph-f/hph-r*. Subsequently, the three amplicons were co-transformed together with the *XhoI*-linearized vector pRS426 into the yeast strain PJ69-4A as described in 2.2.2 and in Mayrhofer et al. (2006). Transformants were selected on synthetic defined (SD)-medium lacking uracil. The recombinant plasmid p*Smnbr1*-KO, consisting of the upstream and downstream sequence of *Smnbr1* interrupted by the *hph*-cassette, was isolated from yeast as described in 2.2.4.1.2. Plasmid p*Smnbr1*-KO served as template to generate the 3254-bp knockout fragment by PCR with primer pair *Smnbr1-ko-5f/Smnbr1-ko-3r*. The amplicon was desalted and then transformed into *S. macrospora*  $\Delta$ ku70 strain to facilitate the *Smnbr1* knockout by homologous recombination (Pöggeler and Kück 2006). Hygromycin B resistant primary transformants were analyzed by PCR with primer pairs *Smnbr1-v5f/tC1* (1166 bp) and *h3/Smnbr1-v3r* (873 bp) to verify the homologous recombination event at the desired *Smnbr1* gene locus. Primary transformants of *S. macrospora* are usually heterokaryotic carrying  $\Delta$ ku70 (*nat*<sup>R</sup>) and mutant nuclei (*nat*<sup>R</sup>/*hyg*<sup>R</sup>). To obtain homokaryotic deletion mutants and to eliminate the  $\Delta$ ku70 (*nat*<sup>R</sup>) background, primary transformants were crossed with the brown spore-color mutant *fus1-1* (S23442) (Nowrousian et al. 2012). The recombinant hybrid perithecia could be easily identified because the crossing partners differed in their spore color. Black spores from hybrid perithecia were isolated and selected on BMM agar plates containing hygromycin B (110 U/ml) and 0.5 % sodium acetate (2.2.3). The resulting homokaryotic deletion strain  $\Delta$ *Smnbr1* was tested by PCR for the absence of the *Smnbr1* gene using primer pairs *Smnbr1-v5f/Smnbr1-vORF5-r* and *Smnbr1-vORF3-f/Smnbr1-v3r*. gDNA of *S. macrospora* wt strain was used as control and fragment sizes of 1425 bp and 1133 bp were expected. Deletion of *Smnbr1* was verified by Southern hybridization as described in 2.2.4.6 (Southern 1975). Therefore, 30-50  $\mu$ g of gDNA was hydrolyzed with *PstI* (2.2.4.2). The 1050-bp probe was amplified with primer pair *Smnbr1-*

ko-5f/Smnbr1-ko-5r from *S. macrospora* gDNA and purified with the QIAquick gel extraction kit.

### 2.2.6.2 Construction of $\Delta$ Smatg12 strain

The generation of the *Smatg12* knockout strain was done in the same way as for the *Smnbr1* deletion strain by homologous replacement. To delete the *Smatg12* gene in *S. macrospora*, a plasmid was generated containing the 5'- (1058 bp) and 3'- (700 bp) flanking regions of *Smatg12* which were amplified from *S. macrospora* wt gDNA using the primer pairs Atg12\_5f/Atg12\_5r and Atg12\_3f/Atg12\_3r carrying 29-bp overhangs for the pRS426 vector and the hygromycin resistance B (*hph*) cassette, respectively. The *hph*-cassette (1419 bp) was amplified from plasmid pCB1003 with the primers *hph*-f/*hph*-r. Subsequently, the three amplicons were co-transformed together with the *Xho*I-linearized vector pRS426 into the yeast strain PJ69-4A (Mayrhofer et al. 2006). Positive transformants containing the recombinant plasmid pSmatg12-KO were selected on SD-medium lacking uracil. It is characterized by the upstream and downstream sequence of *Smatg12* interrupted by the *hph*-cassette. Plasmid pSmatg12-KO served as template to generate the 3235-bp knockout fragment by PCR with primer pair Atg12\_5f/Atg12\_3r. The amplicon was desalted and transformed into *S. macrospora*  $\Delta$ ku70 strain to facilitate the *Smatg12* knockout by homologous recombination (Pöggeler and Kück 2006). Hygromycin B resistant primary transformants were analyzed by PCR with primer pairs Atg12\_3D1/h3 and tC1/Atg12\_5D1 to verify the homologous recombination event at the desired *Smatg12* gene locus. The heterokaryotic primary transformants of *S. macrospora* carrying  $\Delta$ ku70 (*nat*<sup>R</sup>) and mutant nuclei (*hyg*<sup>R</sup>). To obtain homokaryotic deletion mutants and to eliminate the  $\Delta$ ku70 (*nat*<sup>R</sup>) background, positive primary transformants were crossed with the brown spore-color mutant *fus1-1* (S23442) (Nowrousian et al. 2012) as described in 2.2.3 and 2.2.6.

Single spores from hybrid perithecia were picked and selected on BMM agar plates containing only hygromycin B (110 U/ml) and 0.5 % sodium acetate. The positive homokaryotic  $\Delta$ Smatg12 strain was tested by PCR for the absence of the *Smatg12* gene using primer pair Atg12\_5D1/Atg12\_3D2 in comparison to gDNA of *S. macrospora* wt strain. Additionally, deletion of *Smatg12* was verified by Southern hybridization (Southern 1975). For this, 30 - 50  $\mu$ g of  $\Delta$ Smatg12 gDNA was hydrolyzed with *Bgl*I. The 300-bp probe was amplified with primer pair Atg12\_PRf/Atg12\_PPr from *S. macrospora* gDNA and purified with QIAquick gel extraction kit.

### 2.2.6.3 Morphological investigation of *S. macrospora* deletion strains

The morphological investigation of perithecia and the mycelium growth during the sexual cycle of *S. macrospora* was done with the “Digital Microscope VHX-500F” (Keyence, Germany) or the “AxioImager M1 microscope” (Zeiss, Germany). For this purpose, *S. macrospora* strains were either plated on solid SWG or BMM medium for macroscopic investigations or grown on SWG medium with cellophane or glass slides covered with solid SWG medium at 27°C with continuous light for microscopic investigations (Bloemendal et al. 2012). The growth period differed between 3-10 d depending on the developmental stage. The ascus rosettes were visualized by cracking the perithecia on object slides into a drop of water, the outer perithecia tissue was removed and asci were covered with a cover slide to evoke ascus rosette formation. For examination of the foraging abilities of *S. macrospora* strains, a plug test was performed according to Josefsen et al. (2012). An agar plug with a diameter of 0.5 cm was put into a cell-culture plate (6 well, 17.2 ml) and incubated for five days in a damp chamber at 27°C. All quantitative analysis of *S. macrospora* strains were done using SWG medium. Counting of perithecia per cm<sup>2</sup> was performed after 8 d (wt,  $\Delta$ Smnbr1::Smnbr1-egfp<sup>ect</sup>) or 10 d ( $\Delta$ Smnbr1) of growth with the “Digital Microscope VHX-500F” (Keyence, Germany) from nine independent measurements of three independent experiments (n=27). Discharged ascospores were analyzed after 10 d of growth by washing off the discharged ascospores from the lid of the petri dish, and counting the spores using a thoma cell counter chamber (W. Schreck, Hofheim). The asci in an ascus rosette were also investigated by microscopic observations after 8 d or 10 d. The analysis of the ascospores and asci were statistically analyzed from 25 independent measurements of four independent experiments (n=100). For phenotypic analysis under stress-inducing conditions SWG medium was modified as described in 2.2.1. The SWG medium was inoculated with a mycelia plug of 0.5 cm in diameter in the middle of a petri dish (Ø 9 cm) and after the indicated days investigated by microscopic and macroscopic observations. The phenotypic investigations were done in three biological replicates.

## 2.2.7 Plasmid construction and localization analysis of fluorescence-tagged *S. macrospora* genes

Most of the fluorescence-tagged plasmids were constructed by homologous recombination as described in 2.2.5. These plasmids were used for localization studies as well as to complement the knockout strains by transformation of the plasmids.

### 2.2.7.1 Plasmid construction for *Smatg12*, *Smatg8* and *Smnbr1* fluorescence-tagged versions

For localization of SmATG12 an *egfp*-tagged variant of *Smatg12* under the control of the native promoter and terminator was constructed. The *Smatg12* promoter region was amplified from wt gDNA using primer pair Atg12-gfp-5f/Atg12-gfp-5r (1058-bp fragment) and the coding region including the 3' region of *Smatg12* (1615-bp fragment) with primer pair Atg12-gfp-3f2/Atg12-gfp-3r. The *egfp* was amplified from plasmid p1783-1 using primer pair GFP-f/GFP-r (688-bp fragment). Some fragments exhibit overhangs to the neighbored regions. All fragments were subcloned into the *XhoI*-linearized vector pRSnat by homologous recombination in yeast and resulted in an N-terminally *egfp*-tagged version of *Smatg12* in plasmid pegfp-Smatg12.

To localize the full-length SmNBR1 a C-terminal EGFP-tagged and DsRED-tagged variant of *Smnbr1* under control of the native promoter and *trpC* terminator of *A. nidulans* was constructed. The *Smnbr1* promoter together with the coding region was amplified from wt gDNA using primer pair Nbr1-5f/GFPNbr1r (3731-bp fragment) or Nbr1-5f/DsredNbr1r (3731-bp fragment). The *egfp* (1540-bp fragment) or *Dsred* (1497-bp fragment), both flanked with the *trpC* terminator at the 3' end, were amplified from plasmids p1783-1 and pRHN1 with primer pairs GFP-f/pRS426GFPprev and Dsred-f/pRS426GFPprev, respectively. Some of the primers exhibited at least 29-bp overhangs to the neighboring regions for homologous recombination reactions in *S. cerevisiae* (Colot et al. 2006). All fragments were subcloned into the *XhoI*-linearized vector pRSnat and resulted in C-terminal EGFP- or DsRED-tagged versions of SmNBR1 in plasmid pSmnbr1-egfp and pSmnbr1-Dsred, respectively (Table 3). To analyze different truncated variants of SmNBR1 the following plasmids were constructed according to the full-length version, which differ just in the coding region achieved by using specific primers and pSmnbr1-egfp as template DNA. The promoter and coding region for plasmid pSmnbr1-1-418-egfp, encodes the N-terminal region, was amplified using Nbr1-5f/Nbr1-1-418gfp-r (2395-bp fragment). For plasmid pSmnbr1-419-863-egfp, encodes the C-terminal region, the primer

pair Nbr1-419-863f/GFPNbr1r (1384-bp fragment) was used for amplification of the ORF and the *Smnbr1* promoter was amplified with primer pair Nbr1-5f/Nbr1P-r (1020-bp fragment). The version of *Smnbr1* without the LIR motif (pSmnbr1-1-843-egfp) was amplified using Nbr1-5f/Nbr1-LIR-gfp-3r (3661-bp fragment). All mutated versions of *Smnbr1* were also under control of the native promoter and the following primers were used to introduce the different mutations by PCR: Nbr1-Y847A-L850A-r, Nbr1-T843A-f and Nbr1-SAc-r-f1. For overexpression plasmid pccg1-Smnbr1-egfp, the constitutive promoter *ccg1* from *N. crassa* was amplified from plasmid pHAN1 with primer pair pRSccg1/Pccg1-r (950 bp) and connected to the *Smnbr1* coding region and *egfp* with the *trpC* terminator.

For analyzing SmATG8 and SmNBR1 interaction in *S. macrospora* via Bimolecular Fluorescence Complementation (BiFC) assays recombinant plasmids pRS-YN (hyg) pRS-YC (nat) were generated encoding the N- or C-terminus of the yellow fluorescence protein (YFP-N or YFP-C) under the control of the constitutive *gpd* promoter and the *trpC* terminator of *A. nidulans*. To amplify *yfp-n* or *yfp-c* the vectors pEYFP-N and pEYFP-C were used as templates with primer pair pRS426GPDf2/pRS426GFPprev. The fragments of 2155 bp (*yfp-n*) and 1978 bp (*yfp-c*) were introduced in the *XhoI*-hydrolyzed pRS<sub>hyg</sub> and pRS<sub>nat</sub> vector by homologous recombination in yeast resulting in vectors pRS-YN and pRS-YC, respectively. The *Smatg8* coding sequence was amplified with primer pair Atg8-YN-f/Atg8-YN-r from gDNA (558-bp fragment) and fused it after *yfp-n* in the *SpeI*-hydrolyzed vector pRS-YN (hyg) by ligation. The gDNA sequence of the coding region of *Smnbr1* was amplified with primers Nbr1-YC-f/Nbr1-YC-r (2738-bp fragment) and fused in front of *yfp-c* in the *NotI*-hydrolyzed vector pRS-YC (nat). Both plasmids were introduced in *S. macrospora* wild type strain.

### 2.2.7.2 Plasmid construction of DsRED-tagged *H. sapiens* NBR1 protein

To express the *H. sapiens nbr1* gene in the *S. macrospora*  $\Delta$ Smnbr1 strain, plasmid pHsnbr1-Dsred was constructed expressing *Dsred* C-terminal of *Hsnbr1* gene under the control of the *S. macrospora Smnbr1* promoter. First, the *Hsnbr1* cDNA was amplified from plasmid pOTB7 using primer pair Hsnbr1-f/dsred-Hsnbr1-r carrying 29-bp overhangs either to the *Smnbr1* promoter region or the *Dsred* (2868-bp fragment). The *Smnbr1* promoter region was amplified from gDNA with primer pair Nbr1-5f/Nbr1P-r and resulted in a 1020-bp fragment with 29-bp overhang to the pRS<sub>nat</sub> vector. The *Dsred* flanked with the *trpC* terminator at the 3' end (1497-bp fragment), was amplified from plasmid pRHN1 with primer pair Dsred-f/pRS426GFPprev. All fragments were subcloned into the *XhoI*-linearized vector pRS<sub>nat</sub> by

homologous recombination in yeast. Subsequently, the  $\Delta$ Smnbr1 strain was transformed with the plasmid pHsnbr1-Dsred (2.2.2) and analyzed for complementation ability.

### 2.2.7.3 Plasmid construction of EGFP-tagged ribosomal proteins

To analyze ribosomal proteins *in vivo* SmRPL25 and SmRPS19 were C-terminal tagged with EGFP in the same way as described in 2.2.7.1. The native promoter region and ORF of the ribosomal subunit genes *Smrpl25* and *Smrps19* with 29-bp overhangs were amplified from *S. macrospora* wt gDNA with the primer combination Smrpl25-5f/Smrpl25-gfp-r (1734-bp fragment) and Smrps19-5f/Smrps19-gfp-3r (1641-bp fragment). The *egfp* together with *trpC* terminator from *A. nidulans* was amplified from plasmid p1783-1 using primer pair GFP-f/pRS426GFPprev (1540-bp fragment). By homologous recombination in yeast the respective amplicons were cloned into the *XhoI*-linearized pRSnat vector and resulted in plasmids pSmrpl25-egfp and pSmrps19-egfp.

### 2.2.7.4 Plasmid construction of EGFP-tagged peroxisomal proteins

Plasmid pSmpex14-egfp was constructed by homologous recombination in yeast as described in 2.2.7.1. pSmpex14-egfp encodes the peroxisomal membrane protein SmPEX14 C-terminally tagged with EGFP. The fusion gene is under the control of the native promoter and the *trpC* terminator of *A. nidulans*. The *Smpex14* ORF together with its native promoter region was amplified using primers Smpex14-5f/GFPSmpex14-r with gDNA as template, which resulted in a 2102-bp fragment with 29-bp overhangs. The *egfp* fragment together with the *trpC* terminator (1540-bp fragment) was amplified using primer pair GFP-f/pRS426GFPprev and plasmid p1783-1 as template.

To generate a plasmid that expresses the prominent Woronin body protein SmHEX1 N-terminally tagged with DsRED under the control of the *trpC* promoter plasmid pDsred-Smhex1 was generated. The *trpC* promoter region was amplified using primer pair hex1-5f/hex1-5r and plasmid p1783-1 as template which resulted in a fragment of 898 bp including 29-bp overhangs. Using pRHN1 as template, the *Dsred* gene was amplified with primers Dsred-f/Dsred-r. The amplicon has a size of 674 bp. The coding and 3'-flanking region of *Smhex1* was amplified from *S. macrospora* gDNA with primer pair hex1-f/hex-3r and results in a fragment of 1610 bp including 29-bp overhangs.

All fragments were combined in the *XhoI*-linearized pRSnat vector by homologous recombination in yeast.

### **2.2.7.5 Light and fluorescence microscopic investigations**

For light and fluorescence microscopic analysis, *S. macrospora* strains were grown on solid medium on top of a piece of cellophane (2 x 2 cm) in petri dishes at 27°C for the indicated hours. Subsequently, the cellophane sheet with the mycelium was put on an object slide, covered with water and a cover slip for microscopic analysis. Microscopic investigations were carried out using an “AxioImager M1 microscope” (Zeiss, Jena, Germany) and images were captured with a “Photometrix CoolSNAP HQ camera” (Roper Scientific, Photometrics, Tucson, USA) and processed with the programs MetaMorph (version 6.3.1; Universal Imaging), ImageJ (Image Processing and Analysis in Java) and Adobe Illustrator (CS2). For the detection of fluorescence the “X-cite 120 PC lamp” (EXFO) was utilized with different filter sets. The “chroma filter set 49002” (exciter ET470/40, emitter ET525/50 and beam splitter T495lpxr) was used to visualize EGFP fluorescence, detection of DsRED was achieved with the “chroma filter set 49005” (exciter ET545/30, emitter ET620/60, beam splitter T570lp) and the “chroma filter set 49003” (exciter ET500/20, emitter ET535/30 and beam splitter T515lp) was used for the detection of YFP. Staining of vacuolar membranes was achieved by applying 50-100 µl of a FM4-64 solution (Invitrogen, F34653; 1 µg/ml in A. dest.) directly on the mycelium and incubation for 15 min. FM4-64 fluorescence was recorded with a “chroma filter set 49005” (exciter ET545/30, emitter ET620/60, beam splitter T570lp). When indicated, vacuoles were stained with CMAC (7-amino-4-chloromethylcoumarin, CellTracker Blue; Invitrogen C-2110; stock solution 10 mM in DMSO diluted to ~10 µM in A. dest.) and recorded with “chroma filter set 49000” (exciter D350/50, emitter ET560/50 and beam splitter T400lp). To stain nuclei 100-200 µl of a DAPI (AppliChem, A1001) solution was applied to the mycelium and recorded with “chroma filter set 49000” (exciter D350/50, emitter ET560/50 and beam splitter T400lp). For this, DAPI was dissolved in A. dest. to a final concentration of 1 mg/ml. This stock solution was then diluted with methanol to a concentration of 1 µg/ml.

### **2.2.8 Protein investigations**

#### **2.2.8.1 Protein preparation from *S. macrospora***

To extract proteins from fungal mycelium the strains were inoculated in liquid BMM medium and grown for 3 days. The cell material was filtered with tissues, dried and grounded in a mortar with liquid nitrogen. The cells were lysed in the “Tissue Lyser” (Qiagen) by 30 Hz for 3 min, with the help from ~200 µl glass beads (Ø 0.25-0.5 mm) and cold lysis buffer (560 µl/g mycelium powder). The samples were separated from the cell debris at 13000 rpm and 4°C in

a pre-cooled centrifuge for 15 min and were directly mixed with 5x SDS-PAGE loading dye to get a 1x dilution and heated at 95°C for 15 min for denaturation of the proteins (Laemmli, 1970). For the phosphorylation assay cell lysate was treated with phosphatase inhibitor cocktail as described by the manufacturer or 47 µl cell lysate were treated with 1 µl phosphatase puffer, 1 µl MnCl<sub>2</sub> and 1 µl lambda Phosphatase and incubated at 30°C for 1 h.

### **2.2.8.2 Co-immunoprecipitation (Co-IP)**

For Co-IP experiments the plasmids pSmnbr1-Dsred and pRS-egfp-Smatg8 were co-transformed into the *S. macrospora* wild type strain. Additionally, the complementation strain  $\Delta$ Smnbr1::Smnbr1-Dsred<sup>ect</sup> was constructed and used as control in this experiment as well as the already existing strain  $\Delta$ Smatg8::egfp-Smatg8<sup>ect</sup> (Voigt and Pöggeler 2013a). For interaction studies of ribosomal proteins and SmNBR1 a wild type strain was used expressing SmNBR1-DsRED together with either SmRPL25-EGFP or SmRPS19-EGFP. As control, wild type strains expressing only SmRPL25-EGFP or SmRPS19-EGFP were used. The crude extracts were prepared as described in 2.2.8.1 and aliquots of 1 ml were incubated at 4°C for 1 h on a rotation device with 3 µl monoclonal rat anti-EGFP (Chromotek 3H9 029762) or monoclonal rabbit anti-RFP (GeneScript A00682) antibody. The antigen-antibody complexes were recovered by adding protein A sepharose CL-4B beads (GE Healthcare Life Science, 17-0780-01) and incubated at 4°C for an additional hour on a rotation device. Afterwards, the beads-lysate-mixtures were centrifuged for 2 min at 2000 rpm and washed two times with dilution buffer. The samples were mixed with 5x SDS-PAGE loading dye to get a 1x dilution and boiled for 15 min at 95°C. The preparation of SDS-PAGE, Western blotting and detection of the fusion proteins was done as described in 2.2.8.4 and 2.2.8.5.

### **2.2.8.3 Protein preparation from *S. cerevisiae***

To verify expression of proteins (AD- and BD-fusion proteins) of *S. cerevisiae*, yeast cell cultures were grown at 30°C to midlog phase (OD<sub>600</sub> 0.8). Harvested cells were washed in 500 µl ice-cold buffer b and lysed with glass beads (Ø 0.25-0.5 mm) in 500 µl of buffer b+, and protein extracts were obtained via centrifugation at 13000 rpm for 15 min. Proteins were denatured in 5x SDS-PAGE loading dye at 95°C for 15 min. The whole protein extracts were separated by SDS-PAGE using a 12 % gel.

### **2.2.8.4 Denaturing SDS-polyacrylamide gel electrophoresis (SDS-PAGE)**

12 or 15 %-SDS gels (12 % is representative shown in Table 6) were casted in a “Mini-PROTEAN® Tetra Cell” (Bio-Rad, Germany) and the chamber was filled with 1x SDS-PAGE

running buffer. Once the samples were loaded the electric field of 80 V was applied and after the proteins passed the stacking gel, the voltage was increased to 140 V. For every run a protein standard (PAGERULER™ Prestained Protein Ladder) was used. After protein separation, the gel was further used for a Western blot on a nitrocellulose membrane.

**Table 6: Composition of SDS-polyacrylamide gels.**

Components for one gel	12 % acrylamide separation gel [ml]	5 % acrylamide stacking gel [ml]
Rotiphorese Gel 40	2.25	0.188
1.5 M Tris/HCl pH 8.8	1.87	-
0.5 M Tris/HCl pH 6.8	-	0.5
20 % (w/v) SDS	0.037	0.02
A. dest.	3.3	1.3
TEMED	0.006	0.0017
10 % (w/v) APS	0.05	0.013

### 2.2.8.5 Western blot, hybridization and detection reaction

For Western blots, separated proteins were transferred from the SDS-PAGE gels onto nitrocellulose membranes using 1x transfer buffer and a Mini Trans-Blot® Cell device as described by the manufacturer (Biorad) (Towbin et al. 1979). After the transfer, the membrane was incubated for 1 h in 30 ml skim milk blocking solution. The membrane was with the primary antibody solved in blocking solution incubated for at least 2 h at RT or overnight at 4°C. Afterwards, the antibody was removed and the membrane was washed three times for 15 min with 1x TBST before the membrane was incubated with the secondary antibody diluted in blocking solution. After 1 h the secondary antibody was removed and the membrane underwent a second washing step.

Immune detection of the proteins containing an EGFP or DsRED tag was achieved using the following antibodies: monoclonal rat anti-EGFP antibody (1:4000, Chromotek 3H9 029762) and a secondary HRP-linked goat anti-rat antibody (1:5500, Invitrogen 62-9520); monoclonal rabbit anti-RFP (1:2000, GeneScript A00682) and the appropriate secondary goat anti-rabbit antibody (1:2000, Life Technologies G21234). The immune detection of actin was performed with a monoclonal mouse anti-actin antibody (Novus, NB100-74340, 1:3000) and the secondary HRP-linked goat anti-mouse antibody (Dianova, 115-035-003, 1:10000).

Immunodetection of aminopeptidase 1 (Ape1) was performed with a polyclonal rabbit anti-Ape1 antibody (kindly provided by M. Thumm, Göttingen, 1:2500) and as secondary antibody HRP-linked anti-rabbit antibody (1:2500, Invitrogen G21234) was used. Ubiquitin was detected with monoclonal mouse anti-ubiquitin (Millipore, ST1200, 1:1000) antibody and the secondary HRP-linked goat anti-mouse antibody (Dianova, 115-035-003, 1:10000).

SmATG12 and SmATG8 proteins fused to the Gal4-activation domain in the pGADT7 vector were detected using a monoclonal mouse anti-HA antibody (diluted 1:3000, Sigma-Aldrich A2095) and proteins fused to the Gal4-binding domain in the pGBKT7 vector were detected using a monoclonal mouse anti-myc antibody (1:5000, Cell Signaling Technology 2279). Blotting of proteins to the membrane was visualized by staining with ponceau red solution (3 % TCA, 0.2 % ponceau S). The detection of the signals was performed with the Immobilon™ Western HRP Substrate Kit and visualized on chemiluminescence films (Amersham Hyperfilm™ ECL) using an “Optimax X-ray film processor” (PROTEC GmbH & Co. KG, Germany).

#### **2.2.8.6 GFP-Trap experiment and Coomassie staining**

The SmNBR1-EGFP fusion protein was used as bait for the GFP-Trap analysis. Protein extracts of the strains  $\Delta$ Smnbr1::Smnbr1-egfp<sup>ect</sup>, containing the plasmid pSmnbr1-egfp expressing SmNBR1 C-terminally tagged with EGFP, and as control the wild type strain containing plasmid p1783-1 encoding the EGFP-tag under the control of the *A. nidulans* *gpd* promotor and *trpC* terminator, were prepared as described in 2.2.8.3 with an additional centrifugation step of 30 min for 13000 rpm to get the protein lysate. 20  $\mu$ l GFP-Trap agarose beads were calibrated by washing them three times in cold 500  $\mu$ l dilution buffer at 3000 rpm and 4°C for 2 min. 1 ml of the protein extracts was added to the beads and incubated at 4°C for 3 h in a spinning wheel to evoke end-over-end mixing. After centrifugation at 2000 rpm and 4°C for 2 min, the supernatant was discarded and the pellet was washed and centrifuged two times with cold 500  $\mu$ l dilution buffer.

Trap beads were resuspended in 40  $\mu$ l 5x SDS-PAGE loading dye to get a 1x dilution and boiled at 95°C for 15 min. After separation of the proteins by SDS-PAGE (2.2.8.4) the gel was stained with colloidal Coomassie follows (Kang et al. 2002). For Coomassie staining the gel was shaken in fixing solution for 1 h and subsequently washed twice with H<sub>2</sub>O for 10 min. Afterwards, the gel was incubated overnight in Coomassie staining solution. To remove Coomassie particles after staining the gel was washed with H<sub>2</sub>O. For destaining, the SDS-Gel was incubated in fixing solution and subsequently washed twice with H<sub>2</sub>O.

### 2.2.8.7 Trypsin digest of proteins

Protein digestion with trypsin was performed according to Shevchenko et al. (1996). Whole lanes of Coomassie stained gels were cut into 10 small pieces of approximately 2 mm and transferred into 1.5 ml Protein LoBind Tubes (0030108116, Eppendorf, Hamburg, Germany). 30  $\mu$ l acetonitrile were added to the gel pieces. The volume was adjusted to the amount of gel, since the gel pieces should be fully covered with acetonitrile. The samples were incubated for 10 min under constant shaking before the acetonitrile was removed. The gel pieces were dried for 10 min in the SpeedVac concentrator (Eppendorf concentrator 5301). 150  $\mu$ l 10 mM DTT were added and the samples were incubated at 56°C for 1 h. The DTT solution was removed and the gel pieces were covered with 150  $\mu$ l 55 mM iodoacetamide dissolved in 100 mM  $\text{NH}_4\text{HCO}_3$  followed by incubation for 45 min in the dark. The iodoacetamide was removed and the gel pieces were washed with 150  $\mu$ l 100 mM  $\text{NH}_4\text{HCO}_3$  for 10 min after removing 150  $\mu$ l acetonitrile were added and incubated for 10 min. Both washing steps were performed under constant shaking and repeated twice. The gel pieces were dried in the SpeedVac concentrator for 10 min and subsequently covered with sufficient trypsin digestion buffer. The samples were incubated for 45 min on ice and excessive trypsin digestion buffer was removed. The gel pieces were covered with 25 mM  $\text{NH}_4\text{HCO}_3$ , and the samples were incubated overnight at 37°C. The liquid was collected by centrifugation at 13000 rpm and transferred to a fresh 1.5 ml Protein LoBind Tube. Peptides were extracted from the gel by the sequential incubation with 20 mM  $\text{NH}_4\text{HCO}_3$  for 10 min and three times with a 50 % acetonitrile 5 % formic acid mixture for each 20 min. Incubations were performed under constant shaking and the liquid was collected by centrifugation and transferred into the new LoBind Tube after each step. The collected supernatant was completely dried in the SpeedVac concentrator. The peptide pellet was resolved in 20  $\mu$ l sample buffer (2-5 % acetonitrile, 0.1 % formic acid) for further purification. The purification with the C18 stop and go extraction (stage) tips was performed according to Rappsilber et al. (2003). Small disks were obtained from a C18 Solid phase extraction Disk and at least two of them were pushed into a 100-200  $\mu$ l pipette tip on top of each other. The C18 column material was equilibrated with 100  $\mu$ l methanol with 0.1 % formic acid, followed by 100  $\mu$ l 70 % acetonitrile with 0.1 % formic acid and washed twice with 100  $\mu$ l  $\text{H}_2\text{O}$  with 0.1 % formic acid. After the addition of each solvent the stage tips were centrifuged with the help of an adaptor in 2 ml reaction tubes at 13000 rpm for 2 min. The peptide samples were loaded and incubated on the stage tip for 5 min, followed by centrifugation at 4000 rpm for 5 min. To increase the yield, the flow-through was loaded again and the stage tips were centrifuged at

4000 rpm for 5 min once more. The C18 material was washed twice with 100  $\mu$ l H<sub>2</sub>O with 0.1 % formic acid, each time followed by centrifugation at 10000 rpm for 2 min. For peptide elution 60  $\mu$ l 70 % acetonitrile with 0.1 % formic acid were applied onto the column, incubated on the stage tip for 5 min, and centrifuged at 4000 rpm for 5 min. This peptide solution was dried completely in the SpeedVac concentrator and resolved in 20  $\mu$ l of the sample buffer for LC-MS analyses.

#### **2.2.8.8 Liquid chromatography-mass spectrometry analysis (LC/MS)**

LC/MS analysis for protein identification was performed with an “Orbitrap Velos Pro™ Hybrid Ion Trap-Orbitrap mass spectrometer”. 1-5  $\mu$ l of peptide solutions were loaded and washed on an Acclaim® PepMAP 100 pre-column (164564, 100  $\mu$ m x 2 cm, C18, 3 $\mu$ m, 100 Å, Thermo Fisher Scientific) with 100 % loading solvent A (98 % H<sub>2</sub>O, 2 % acetonitrile, 0.07 % trifluoroacetic acid (TFA)) at a flow rate of 25  $\mu$ l/min for 6 min. Peptides were separated by reverse phase chromatography on an Acclaim® PepMAP RSLC column (75  $\mu$ m x 25 cm, (164536) or 50 cm (164540), C18, 3  $\mu$ m, 100 Å, Thermo Fisher Scientific) with a gradient from 98% solvent A (H<sub>2</sub>O, 0.1 % formic acid) and 2 % solvent B (80 % acetonitrile, 20 % H<sub>2</sub>O, 0.1 % formic acid) to 42 % solvent B for 95 min and to 65 % solvent B for the following 26 min at a flow rate of 300 nl/min. Peptides eluting from the chromatographic column were on-line ionized by nanoelectrospray at 2.4 kV with the Nanospray Flex Ion Source (Thermo Fisher Scientific). Full scans of the ionized peptides were recorded within the Orbitrap FT analyzer of the mass spectrometer using a mass range of 300-1850 m/z at a resolution of 30000. Collision induced dissociation (CID) fragmentation of data-dependent top-ten peptides was performed with the “LTQ Velos Pro linear ion trap”. For data acquisition and programming the XCalibur 2.2 software (Thermo Fisher Scientific) was used. Protein identification was performed with the MaxQuant 1.5.1.0 software (Cox et al. 2011) using a *S. macrospora*-specific peptide database (Nowrousian et al. 2010). The mass tolerance was 4.5 ppm for precursor ions and 0.5 Da for fragment ions. The decoy mode was revert with a false discovery rate of 0.01. Further, data processing and statistical analysis were performed with the Perseus 1.5.1.0 software. A t-test was performed and only significant results were further considered. Database searches were performed with the SequestHT and Mascot search algorithms against a *S. macrospora*-specific protein database (Nowrousian et al. 2010). The digestion mode was set to trypsin and the maximum of missed cleavage sites to two. The decoy mode was revert with a false discovery rate of 0.01.

### 2.2.8.9 Yeast-two hybrid (Y2H) interaction studies

The Y2H assay allows the investigation of the interaction of two proteins in yeast (Fields and Song 1989). Yeast cells were transformed with Y2H vectors that derived from pGADT7 and the pGBKT7 vectors (Clontech) which provided the *LEU2* (yeast strain AH109) or *TRP1* (yeast strain Y187) synthesis genes for the selection of transformed cells. Plasmids pGADT7 encoded the prey proteins, fused to the Gal4-activation domain, while pGBKT7 coded for the bait proteins, fused to the binding domain of the Gal4-transcription factor. The interaction of prey and bait protein activated the expression of reporter genes (*ADE2*, *HIS3* and *lacZ*) controlled by the Gal4-transcription factor. For detection of the proteins in Western blot pGADT7 vector encodes for a HA-tag and pGBKT7 for a myc tag.

The prey plasmid pAD-Smnbr1 was constructed by ligation. For this the cDNA fragment of *Smnbr1* was amplified using primer pair Nbr1-t1/Nbr1-t2, by this *EcoRI*-restriction sites were introduced at both ends. The resulting fragment was ligated into *EcoRI*-linearized vector pGADT7. To generate the bait vector pBD-Smnbr1, the same *Smnbr1* amplicon with *EcoRI* overhangs was cloned into the *EcoRI*-linearized vector pGBKT7. The different variants of *Smnbr1* were amplified with overhangs to this backbone vector as mentioned hereafter: fragment *Smnbr1* (1-843) with primers ADNbr1-(HR)-f/ADNbr1-LIR(HR)-r (2562 bp), *Smnbr1* (1-418) with primers ADNbr1-(HR)-f/ADNbr1-1-418(HR)-r (1315 bp) and *Smnbr1* (419-863) with primers ADNbr1-419-863(HR)-f/ADNbr1-(HR)-r. Further, the mutations *Smnbr1* (T<sup>843</sup>A), *Smnbr1* (Y<sup>847</sup>A L<sup>850</sup>A), *Smnbr1* (T<sup>843</sup>A Y<sup>847</sup>A L<sup>850</sup>A) were introduced in the *Smnbr1* full-length fragment with primers Nbr1-T843A-f, Nbr1-Y847A-L850A-r (*Smnbr1* (T<sup>843</sup>A) served as template), and for *Smnbr1* (S<sup>793</sup>A), *Smnbr1* (S<sup>793</sup>A S<sup>804</sup>A S<sup>808</sup>A) with primers Nbr1-SAc-f2 and Nbr1-SAc-f1, respectively, in a second PCR cycle. Afterwards, the fragments were cloned into *EcoRI*-hydrolyzed pGADT7 vector by homologous recombination in yeast (Colot et al. 2006) (2.2.7.1). Construction of plasmids pAD-Smatg8 and pBD-Smatg8 have been previously described in Voigt and Pöggeler (2013a).

The prey plasmid pAD-Smatg12 was constructed by cloning an amplified cDNA fragment of *Smatg12* together with restriction sites *NdeI* and *EcoRI* using primer pair Atg12\_Hf2/Atg12\_Hr2, into *NdeI/EcoRI*-linearized vector pGADT7. To generate the bait vector pBD-Smatg12, the *Smatg12* amplicon amplified with primer pair Atg12\_Hf/Atg12\_Hr with *EcoRI* and *SalI* overhangs was cloned into the *EcoRI/SalI*-linearized vector pGBKT7. Plasmids pAD-Smatg7 and pBD-Smatg7 were constructed by amplifying an *Smatg7* cDNA fragment using primer pair Atg7\_Hf/Atg7\_Hr, which was ligated in *EcoRI/HindIII*-hydrolyzed

pGADT7/pGBKT7 vectors, respectively. Plasmids pAD-Smatg3 and pBD-Smatg3 were obtained by amplifying *Smatg3* with primer pair Atg3\_Hf/Atg3\_Hr from *S. macrospora* wt cDNA and inserting it as *NdeI/EcoRI*-fragment into appropriate hydrolyzed vectors pGADT7 and pGBKT7, respectively. All ligation reactions were conducted with T4-DNA ligase and the setup was as described in 2.2.4.2. Plasmids pAD-Smrpl25 and pBD-Smrpl25 were generated by homologous recombination in yeast. For this, *Smrpl25* cDNA was amplified using primer pair AD-rpl25-f/AD-rpl25-r or BD-rpl25-f/BD-rpl25-r to get a fragment of 612 bp including 29-bp overhangs, which was co-transformed with *EcoRI*-hydrolyzed pGADT7 and pGBKT7 vector into yeast, respectively. Plasmids pAD-Smrps19 and pBD-Smrps19 were constructed by amplifying a cDNA fragment of 470 bp using primer pair Smrps19-c5/Smrps19-c3 for the pAD-Smrps19 and Smrps19-c5/Smrps19-c3-BamHI for the pBD-Smrps19 construct. The fragments were ligated in *EcoRI/PstI*-hydrolyzed pGADT7 or *EcoRI/BamHI*-hydrolyzed pGBKT7 vector.

*S. cerevisiae* strains AH109 and Y187 were used for yeast-two hybrid experiments. For yeast-two hybrid analysis Mat  $\alpha$  strain Y187 was transformed with bait plasmids pGBKT7, pBD-Smatg8, pBD-Smnbr1, pBD-Smatg12, pBD-Smatg3, pBD-Smatg7, pBD-Smrpl25 or pBD-Smrps19 and transformants were selected for tryptophan prototrophy, whereas Mat  $a$  strain AH109 was transformed with prey plasmids pGADT7, pAD-ranBPM, pAD-Smatg8, pAD-Smatg12, pAD-Smatg3, pAD-Smatg7, pAD-Smrpl25, pBD-Smrps19, pAD-Smnbr1, pAD-Smnbr1(1-418), pAD-Smnbr1(419-863), pAD-Smnbr1(1-843), pAD-Smnbr1(Y<sup>847</sup>A L<sup>850</sup>A), pAD-Smnbr1(T<sup>843</sup>A), pAD-Smnbr1(T<sup>843</sup>A Y<sup>847</sup>A L<sup>850</sup>A), pAD-Smnbr1(S<sup>793</sup>A), pAD-Smnbr1(S<sup>793</sup>A S<sup>804</sup>A S<sup>808</sup>A) and transformants were selected for leucine prototrophy. Recombinant AH109 and Y187 strains were mated and selected on solid SD minimal medium lacking both, tryptophan and leucine. Alternatively, both plasmids were co-transformed into yeast strain AH109. Interaction of the bait and prey fusion constructs was confirmed by drop dilution assays and growth on selective SD minimal medium lacking histidine and adenine. Therefore, cells grown to log phase in liquid SD minimal medium without leucine and tryptophan were diluted to an optical density (OD) of 0.1. From this main dilution, 20  $\mu$ l were spotted in a 1:10 dilution series onto selective SD plates, which were incubated at 30°C for five days. Yeast growth was visualized using a “Digital Microscope VHX-500F” (Keyence, Germany).

The PXG (pellet X-Gal) assay was performed and modified according to Mückli and Auerbach (2004). Yeast cultures were grown to OD<sub>600</sub> 0.8 and the cell pellet was solved in 100  $\mu$ l water and lysed with glass beads ( $\varnothing$  0.25-0.5 mm) in a “Tissue Lyser” (Qiagen) by 30 Hz for 3 min.

To 20  $\mu$ l of the cell pellet 100  $\mu$ l PBS buffer with 500  $\mu$ g/ml X-Gal and 0.05 % (v/v)  $\beta$ -mercaptoethanol were added and incubated at RT for up to 12 h. The  $\beta$ -galactosidase enzymatic activity was monitored by recording the color development with a 96-well microplate reader (Tecan Infinite 200).

### **2.2.9 Yeast complementation and Ape1 maturation assay**

To analyze functional conservation of *atg12* in *S. macrospora* and *S. cerevisiae* the aminopeptidase 1 (Ape1) maturation assay was carried out as described by Harding et al. (1995) and Voigt and Pöggeler (2013a). To express the *Smatg12* cDNA under the control of the yeast *MET25* promoter, a *MET25-Smatg12* fusion construct was generated in pRS-met25-Smatg12. cDNA of *S. macrospora* wild type was used as template to amplify *Smatg12* with primer pair Atg12\_Cf/Atg12\_Cr having *SpeI*- and *SalI*-restriction sites, respectively. The resulting 480-bp *Smatg12* fragment was cloned into the *SpeI/SalI*-hydrolyzed plasmid pRS426-met25 (Mumberg et al. 1994). Plasmid pRS-met25-Scatg12 was generated by cloning a 561-bp *Scatg12* fragment amplified with primer pair Scatg12-f/Scatg12-r having *SpeI*- and *EcoRI*-restriction sites from *S. cerevisiae* BY4741 wt gDNA into the *EcoRI/SpeI*-hydrolyzed plasmid pRS426-met25. Afterwards, yeast strain Y03357 (*atg12* $\Delta$ ) was transformed with plasmids pRS-met25-Smatg12 and pRS-met25-Scatg12. As negative controls, the *S. cerevisiae* wt strain BY4741 as well as the yeast *atg12* $\Delta$  deletion strain, were transformed with the empty vector pRS426-met25. To test yeast transformants for their ability to rescue the Ape1 processing in the *atg12* $\Delta$  mutant, cells were grown overnight in SD minimal medium and adjusted to OD<sub>600</sub> = 1. One set of cells was used for protein extraction, while another set was grown for four hours in SD minimal medium lacking nitrogen (SD-N) to induce amino-acid starvation and, in turn, autophagy in *S. cerevisiae* (Harding et al. 1995). For protein extraction yeast cells were centrifuged (4000 rpm, 10 min, 4°C) and washed with cold water and resuspended in 1 ml A. dest.. Subsequently, cell suspension was mixed with 150  $\mu$ l lysis buffer (*S. cerevisiae*) and incubated for 10 min on ice. 50 % TCA was added and the suspension was incubated for additional 10 min on ice. After centrifugation (4000 rpm, 10 min, 4°C), the cell pellet was washed twice with acetone (-20°C) and resuspended in 100  $\mu$ l 5x SDS-PAGE loading dye (Laemmli 1970) and incubated at 95°C for 10 min. Samples were centrifuged at 4000 rpm for 10 min at 4°C before separating 10-15  $\mu$ l of the protein solution by 12 % SDS-PAGE, followed by blotting onto a nitrocellulose membrane as described in 2.2.8.4. Immunodetection of aminopeptidase 1 (Ape1) was performed with a polyclonal rabbit anti-Ape1 antibody (2.2.8.5).

### **2.3 Measures of safety**

Genetic engineering experiments of security level 1 have been conducted according to the guide lines of the genetic engineering law (GenTG) stated on 16.12.1993 (recently altered by Art. 12 G v. 29.7.2009 I 2542).

### 3. Results

#### 3.1 Characterization of the autophagy-associated protein SmATG12 in *S. macrospora*

##### 3.1.1 Identification of a *S. macrospora* ATG12 homolog as an interaction partner of SmATG7 and SmATG3

The ubiquitin-like gene *Smatg12* is one of the conserved core autophagy genes. Its function was not yet analyzed in *S. macrospora*. A BLASTP search of predicted *S. macrospora* proteins (Nowrousian et al. 2010) using *S. cerevisiae* ATG12 (P38316) as a query sequence identified a protein of 215 amino acids encoded by the ORF *SMAC\_06998* as the top hit ( $3e^{-13}$ ). Compared with ATG12 proteins from other organisms, the protein *SMAC\_06998* has an extended C-terminal region but no glycine residue at the C-terminus. Automatic annotation predicted two introns in *SMAC\_06998* (data not shown); however, RT-PCR amplification with primer pair 06998\_f/06998\_r and sequencing confirmed only splicing of the first intron, which leads to an earlier stop codon. The amplified cDNA encodes a protein of 159 amino acids with a conserved C-terminal glycine that shares a significant level of sequence similarity with ATG12 proteins of plants and animals that also have a conserved glycine at the C-terminus (Figure 8). The *S. macrospora* ATG12 homolog shares 81 % and 50 % identity to the previously described ATG12 proteins from *N. crassa* and *Magnaporthe oryzae* (Kershaw and Talbot 2009; Chinnici et al. 2014), but only about 20 % identity with homologs from *S. cerevisiae*, plants and animals. However, most of the residues involved in non-covalent interactions between ATG12 and ATG5 (Supplement 1), binding and conjugation of ATG3 (Supplement 2), or binding of ATG8 in the *S. cerevisiae* and the human ATG12 homologs are conserved in the *S. macrospora* ATG12 (Radoshevich et al. 2010; Metlagel et al. 2013; Noda et al. 2013; Otomo et al. 2013; Kaufmann et al. 2014). Several residues within the BH3 domain of ATG12 homologs from mammals and non-mammalian vertebrates are also conserved. Similar to the *S. cerevisiae* and other fungal ATG12 homologs, a conserved aspartic acid residue (equivalent to D64 in human ATG12) that is required for binding of anti-apoptotic proteins, is replaced by a serine residue at position 82 in the *S. macrospora* protein (Figure 8) (Rubinstein et al. 2011).

## Results

**Figure 8: Multiple-sequence alignment of ATG12 orthologs from fungi, plants and animals.**

ClustalX alignment was created using the following sequences: Smac, *Sordaria macrospora* (XP\_003349162.1), excluding 56 C-terminal amino acids; Ncra, *Neurospora crassa* (Q7S083.1); Pans, *Podospora anserina*, (XP\_001906089.1); Cglo, *Chaetomium globosum* (Q2GSG9.2); Mory, *Magnaporthe oryzae* (XP\_368646.1); Anid, *Aspergillus nidulans* (Q5BCH0.2); Pchr, *Penicillium chrysogenum* (XP\_002557636.1); Celg, *Caenorhabditis elegans* (CCD61524.1); Hsap, *Homo sapiens* (NP\_004698.3); Dmel, *Drosophila melanogaster* (NP\_648551.39); AthaB, *Arabidopsis thaliana* (Q9LVK3.1); AthaA, *A. thaliana* (Q8S924.1); Scer, *Saccharomyces cerevisiae* (P38316). Identical amino acids, which are conserved in all proteins, are shaded in black; residues conserved in at least 10 of 13 sequences are shaded in dark grey and residues conserved in at least eight sequences are shaded in light grey. The conserved C-terminal glycine residue for the covalent linkage to ATG5 and the conserved phenylalanine residue corresponding to Phe154 in the *S. cerevisiae* Atg12 is labeled in red (Hanada and Ohsumi 2005), amino acids important for non-covalent interactions between ATG12 and ATG5 in *S. cerevisiae* according to Noda et al. (2013) are marked by asterisks. Non-covalent contacts between ATG12 and ATG5 identified in the human homologs according to Otomo et al. (2013) are marked by black squares. The red bar represents the turn-loop-alpha helix 2 segment (Asn105-Phe123 of the human ATG12) which is associated with the interaction surface of ATG5 (Otomo et al. 2013). White squares mark residues of the human ATG12, which are important for binding of ATG3 (Metlagel et al. 2013); #, indicates residues of the non-canonical AIM of ATG12 involved in interaction with ATG8 (Kaufmann et al. 2014). The region of the BH3 domain identified in the human ATG12 homolog is indicated and the conserved aspartic acid residue is indicated in green. Amino-acid identity in % is given at the right margin.

In *S. cerevisiae*, direct protein-protein interactions between the UBL protein Atg12 and both E1/E2-like enzymes Atg7 and Atg3 have been reported (Yamazaki-Sato et al. 2003; Metlagel et al. 2013; Otomo et al. 2013). To confirm that SmATG12 can interact with SmATG7 (*SMAC\_06539*) and SmATG3, yeast-two hybrid analyses were performed after cloning of *Smatg12*, *Smatg7* and *Smatg3* (*SMAC\_05399*) cDNAs into prey and bait vectors pGBKT7 and pGADT7. The resulting bait and prey plasmids were transformed into yeast strains Y187 and AH109, respectively, which were then mated, or both plasmids were co-transformed into strain AH109. Transactivation of pBD-derivatives was tested by mating with the AH109 strain carrying the empty vector pGADT7 (data not shown). As a positive control and to confirm expression of the proteins encoded by the bait plasmids, strains were mated with yeast strain AH109 containing pAD-ranBPM. RanBPM directly interacts with the Gal4-binding domain, which provides a method for confirming that the gene cloned into the bait vector is expressed appropriately (Tucker et al. 2009). The two-hybrid experiment clearly demonstrated an interaction between SmATG12 and both SmATG3 and SmATG7 (Figure 9A+B).

**Figure 9: Yeast-two hybrid interaction of SmATG12 with SmATG7, SmATG3 and SmATG8.**

Full-length cDNAs of *Smatg12*, *Smatg7* and *Smatg3* were used to generate Gal4-DNA binding domain (BD) and activation domain (AD) plasmids. *Smatg8* two-hybrid vectors were previously described in Voigt and Pöggeler (2013a). To select for the presence of both plasmids 20  $\mu$ l of cells were spotted in serial dilutions on SD medium lacking tryptophan and leucine (SD -Trp, -Leu) or to verify the interactions of the proteins on medium lacking additionally histidine or adenine (SD -Trp, -Leu, -His/-Ade). (A) SmATG12 and SmATG7 interacted only when SmATG7 was expressed as Gal4-BD fusion protein. (B) SmATG12 and SmATG3 interacted with each other as bait and prey proteins, respectively. (C) SmATG8 did not interact with SmATG12. Transformants carrying a bait plasmid and pAD-ranBPM (Tucker et al. 2009) were used to confirm the appropriate expression of the bait proteins. Strains carrying empty plasmids pGADT7 and pGBKT7 served as negative control (A). Plates were incubated for 3-5 days at 30°C.

Nevertheless, SmATG12 and SmATG7 interacted only when SmATG7 was expressed as a Gal4-BD fusion protein (Figure 9A). Recently, Kaufmann et al. (2014) demonstrated that the yeast Atg8-PE can directly interact with Atg12 via a non-canonical AIM in Atg12. However, interaction of SmATG12 and SmATG8 could not be demonstrated in the yeast-two hybrid system (Figure 9C), although expression of SmATG8 and SmATG12 in yeast was verified by Western-blot analysis (Figure 10).

**Figure 10: Verification of the protein expression of SmATG12 and SmATG8 in yeast-two hybrid transformants.**

The proteins SmATG12 and SmATG8 fused to the Gal4-activation domain (AD) were detected with an anti-HA antibody and those fused to the Gal4-binding domain (BD) with an anti-myc antibody. Transformants carrying either a single vector or both vectors were used as positive and negative controls, respectively.

Furthermore, in this study we tested the functional conservation of SmATG12 and its yeast counterpart by a yeast complementation assay with the *Smatg12* cDNA expressed under the control of a *MET25* promoter in an *S. cerevisiae* *atg12*Δ null mutant. Rescue of autophagy in the *S. cerevisiae* mutant was monitored using an aminopeptidase I (Ape1) maturation assay based on the autophagy-dependent maturation of the precursor proaminopeptidase I (prApe1) to the mature enzyme (mApe1) (Harding et al. 1995). In *S. cerevisiae*, Ape1 maturation relies on an intact UBL protein Atg12. However, the *Smatg12* gene was unable to complement the yeast *atg12*Δ mutant (Figure 11).

In *S. cerevisiae*, Ape1 is delivered by the cytoplasm-to-vacuole targeting pathway to the vacuole. So far, it is not clear if this pathway exists in *S. macrospora*. In addition, we therefore monitored autophagy in the complemented mutant *atg12*Δ by the GFP-ScAtg8 proteolysis assay. When GFP-ScAtg8 is delivered to the lumen of the vacuole, the Atg8 part of the fusion protein is sensitive to degradation, whereas the GFP moiety is relative resistant to hydrolysis.

**Figure 11: Complementation of the *S. cerevisiae* atg12Δ autophagy mutant with the *S. macrospora* *Smatg12* gene.**

Complementation of the yeast strain atg12Δ with *Smatg12* under the control of the yeast *MET25* promoter (pRS-met25-*Smatg12*) was analyzed using an aminopeptidase 1 (Ape1) maturation assay (Harding et al. 1995). As positive controls, the *S. cerevisiae* wt strain BY4741 was transformed with the empty plasmid pRS426-met25 or atg12Δ was transformed with the yeast plasmid pRS-met25-*Scatg12* expressing the endogenous *Scatg12* gene. *S. cerevisiae* atg12Δ transformed with the empty vector pRS426-met25 served as negative control. Total cell extracts of an equal amount of yeast cells of a growing culture under non-starvation conditions (-) or 4h nitrogen starved cells (+) were separated on 15 % SDS-PAGE. After blotting, nitrocellulose membranes were probed with an anti-Ape1 antibody. Anti-actin antibody was used as loading control. prApe1, Ape1 precursor; mApe1, mature Ape1.

In a Western blot with an anti-GFP antibody the appearance of free GFP can be used to monitor delivery of autophagosomal membranes to the vacuole (Klionsky et al. 2012). The assay revealed that also no processing of GFP-ScAtg8 occurred in the atg12Δ yeast strain complemented with the *Smatg12* gene (Figure 12).

**Figure 12: Proteolytic cleavage of GFP-ScATG8.**

The wt (BY4741), atg12Δ and the putative complementation strains atg12Δ+pRS-met25-*Scatg12* and atg12Δ+pRS-met25-*Smatg12* were transformed with plasmid pRS315-GFP-ScAtg8. The GFP-ScAtg8 protein was detected with an anti-GFP antibody and has an expected size of 40 kDa. The proteolytic cleavage of the GFP-ScAtg8 fusion protein can be detected by the free GFP signal at 27 kDa.

### 3.1.2 Deletion of *Smatg12* impairs vegetative growth and fruiting-body development

To analyze the effect of *Smatg12* on autophagy, vegetative growth and sexual development of *S. macrospora*, a  $\Delta$ *Smatg12* knockout mutant was generated for phenotypic characterization (Figure 13). The *Smatg12* knockout strain was constructed as described in 2.2.6.2. The EGFP-SmATG8 proteolysis assay in the *S. macrospora*  $\Delta$ *Smatg12* mutant revealed that vacuolar degradation of the fusion protein is inhibited, whereas in the complemented  $\Delta$ *Smatg8* strain ( $\Delta$ *Smatg8::egfp-Smatg8<sup>ect</sup>*) proper vacuolar proteolysis of the fusion protein can be observed (Figure 14).

**Figure 13: Construction of a  $\Delta$ *Smatg12* mutant.**

(A) Schematic illustration of the *S. macrospora* *Smatg12* locus *SMAC\_06998* (black arrow) with neighboring genes *SMAC\_06997* and *SMAC\_06999* and the derived  $\Delta$ *Smatg12* knockout locus. Gene replacement was reached by integration of an *hph*-deletion cassette at the respective gene locus (grey arrow) by homologous recombination. The intron is indicated as white box. Positions of primers used for knockout plasmid construction and verification of the successful homologous integration at the *Smatg12* locus are marked with small arrows. Sizes of the corresponding PCR fragments are indicated. *hph*, hygromycin resistance; *PtpC*, *A. nidulans trpC* promoter. (B) PCR analysis for verification of the integration of the *hph*-deletion cassette at the desired *Smatg12* gene locus in comparison to the wt. The positions of primers and expected fragment sizes indicated in (A) could be detected. (C) Southern hybridization for verification of the  $\Delta$ *Smatg12* strain. Genomic DNA from *S. macrospora* wt and the  $\Delta$ *Smatg12* mutant was digested with *Bgl*II and hybridized with the 300-bp probe indicated in (A), which covered the promoter region of *Smatg12*. The expected fragments of 3398 bp for the wt and 4230 bp for the  $\Delta$ *Smatg12* strain could be detected. The scale bar indicates 1 kb.

Although, *Smatg12* cannot complement the *S. cerevisiae* *atg12* $\Delta$  strain, this result suggests, that the isolated gene is an ortholog of the yeast *Scatg12*.

In contrast to the wild type strain and a complemented mutant strain ( $\Delta$ *Smatg12::egfp-Smatg12<sup>ect</sup>*), the mutant  $\Delta$ *Smatg12* did not form mature fruiting bodies when grown on solid SWG fructification medium or under histidine-starvation conditions imposed using the drug 3-aminotriazole (3-AT) (Figure 15A). Prevention of autophagy is known to lead to the impairment of the foraging capability of filamentous ascomycetes (Josefsen et al. 2012), which describes the growth of filamentous fungi over a non-nutritious surface in order to reach nutrient-rich regions. The required nutrients are thought to be provided by autophagy taking place in the basal hyphae of mycelia (Shoji and Craven 2011; Voigt and Pöggeler 2013b; Chinnici et al. 2014).

**Figure 14: EGFP-SmATG8 protein degradation in the  $\Delta$ *Smatg12* strain compared to the corresponding complemented  $\Delta$ *Smatg8::egfp-Smatg8<sup>ect</sup>* strain.**

Protein crude extracts of *S. macrospora* wt, wt::1783-1<sup>ect</sup>,  $\Delta$ *Smatg12::egfp-Smatg8<sup>ect</sup>* and  $\Delta$ *Smatg8::egfp-Smatg8<sup>ect</sup>* strains expressing EGFP or EGFP-SmATG8 were separated on a 12 % SDS-PAGE gel. The Western blot hybridization using an anti-EGFP antibody verified the degradation of the EGFP-SmATG8 fusion protein in the complemented  $\Delta$ *Smatg8* strain by accumulation of free EGFP, whereas in the  $\Delta$ *Smatg12* mutant the EGFP-SmATG8 fusion protein accumulated. Wt and wt::1783-1<sup>ect</sup> were used as controls. Actin was detected as protein loading control.

To analyze the foraging capability of  $\Delta$ *Smatg12*, wild type and the complemented strain ( $\Delta$ *Smatg12::egfp-Smatg12<sup>ect</sup>*), agar plugs were transferred into an empty cell-culture plate and incubated for 5 days at 27°C. While the wild type and the complemented strain underwent extensive mycelial growth,  $\Delta$ *Smatg12* was unable to grow over the inert plastic surface (Figure 15B). In addition, the deletion mutant displayed a significant decrease in growth rate under histidine-starvation conditions imposed by 3-AT (Figure 15C). In the complemented strain the growth defect was only partially complemented in comparison to the wild type, probably due to an ectopic integration of the *egfp*-tagged *Smatg12*. Similarly, a slight growth defect of the complemented mutant could be observed under non-starvation conditions (SWG fructification medium), which might be also explained by ectopic integration of the *egfp*-tagged *Smatg12* wild type copy.

## Results

**Figure 15: Phenotypic characterization of *S. macrospora* wt, *Smatg12* deletion and complementation strain.** (A) Phenotype of wt,  $\Delta$ Smatg12 and rescued strain  $\Delta$ Smatg12::egfp-Smatg12<sup>ect</sup> grown on SWG or SWG medium supplemented with 2.5 mM 3-AT in petri dishes. Insets show a detailed view of perithecia or sterile mycelium. The images were taken seven days post inoculation. (B) Foraging capacity of indicated strains. Agar plugs of 0.5-cm diameter were transferred into empty cell-culture plates (6 well, 17.2 ml) and incubated for 5 d at 27°C in a damp chamber before photographed. (C) The growth velocity of wt,  $\Delta$ Smatg12 and the complemented strain was analyzed by measuring the growth velocity in cm/day in 30-cm race tubes. Growth rates on SWG medium shown are averages from 7 independent measurements of three independent experiments (n= 21), standard deviations are indicated by error bars. Asterisk indicates significant difference to wt according to Student's t-test ( $p < 0.0000001$ ). (D) Microscopic investigation of sexual development of  $\Delta$ Smatg12 compared to wt and the complemented strain. Strains were grown on SWG medium. Expression of the EGFP-SmATG12 fusion construct complemented the sterile phenotype of  $\Delta$ Smatg12. The wt and the complemented strain  $\Delta$ Smatg12::egfp-Smatg12<sup>ect</sup> form ascogonia at day 3, and protoperithecia at day 4 post inoculation. These develop to pigmented protoperithecia at day 5 and to mature perithecia at day 7. Sexual development of the mutant  $\Delta$ Smatg12 is blocked at the stage of protoperithecia formation.  $\Delta$ Smatg12 neither forms pigmented protoperithecia nor perithecia and ascospores. Scale bars as depicted.

Microscopic investigation of the fruiting-body development revealed that the mutant was arrested at the protoperithecia-developmental stage and was unable to form mature fruiting bodies or ascospores (Figure 15A+D). Altogether, five independent homokaryotic deletion mutants and two independent complemented mutants which displayed homogenous phenotypes were analyzed. Thus, the observed phenotypes are associated with the deletion of the *Smatg12* gene.

### **3.1.3 EGFP-SmATG12 localizes to phagophore assembly sites**

To investigate the *in vivo* localization of SmATG12, the complementation strain  $\Delta$ *Smatg12::egfp-Smatg12<sup>ect</sup> was used. The ectopically integrated *egfp-Smatg12* fusion construct, under the control of the endogenous promoter, was able to complement the sterile phenotype of  $\Delta$ *Smatg12* (Figure 15). Fluorescence microscopy of the functionally expressed EGFP-SmATG12 fusion protein in the proliferating mycelium (24 h after inoculation) revealed localization in the cytoplasm as small discrete dots or cup-shaped structures that were presumed to be phagophore assembly sites or growing phagophores (Figure 16A). In the  $\Delta$ *Smatg8* mutant, the EGFP-SmATG12 fluorescence signals appeared larger and more distinct than that of the complemented  $\Delta$ *Smatg12* mutant (Figure 16B). To investigate the role of SmATG12 in autophagy, the autophagy-mediated engulfment of EGFP-labeled SmATG8 into the vacuole was examined. Transformation of pRS-*egfp-Smatg8* (Voigt and Pöggeler 2013a) into  $\Delta$ *Smatg12* allowed us to follow the fluorescence signal of EGFP-labeled autophagosomes. In contrast to the complemented  $\Delta$ *Smatg8* mutant, in the  $\Delta$ *Smatg12* mutant EGFP-SmATG8 fluorescence was diffused throughout the cytoplasm, and large cytoplasmic aggregates were excluded from vacuoles, even in basal hyphae (Figure 16D).*

**Figure 16: Fluorescence microscopic localization of EGFP-SmATG12 and EGFP-SmATG8.**

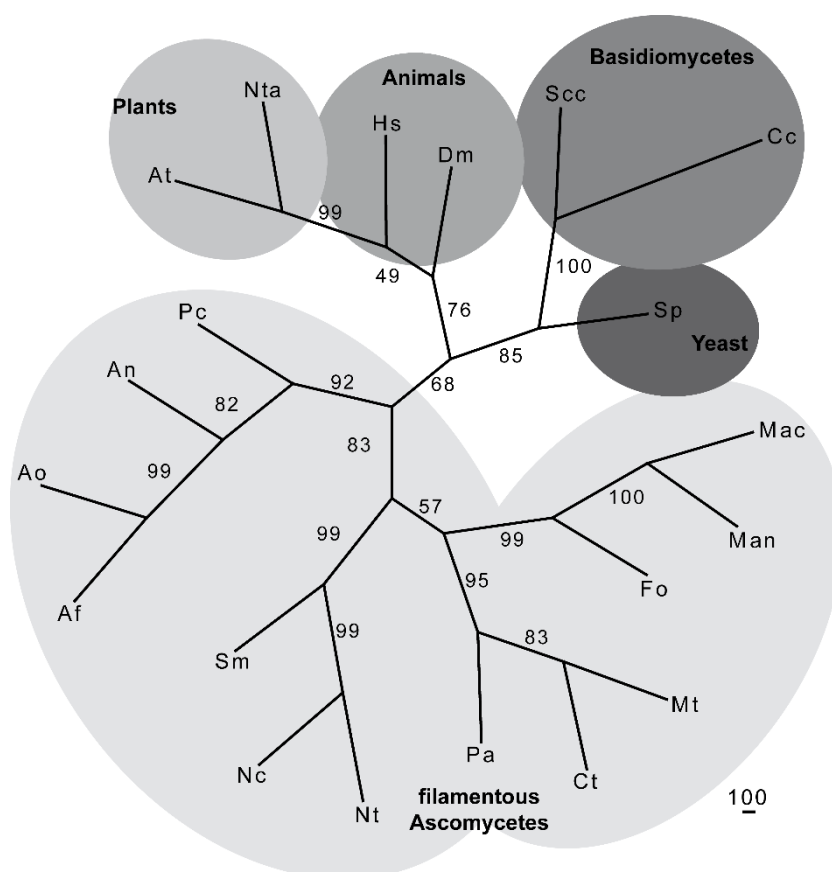

(A) Mutant  $\Delta$ Smatg12 was transformed with plasmid *pegfp-Smatg12*. Expression of the EGFP-SmATG12 fusion construct complemented the sterile phenotype of  $\Delta$ Smatg12. EGFP-SmATG12 localizes to the cytoplasm and at phagophore assembly sites indicated by small arrows and cup-shaped phagophores indicated by long arrows. Vacuolar membranes were stained using FM4-64. The merged picture shows a close up. (B) Localization of EGFP-SmATG12 in the  $\Delta$ Smatg8 mutant (Voigt and Pöggeler 2013a). The fluorescence signals are larger and more distinct than signals in the complemented mutant  $\Delta$ Smatg8::*egfp-Smatg8<sup>ect</sup>* (compare to E). (C) The fluorescence signal of free EGFP in the wt strain transformed with plasmid *p1783-1* served as control. (D) When the mutant strain  $\Delta$ Smatg12 expressed EGFP-SmATG8 (plasmid *pRS-egfp-Smatg8* (Voigt and Pöggeler 2013a)), the fluorescence protein displays an equal diffused signal in the cytoplasm with large accumulating spots (arrow head) which are excluded from the vacuole. Vacuolar membranes were co-stained with FM4-64 and pictures were merged. (E) The previously constructed strain  $\Delta$ Smatg8::*egfp-Smatg8<sup>ect</sup>* (Voigt and Pöggeler 2013a) was used to compare the localization of EGFP-SmATG8 in the  $\Delta$ Smatg12 mutant. Autophagosomes are indicated by arrows. DIC, differential interference contrast; EGFP, enhanced green fluorescence protein. Autophagy was induced by the addition of 2.5 mM 3-AT to the SWG medium or by nitrogen starvation conditions (SWG-N, without  $\text{KNO}_3$  and arginine). Scale bars as depicted.

These microscopic observations correlate with the EGFP-SmATG8 degradation analysis by Western blotting (Figure 14). Vacuolar membranes were stained with the membrane dyes FM4-64. The localization did not change when histidine starvation was induced by 3-AT (Voigt and Pöggeler 2013a) or when strain grew under nitrogen-limiting conditions. Fluorescence microscopy revealed the expected localization of EGFP-SmATG8 in vacuoles and in autophagosome-like structures (distinct spots in the cytoplasm) as well as in basal hyphal compartments in the lumen of the vacuoles in the complemented  $\Delta$ Smatg8 (Figure 16E) (Voigt and Pöggeler 2013a). These results indicated that macroautophagy was disrupted in the  $\Delta$ Smatg12 mutant.

## 3.2 Identification of the selective autophagy cargo receptor SmNBR1

### 3.2.1 The cargo receptor SmNBR1 of *S. macrospora* is conserved in higher eukaryotes and displays a similar domain architecture

In a study, to identify interacting proteins of the ubiquitin-like autophagy protein SmATG8 a GFP-Trap analysis was used followed by LC/MS, and identified among other proteins a protein that had sequence similarity to the mammalian selective autophagy cargo receptor NBR1 (Voigt 2012). The identified protein is encoded by the 2681-bp ORF *SMAC\_07844* and has 863 amino acids (aa) with a predicted molecular weight of 96 kDa. The splicing of a predicted single intron (92 bp) within the ORF was confirmed by sequencing the cDNA. A phylogenetic analysis was performed based on 20 NBR1 homologs of different species including filamentous ascomycetes, basidiomycetes, *H. sapiens*, *A. thaliana* and *S. pompe*. The unrooted neighbor joining tree demonstrates that NBR1 homologs from filamentous ascomycetes form a distinct clade (Figure 17).

**Figure 17: Unrooted phylogenetic neighbor-joining tree of NBR1 homologs from 20 species.**

The phylogenetic relationship based on the alignment of the full-length NBR1 homologs. The number at the nodes indicate the percentage of bootstrap support based on 1000 bootstrap replications. Abbreviations and accession numbers of proteins are as follows: filamentous Ascomycetes: Sm, *Sordaria macrospora* (XP\_003346367); Nc, *Neurospora crassa* (XP\_011394647); Nt, *Neurospora tetrasperma* (XP\_009847604); Pa, *Podospira anserina* (XP\_001912058); Mt, *Myceliophthora thermophila* (MYCTH\_2302632); Ct, *Chaetomium thermophilum*

## Results

(XP\_006696593); Man, *Metarhizium anisopliae* (EFY98453); Mac, *Metarhizium acridum* (EFY92904); Fo, *Fusarium oxysporum* (EMT63555); Af, *Aspergillus fumigatus* (XP\_755022); Ao, *Aspergillus oryzae* (XP\_001824430); An, *Aspergillus nidulans* (XP\_661032); Pc, *Penicillium chrysogenum* (XP\_002563338); Basidiomycetes: Scc, *Schizophyllum commune* (XP\_003038660); Cc, *Coprinopsis cinerea* (XP\_001829200); Plants: At, *Arabidopsis thaliana* (NP\_194200); Nta, *Nicotiana tabacum* (NP\_001312077); Animals: Hs, *Homo sapiens* (Q14596); Dm, *Drosophila melanogaster* (NP\_648826); Yeast: Sp, *Schizosaccharomyces pombe* (Q9P792).

The identified ORF of *S. macrospora* revealed a conserved domain architecture, including an N-terminal PB1 domain followed by CC domains, four ZZ-type zinc-finger domains, a NBR1 box domain and an ATG8-interacting motif (LIR) (Figure 18, Supplement 3). Similar to other fungal NBR1 homologs, the *S. macrospora* protein SmNBR1 lacks the C-terminal UBA domain, which is found in the plant and mammalian homologs.

**Figure 18: Schematic representation of cargo receptor homologs and specific domains.**

(A) Protein architecture of NBR1 homologs of *H. sapiens*, *A. thaliana*, *S. pombe* and *S. macrospora*: PB1, PhoX and Bem1 domain; ZZ, ZZ-type zinc-finger domain; CC, coiled-coil domain; NBR1-domain, LIR, LC3-interacting region; JUBA, juxta-ubiquitin-associated domain; UBA, ubiquitin-associated domain; CR, conserved region. Scale bar is indicated. (B) Alignment of 13 NBR1 homologs of filamentous ascomycetes revealed a fungal specific conserved region at the C-terminus. Sm, *Sordaria macrospora* (XP\_003346367); Nc, *Neurospora crassa*

(XP\_011394647); Nt, *Neurospora tetrasperma* (XP\_009847604); Pa, *Podospora anserina* (XP\_001912058); Mt, *Myceliophthora thermophila* (MYCTH\_2302632); Ct, *Chaetomium thermophilum* (XP\_006696593); Man, *Metarhizium anisopliae* (EFY98453); Mac, *Metarhizium acridum* (EFY92904); Fo, *Fusarium oxysporum* (EMT63555); Af, *Aspergillus fumigatus* (XP\_755022); Ao, *Aspergillus oryzae* (XP\_001824430); An, *Aspergillus nidulans* (XP\_661032); Pc, *Penicillium chrysogenum* (XP\_002563338). Asterisks label the three conserved serine (S) residues. (C) Sequence logo was made using WebLogo 3 of the fungal NBR1 LIR motifs. Species as listed in B. (D) Alignment of the NBR1 box of the following species: Sm, *Sordaria macrospora* (XP\_003346367); Nc, *Neurospora crassa* (XP\_011394647); At, *Arabidopsis thaliana* (NP\_194200); Hs, *Homo sapiens* (Q14596). Asterisks label the four conserved tryptophan (W) residues typical for this domain.

Furthermore, in the alignment of NBR1 homologs a conserved region (CR) was identified near the NBR1 domain, which is characteristic for filamentous ascomycetes and less conserved in basidiomycetes (Figure 18B, Supplement 3A, including basidiomycetes), but not present in mammalian, plant or the fission yeast NBR1 receptors. Within this specific region, three serine (S) residues are conserved (Figure 18B). The amino-acid alignment from the filamentous ascomycetes identified also a sequence corresponding to the LIR consensus sequence (X<sub>3</sub>-X<sub>2</sub>-X<sub>1</sub>-(W/Y/F<sub>0</sub>)-X<sub>1</sub>-X<sub>2</sub>-(L/I/V<sub>3</sub>)-X<sub>4</sub>-X<sub>5</sub>) (Alemu et al. 2012) at the C-terminus of SmNBR1 and fungal NBR1 homologs. All of them have an aromatic (Y) and a hydrophobic (L) residue at position W<sub>0</sub> and L<sub>3</sub>, respectively. Within this region X<sub>1</sub> to X<sub>3</sub> amino acids are acidic residues (E, D) and X<sub>4</sub> is a conserved threonine (T) (Figure 18C, Supplement 3B, including basidiomycetes). The SmNBR1 protein harbors a NBR1 box with four conserved tryptophan residues (Figure 18D). Despite these conserved features, fungal NBR1 homologs lack the UBA-domain. A careful inspection of the protein sequence did not identify a UBA domain.

### 3.2.2 The *Smnbr1* deletion mutant displays developmental defects

To elucidate the function of SmNBR1, a *S. macrospora Smnbr1* deletion mutant was generated by homologous recombination with a *hph*-deletion cassette flanked by upstream and downstream sequences of the *Smnbr1* ORF (2.2.6.1). The deletion of *Smnbr1* was confirmed by PCR and Southern blot analysis (Figure 19). Macroscopic and microscopic investigations of the  $\Delta$ *Smnbr1* strain revealed several developmental defects in comparison to the wild type and to a complemented strain expressing a *Smnbr1-egfp* fusion gene ectopically ( $\Delta$ *Smnbr1::Smnbr1-egfp<sup>ect</sup>*) (Figure 20). *S. macrospora* wild type and the complementation strain completed the life cycle within seven days under laboratory conditions. It starts with a germinating ascospore developing into a haploid vegetative mycelium. After three days, sexual development begins with the formation of female gametangia (ascogonia) which are protected by sterile hyphae that develop into a spherical fruiting-body precursor (protoperithecia). Cell

## Results

differentiation leads to pigmentation after 5 days followed by development of the mature fruiting bodies (perithecium). During perithecia development after karyogamy, meiosis and a postmeiotic mitosis takes place, giving rise to eight linearly-ordered black ascospores per ascus (approximately 200 asci per perithecium). The ascospores are discharged through an apical pore (ostiole) at the neck of the fruiting body (Teichert et al. 2014). Microscopic analysis of the sexual reproductive structures of the  $\Delta$ *Smnbr1* strain showed defects at late stages of fruiting-body development. The mutant formed ascogonia, protoperithecia and perithecia but in a reduced number and after a prolonged time (Figure 20A+B).

**Figure 19: Generation and analysis of a  $\Delta$ *Smnbr1* knockout strain.**

(A) Schematic representation of the *Smnbr1* (*SMAC\_07844*, dark grey arrow) genomic region and its flanking regions including adjacent genes *SMAC\_07843* and *SMAC\_07845* (white arrows). The verified intron is indicated with a white bar. (B) Gene locus after homologous recombination of the *hph*-resistance gene under the control of the *trpC* promoter of *A. nidulans* (*PtpC* and *hph*, grey arrow). The positions of primers to construct and verify homologous recombination at the *Smnbr1* locus are indicated as small black arrows. *PstI* restriction sites are labeled. (C) Southern blot analysis of wt and  $\Delta$ *Smnbr1* strain. Genomic DNA was digested with *PstI* and hybridized with the probe indicated in A and B. Hybridization resulted in a 4828-bp band for the wt and a 3565-bp band for the knockout strain. (D) PCR analysis with primer pairs *Smnbr1*-v5f/*Smnbr1*-vORF5-r (1425 bp) and *Smnbr1*-vORF3-f/*Smnbr1*-v3r (1133 bp) to verify the absence of the *Smnbr1* gene in  $\Delta$ *Smnbr1* and the presence in wt. The presence of the *hph*-resistance cassette at the desired gene locus was verified with primer pairs *Smnbr1*-v5f/tC1 (1166 bp) and h3/*Smnbr1*-v3r (873 bp) (PCR not shown). Additionally, the primer pair *Smnbr1*-ko-5f/*Smnbr1*-ko-3r was used to verify the presence of the *hph* gene (3254 bp) in comparison to wt (4433 bp) (PCR

not shown). Position of the primers are indicated in (A) and (B). (E) PCR analysis of the cDNA (2592 bp) and gDNA (2684 bp) of *Smnbr1* which showed a bandshift induced by the splicing of the 92-bp intron. The primer pair Nbr1ORF-f/GFPNbr1r was used indicated in (A).

The ascus rosettes of the mutant harbored incomplete asci with few mature, melanized ascospores (Figure 20A,C,D). In the complemented strain these defects are partially rescued. Quantitative analysis of fruiting bodies showed a 97.5 % reduction of mature perithecia per cm<sup>2</sup> in the knockout strain in comparison to the wild type (Figure 20B). Consequently, the number of discharged mature ascospores, which are essential for reproduction, was also drastically reduced (99 % reduction in comparison to wild type) (Figure 20C).

## Results

**Figure 20: Phenotypic analysis of *S. macrospora* wt,  $\Delta$ Smnbr1 mutant strain and complementation strains expressing *S. macrospora* or *H. sapiens* NBR1 proteins.**

(A) Microscopic investigation of sexual development of  $\Delta$ Smnbr1 compared to wt and the complemented strains  $\Delta$ Smnbr1::Smnbr1-egfp<sup>ect</sup> and  $\Delta$ Smnbr1::Hsnbr1-Dsred<sup>ect</sup>. Strains were grown on slides covered with fructification medium (SWG), and photographs were taken at indicated days. (B) The perithecia were counted per cm<sup>2</sup> after eight days (wt,  $\Delta$ Smnbr1::Smnbr1-egfp<sup>ect</sup>) or ten days ( $\Delta$ Smnbr1). Number of perithecia shown are averages from nine independent measurements of three independent experiments (n=27). (C) Discharged ascospores, after ten days of growth, from the lid of a petri dish (56.7 cm<sup>2</sup>) for the different strains. (D) Ascus rosettes were analyzed at the same time point as in (B). Microscopic pictures represent a part of representative ascus rosettes. All strains were grown on fructification medium (SWG). Wt was set to 1. Results of (C) and (D) are averages from 25 independent measurements of four independent experiments (n=100). Standard deviations are indicated by error bars (B) and (C) and scale bars are shown in the images. (\*) Asterisks indicate significant differences in the deletion mutant in comparison to the wt according to Student's t-test (p<0.0000001).

Microscopic analysis showed that the mature perithecia of the knockout strain contained a high number of undeveloped asci and unviable ascospores in comparison to the wild type (Figure 20D). Thus, we showed that the deletion of *Smnbr1* decreased the production of mature perithecia, with an increased number of defective asci and ascospores.

The SmNBR1 homolog shares only 22 % identity to the NBR1 protein from *H. sapiens*. However, many domains of the *H. sapiens* NBR1 protein (HsNBR1) are conserved in SmNBR1. Therefore, we analyzed whether the HsNBR1 protein can complement the  $\Delta$ Smnbr1 phenotype by expressing the protein in the  $\Delta$ Smnbr1 strain. For this,  $\Delta$ Smnbr1 was transformed with the plasmid pHsnbr1-Dsred. Subsequently, 20  $\Delta$ Smnbr1::Hsnbr1-Dsred<sup>ect</sup> transformants were phenotypically analyzed. After ten days growth on SWG medium 14 of 20 transformants show complementation by producing mature perithecia and ascospores as the *S. macrospora* complementation strain. The six other transformants were not able to rescue the phenotypical defects of  $\Delta$ Smnbr1 perhaps due to the ectopic integration of the heterologous gene (data not shown). Three of the 14 complementation strains expressing the HsNBR1 protein were tested phenotypically in more detail. Strains were able to form ascogonia, protoperithecia and perithecia. The maturation of the late developmental stages are more delayed in comparison to the wild type because the pigmented protoperithecia and perithecia looked smaller. In contrast to the mutant  $\Delta$ Smnbr1, the *H. sapiens* complementation strain shows more mature ascospores in ascus rosettes after ten days of growth. In summary, the developmental defects of the mutant  $\Delta$ Smnbr1 can be partially rescued by the human NBR1 homolog (Figure 20A). The heterologous production of HsNBR1-DsRED was verified by a Western-blot experiment (Supplement 4).

Due to the fact that SmNBR1 lacks an obvious UBA domain we tested the enrichment of ubiquitinated proteins in total protein extracts of wild type,  $\Delta$ Smnbr1 (two independent mutants) and a control strain  $\Delta$ Smubp3 (Herzog pers. comm.). The deubiquitination enzyme SmUBP3 is able to bind ubiquitinated proteins to remove the ubiquitin tag for their autophagosomal degradation (Kraft et al. 2008). The Western-blot analysis showed that the  $\Delta$ Smnbr1 strains behave like the wild type strain whereas the  $\Delta$ Smubp3 strain showed a high accumulation of ubiquitinated proteins, however several bands seem to be more intensive in the  $\Delta$ Smnbr1 strain as in the wild type (Figure 21).

**Figure 21: Western blot using anti-ubiquitin to detect ubiquitinated proteins.**

Western blot using equal amounts of protein extracts of wt,  $\Delta$ Smnbr1 and  $\Delta$ Smubp3 (control) strain. Ubiquitinated proteins were detected with an ubiquitin antibody. Detection of actin was used as loading control to show the protein levels. One of three Western-blot experiments is represented. Quantification of Western blots was done using the program ImageJ. For this the ubiquitin protein amount was quantified to the actin loading control. Wt was set to 100 %. Data in this diagram are represented for three independent experiments. Error bars are indicated.

### 3.2.3 Stress conditions enhance developmental defects of $\Delta$ Smnbr1

Autophagy enables cells to adapt to new conditions or to overcome starvation or environmental stress conditions. Therefore, we tested whether deletion of *Smnbr1* leads to growth and adaptation defects under different stress conditions. For this the growth rate was measured using race tubes (2.2.1). The vegetative growth rate of the deletion strain was only slightly reduced to 2.6 cm/d compared to 3.1 cm/d of the wild type strain under normal growth conditions (SWG medium). In contrast, under histidine-starvation conditions induced by the drug 3-amino-1,2,4-triazole (3-AT) or nitrogen starvation by omitting  $\text{KNO}_3$ /arginine in the SWG medium the  $\Delta$ Smnbr1 mutant showed a significant reduction of the growth rate in comparison to the wild type (Figure 22A). To test the sensitivity of the  $\Delta$ Smnbr1 strain to other stress conditions we induced different kinds of stresses, such as amino-acid starvation, osmotic-, oxidative-, or cell wall stress conditions by adding to the SWG medium 2.5 mM 3-AT, 0.5 M sorbitol, 0.25 mM NaCl, 0.02 %  $\text{H}_2\text{O}_2$  or 0.005 % SDS, respectively. Additionally, nitrogen starvation was performed by limiting the nitrogen sources  $\text{KNO}_3$ , arginine or biotin and temperature stress was induced by cultivating the strains at 20°C or 32°C (Figure 22B).

While the wild type and the complemented strain displayed normal vegetative growth under all conditions tested, the  $\Delta$ Smnbr1 knockout strain showed defects under different stress conditions. Mostly, the mutant was unable to cover the whole petri dish and often it terminates the growth, such as observed under osmotic stress (sorbitol, NaCl), starvation conditions (3-AT) and temperature stress. Nitrogen starvation and oxidative stress inhibited fruiting-body development of the knockout strain characterized by production of little or no protoperithecia or perithecia.

The fact that developmental defects of the  $\Delta$ Smnbr1 can be almost completely rescued by complementation of the deletion strain with the wild type *Smnbr1* gene ( $\Delta$ Smnbr1::*Smnbr1*-egfp<sup>ect</sup>), verifies that the developmental phenotype results from the lack of the SmNBR1 function (Figure 22). Taken together, phenotypical characterization under stress conditions revealed that SmNBR1 is necessary for proper fruiting-body development and vegetative growth and required to overcome nutrient limiting and stress conditions.

### 3.2.4 SmATG8 interacts directly with SmNBR1

In mammals and plants it is known that NBR1 and ATG8 interact with each other in a LIR-dependent manner (Johansen and Lamark 2011). Co-immunoprecipitation (Co-IP) experiments with *S. macrospora* wild type strain expressing a DsRED-tagged version of SmNBR1 together with an EGFP-tagged version of SmATG8 confirmed the interaction between both proteins *in vivo* (Figure 23A).

To validate the interaction of SmATG8 and SmNBR1, and to specify the interacting domains, we performed a yeast-two hybrid (Y2H) analysis with the full-length protein and different truncated or mutated versions of SmNBR1. For this purpose, *Smnbr1* and *Smatg8* cDNAs were cloned into the two-hybrid vectors pGBKT7 (bait) and pGADT7 (prey), respectively, either harbouring the Gal4-binding or Gal4-activation domain. We observed that the full-length protein SmNBR1 can interact with SmATG8 when SmNBR1 is fused to the Gal4-activation domain and SmATG8 is fused to the Gal4-binding domain. No interaction was observed when SmNBR1 was fused to the binding domain and SmATG8 to the activation domain while the positive control pAD-ranBPM in combination with pBD-Smnbr1 was functional. All controls for self-activation were tested negatively (data not shown). Therefore, we coupled all the different versions of SmNBR1 to the Gal4-activation domain (Figure 23B,C).

**Figure 23: Interaction studies with SmNBR1 and SmATG8.**

(A) Co-IP of SmNBR1 and SmATG8 and subsequent Western-blot analysis with anti-EGFP and anti-RFP antibodies from indicated strains. Expression of an EGFP-SmATG8 and SmNBR1-DsRED fusion construct in the wt strain. The respective complementation strains ( $\Delta$ Smatg8::egfp-Smatg8<sup>ect</sup>,  $\Delta$ Smnbr1::Smnbr1-Dsred<sup>ect</sup>) and wt strains were used as controls. (B) Schematic display of the domain architecture of different yeast-two hybrid *Smnbr1* constructs. (C) Yeast-two hybrid analysis: yeast strains expressing the fusion constructs AD-SmATG8 (activation domain of the Gal4-transcription factor encoded by pGADT7) and BD-SmNBR1 (binding domain of the Gal4-transcription factor encoded by pGBKT7) are not able to interact in contrast to the fusion of AD-SmNBR1 and BD-SmATG8. All mutated versions of AD-SmNBR1 and the C-terminal region (419-863) show a reduced interaction with BD-SmATG8. The other C-terminally truncated versions of SmNBR1 (1-418; 1-843) fused to the activation domain, do not interact with BD-SmATG8. The mated yeast cells were grown on SD minimal medium-*trp* and -*leu* (SD-TL) for selection of the plasmids. SD media lacking -*trp*, -*leu*, -*his*/-*ade* (SD-TLH/A) were used for interaction studies. Each drop assay was performed in 10-fold serial dilutions ( $10^{-1}$ - $10^{-4}$ ). Here, the growth of the first dilution is shown. As a negative control, the query vectors pGADT7/pGBKT7, and for positive control the pAD-ranBpm/pBD-Smnbr1 and pBD-Smatg8 were used. RanBpm can be used as positive control because it is able to interact with the Gal4-BD (Tucker et al. 2009). To quantify the interaction of SmNBR1 and SmATG8 with the *lacZ*-reporter gene, the X-Gal activity was measured based on a PXG assay. The results are also represented in a bar diagram based on averages from 3-6 independent experiments of four identical measurements. The black line depicts the threshold based on the negative control. Error bars are indicated in the diagram.

The full-length protein SmNBR1 is able to interact with SmATG8 confirming the results of the Co-IP analysis. To define the interaction domain of both proteins more closely, truncated versions of SmNBR1 were constructed consisting of either the N-terminal part (aa 1-418), the C-terminal part (aa 419-863) or a truncated version without the LIR motif (SmNBR1 1-843) and tested for interaction with SmATG8. Interestingly, only the C-terminal part of SmNBR1 containing the LIR and the CR motif was able to interact with SmATG8 (Figure 23B,C).

Additionally, mutated SmNBR1 variants were analyzed in which Tyr 843, Thr 847 and/or Leu 850 residues in the conserved TxxxYxxL LIR motif and Ser 793, 804, 808 in the CR motif were exchanged by Ala. When the LIR motif was deleted or mutated ( $\Delta$ aa 842-863 of SmNBR1; Y<sup>847</sup>A L<sup>850</sup>A; T<sup>843</sup>A; T<sup>843</sup>A Y<sup>847</sup>A L<sup>850</sup>A) interaction was abolished or impaired, as was the case for truncated versions without LIR motif. This indicates that the LIR motif is required for interaction with SmATG8. We tested also the impact of the CR motif for interaction with SmATG8. Mutation of the S<sup>793</sup>A S<sup>804</sup>A S<sup>808</sup>A revealed also a reduced interaction ability.

### 3.2.5 SmNBR1 localizes in autophagosome-like structures and vacuoles

To determine the cellular localization of SmNBR1, we performed fluorescence microscopy using functionally expressed SmNBR1-DsRED or SmNBR1-EGFP. For this purpose, we used the complementation strains  $\Delta$ Smnbr1::Smnbr1-Dsred<sup>ect</sup> and  $\Delta$ Smnbr1::Smnbr1-egfp<sup>ect</sup> harboring the plasmids pSmnbr1-Dsred or pSmnbr1-egfp encoding either C-terminally tagged *Smnbr1-Dsred* or *Smnbr1-egfp* fusion genes under the control of the native promoter (SmNBR1-EGFP is shown in Supplement 5). As a localization control, fluorescence microscopy was performed with wild type transformants expressing only DsRED from plasmid pRHN1, and EGFP from plasmid p1783-1. When DsRED or EGFP were expressed individually, both proteins were found to be located in the cytoplasm in an even distribution (Figure 24B). SmNBR1 tagged with either EGFP or DsRED is localized as distinct spots in the cytoplasm, presumably representing autophagosomes, and is transported to the vacuole, indicating vacuolar degradation of the tagged protein. Additionally, the wild type strain was co-transformed with plasmids pSmnbr1-Dsred and pRS-egfp-Smatg8 which encodes EGFP fused N-terminally to SmATG8 under the control of its native promoter. The merged images show co-localization of EGFP-SmATG8 and SmNBR1-DsRED in cytosolic autophagosome-like structure and in vacuoles of young and old hyphae (Figure 24A).

**Figure 24: Localization of the autophagy proteins SmNBR1 and SmATG8.**

(A) Fluorescence microscopic analysis of an *S. macrospora* wt strain carrying the plasmids pSmnbr1-Dsred and pRS-egfp-Smatg8 expressing a SmNBR1-DsRED and EGFP-SmATG8 fusion construct, respectively. At the hyphal tips EGFP-SmATG8 fluorescence is distributed in punctuated autophagosome-like structures and larger aggregates in direct contact with SmNBR1-DsRED. In older basal hyphae, both proteins are concentrated in the vacuoles. Co-localization of SmNBR1 and SmATG8 is shown in yellow in the merged pictures. Arrows point to autophagosomes. (B) Fluorescence microscopy of wt strains encoding EGFP or DsRED (wt::1783-1<sup>ect</sup>; wt::RHN1<sup>ect</sup>) to analyze the fluorescence signal of free EGFP and DsRED. Both signals are distributed in the cytoplasm. (C) BiFC experiment using a wt strain harboring the plasmids pSmnbr1-YC and pYN-Smatg8. The interaction of SmNBR1-YC and YN-SmATG8 is indicated by a yellow fluorescence signal (YFP). Arrows point to autophagosomes. (D) Fluorescence control strains for the BiFC assay. Wt transformed with vectors pSmnbr1-YC and pYN-Smatg8 in single or co-transformed with the empty vectors pRS-YC and pRS-YN. All controls cannot emit the excitation light coming from YN or YC. DIC, differential interference contrast. Scale bars are indicated.

In order to verify the interaction of SmNBR1 and SmATG8 by another independent method, we performed a bimolecular fluorescence complementation (BiFC) assay, which is based on the split yellow fluorescent protein (YFP) (Hu and Kerppola 2003). YFP is divided in an N-terminal and a C-terminal part and both non-fluorescent fragments (YN and YC) were fused to putative interacting proteins SmATG8 and SmNBR1, respectively. Plasmids were transformed in the *S. macrospora* wild type strain. The association of the interaction partners allows the formation of a bimolecular fluorescent complex, which results in a YFP signal. The yellow fluorescence signal appeared in vacuoles and also in autophagosome-like structure (Figure 24C, arrows), further confirming the interaction of both proteins and their localization to vacuoles

and autophagosomes. As control, fluorescence microscopy was also performed with wild type transformants expressing only SmNBR1-YC or YN-SmATG8, or in combination with the respective empty vector to exclude self-activation (Figure 24D).

SmATG8 is a main component for the formation of the autophagosomes (Voigt and Pöggeler 2013a). Beside SmATG8, the ubiquitin-like autophagy protein SmATG12 was also analyzed to be essential for autophagy in *S. macrospora* (see 3.1) (Werner et al. 2016). To determine the dependency of SmNBR1 and the core autophagy proteins SmATG12 and SmATG8 during autophagy we observed distribution of fluorescent SmATG8 and SmNBR1 in these deletion mutants. Interestingly, in contrast to the pattern observed in the control strain (complementation strain), the fluorescence signal of the SmNBR1-DsRED fusion protein was detected as aggregates in the cytoplasm but was absent from the vacuoles in the autophagy mutants  $\Delta$ Smatg8 and  $\Delta$ Smatg12. Furthermore, the dot-like structures were larger and fewer in number than those observed in the control strain. Thus, SmNBR1 was not translocated to the vacuoles, neither in the  $\Delta$ Smatg8 nor in the  $\Delta$ Smatg12 knockout mutant, indicating the dependency of the vacuolar localization of SmNBR1 on the core autophagy machinery (Figure 25A). We also analyzed the localization of EGFP-SmATG8 in a  $\Delta$ Smnbr1 knockout strain to determine whether the localization of SmATG8 to the vacuole is in turn dependent on SmNBR1 (Figure 25B). However, the EGFP-SmATG8 fusion protein localized to vacuoles and autophagosomes in  $\Delta$ Smnbr1, similar to the the complemented strain  $\Delta$ Smatg8::egfp-Smatg8<sup>ect</sup> (Figure 25B).

**Figure 25: Fluorescence microscopic analysis of *S. macrospora* SmNBR1 and SmATG8 in different deletion mutants.**

(A) The deletion strains  $\Delta$ Smnbr1,  $\Delta$ Smatg12,  $\Delta$ Smatg8 were transformed with pSmnbr1-Dsred, expressing a SmNBR1-DsRED fusion construct. SmNBR1 is localized in the cytoplasm as large aggregates and is excluded from the vacuoles in  $\Delta$ Smatg12 and  $\Delta$ Smatg8. Arrows point to autophagosomes. (B) Analysis of EGFP-SmATG8 localization in the  $\Delta$ Smnbr1 and  $\Delta$ Smatg12 knockout strains and the control strain  $\Delta$ Smatg8 each carrying the plasmid pRS-egfp-Smatg8. EGFP-SmATG8 localized in  $\Delta$ Smnbr1 and  $\Delta$ Smatg8 strains to vacuoles and autophagosomes which are indicated by arrows. Vacuoles were stained with CMAC. DIC, differential interference contrast. Scale bars are indicated.

This could be also verified by the quantitative determination of the ratio between the intact autophagy marker protein EGFP-SmATG8 and free EGFP. The EGFP-SmATG8 protein is rapidly degraded in the vacuole whereas the cleaved EGFP moiety is stable in the vacuole (Klionsky et al. 2016). EGFP-SmATG8 is not or slightly degraded in  $\Delta$ Smatg4 and in  $\Delta$ Smatg12 autophagy mutants. In contrast, vacuolar cleavage of EGFP could be detected in the complementation strain  $\Delta$ Smatg8::egfp-Smatg8<sup>ect</sup> as well as in the  $\Delta$ Smnbr1::egfp-Smatg8<sup>ect</sup> strain (Figure 26A). This effect was enhanced by cultivating the strains under autophagy-inducing conditions (Supplement 6, BMM+2.5 mM 3-AT). Expression analysis of SmNBR1-DsRED in a  $\Delta$ Smatg8 or  $\Delta$ Smatg12 strain revealed that the SmNBR1-DsRED fusion protein is not degraded (Figure 26B). Hence, vacuolar targeting of SmNBR1 depends on autophagy, but the general autophagy process is not affected in the absence of SmNBR1.

**Figure 26: Quantitative Western experiments of the vacuolar degradation of EGFP-SmATG8 or SmNBR1-DsRED in different autophagy mutants.**

(A) Expression of an EGFP-SmATG8 fusion construct in different autophagy mutants was determined by Western blotting using a monoclonal anti-EGFP antibody. Wt and a strain expressing free EGFP served as controls. The strains were grown for 3 d in complex media (BMM). The crude protein extracts analyzed were prepared from strains  $\Delta$ Smatg8::egfp-Smatg8<sup>ect</sup>,  $\Delta$ Smatg12::egfp-Smatg8<sup>ect</sup>,  $\Delta$ Smatg4::egfp-Smatg8<sup>ect</sup>,  $\Delta$ Smnbr1::egfp-Smatg8<sup>ect</sup>, wt::1783-1<sup>ect</sup> and the untransformed wt strain. Ponceau staining served as loading control to check the protein levels. The program ImageJ was used to quantify the ratio between cleaved EGFP and the EGFP-SmATG8 fusion protein. The cleavage of EGFP in the complemented strain  $\Delta$ Smatg8::egfp-Smatg8<sup>ect</sup> was set to 100 %. One of three independent experiments is shown. (B) Anti-RFP Western blot of  $\Delta$ Smnbr1,  $\Delta$ Smatg12 and  $\Delta$ Smatg8 transformed with plasmid pSmnbr1-Dsred. Wt strain and a wt strain expressing a gene coding for the DsRED-tag without any fused protein served as controls. SmNBR1-DsRED shows several bands around 100 kDa. The membrane was stained with ponceau red to show the total protein amount. The blot was quantitative analyzed as described in (A). One Western blot is representatively shown. The diagram shows a quantification of the Western blots of the cleaved DsRED and the SmNBR1-DsRED fusion protein. It is an average of three independent experiments. Error bars are indicated.

### 3.2.6 SmNBR1 displays many putative phosphorylation sites

Since Western blots of SmNBR1 are often associated with many background signals a phosphorylation-site prediction was performed using the software NetPhos3.1 ([www.cbs.dtu.dk/services/NetPhos/](http://www.cbs.dtu.dk/services/NetPhos/)). The program predicted 113 potential phosphorylation sites comprising 56 serine, 45 threonine and 12 tyrosine residues. Two of the predicted phosphorylation sites are T<sup>843</sup> and Y<sup>847</sup> of the LIR motif were forecasted to be potential substrates of the common kinases CK2 and the sarcoma (SRC) kinase, respectively. Additionally, the residues S<sup>793/804/808</sup> could be also identified and were potential substrates of the DNA-dependent protein kinase (DNAPK, phosphatidylinositol-3-kinase related kinase) and glycogen synthase kinase 3 (GSK3). To test for phosphorylation of SmNBR1 *in vivo* we treated total protein extracts of  $\Delta$ Smnbr1::Smnbr1-Dsred<sup>ect</sup> with phosphatase inhibitor or with lambda phosphatase. The treatment of the protein extracts with phosphatase inhibitor and lambda phosphatase revealed more and less signals as without enzymes, respectively (Figure 27). This strongly suggests that SmNBR1 is indeed a substrate for kinases.

**Figure 27: SmNBR1-protein phosphorylation assay.**

(A) Western blot showing the treatment of protein extracts of strain  $\Delta$ Smnbr1::Smnbr1-Dsred<sup>ect</sup> without enzymes (untreated), with phosphatase inhibitor (P-inhibitor) or lambda phosphatase ( $\lambda$ -phosphatase). SmNBR1-DsRED was detected by using anti-RFP. Detection of actin is used to show the protein levels loaded. One of three Western-blot experiments is represented. Protein extract of a wt strain expressing free DsRED was used as control. (B) Quantification of Western blots using the program ImageJ. Data in this diagram are represented for three independent experiments. Error bars are indicated.

### 3.2.7 Overexpression of SmNBR1 has no phenotypical effects, but modifications of SmNBR1 prevent complementation of $\Delta$ Smnbr1 and lead to mislocalization

For analyzing how SmNBR1 overproduction affects the growth of *S. macrospora*, a *ccg1-Smnbr1-egfp* overexpression construct was transformed in  $\Delta$ Smnbr1. The resulting strain  $\Delta$ Smnbr1::ccg1-Smnbr1-egfp<sup>ect</sup> behaved like the *Smnbr1-egfp* complementation strain (compare to Figure 22) and no apparent differences were observed under stress-inducing conditions (Figure 28A) as well as in fluorescence microscopic localization studies (Figure 28B).

The two-hybrid studies suggested that the LIR and the CR motif of SmNBR1 are required for interaction of SmNBR1 with SmATG8. To determine which domains of SmNBR1 are functionally important *in vivo*, we performed genetic complementation analysis of  $\Delta$ Smnbr1 with different *Smnbr1* variants the same as used for yeast-two hybrid study (3.2.4). All modified *Smnbr1* versions were tagged with an *egfp* and expressed under the control of the native promoter and therefore could be localized *in vivo* by fluorescence microscopy (Figure 28B).

Interestingly, all truncated SmNBR1 variants were unable to fully complement the  $\Delta$ Smnbr1 phenotype, characterized by less or no production of fruiting bodies and ascospores under normal growth conditions (SWG 27°C, 8 d) as well as under stress-inducing conditions (3-AT, 20°C). Also the vegetative growth is inhibited under stress because the strains were unable to cover the plates with mycelium within 8 d (Figure 28A). These findings correlate with the data of the fluorescence microscopy. Truncated SmNBR1 versions were absent from the vacuole and accumulated in the cytoplasm (Figure 28B).

The double- and single-point LIR motif mutants (*Smnbr1*-Y<sup>847</sup>A L<sup>850</sup>A, *Smnbr1*-T<sup>843</sup>A) were able to form perithecia and discharge mature ascospores in a reduced number under all conditions. In contrast, the triple-point LIR motif mutant (*Smnbr1*-T<sup>843</sup>A Y<sup>847</sup>A L<sup>850</sup>A) displayed a drastically reduced vegetative growth, number of fruiting bodies and mature ascospores. All LIR-motif mutant proteins were located in the vacuole but they show no or less autophagosomes in the cytoplasm.

Transgenic  $\Delta$ Smnbr1 expressing the CR-motif mutant gene *Smnbr1* S<sup>793</sup>A S<sup>804</sup>A S<sup>808</sup>A produced perithecia and ascospores and showed less defects under stress-inducing conditions than LIR-motif mutants. In this strain no apparent differences were observed in the fluorescent localization study in comparison to the complemented strain (Figure 28).

**Figure 28: Phenotypal analysis and fluorescence localization studies of *S. macrospora* ΔSmnbr1 strain transformed with *Smnbr1* variants under normal, low temperature and autophagy-inducing conditions.** (A) All strains were analyzed under the same conditions as indicated above the panels and compared to the wt control and the ΔSmnbr1 knockout strain. Images of agar plates as well as the microscopic images were taken after 8 d of inoculation and after 10 d the lid of petri dishes with the discharged ascospores were documented. The SmNBR1 protein variants contain an EGFP tag. The analysis was done with three biological replicates in three repetitions. (B) Fluorescence microscopic analysis of *S. macrospora* ΔSmnbr1 strains carrying plasmids expressing SmNBR1-EGFP variant fusion constructs. All proteins were detected under the same conditions, cultivated for 24 h on cellophane on complex media. Scale bars are indicated. Arrows indicate autophagosomes.

### 3.3 SmNBR1-dependent pexophagy in *S. macrospora*

In mammals, NBR1 is necessary and sufficient for the turnover of endogenous peroxisomes and acts synergistically with p62 in the pexophagy process (Deosaran et al. 2013; Katarzyna and Suresh 2016). In plants, the NBR1 homolog is involved in aggrephagy and it was speculated that NBR1 may also play a role in pexophagy during heat stress because an over-accumulation of catalases in aggregates of an *Atnbr1* mutant could be observed (Zhou et al. 2014b; Young and Bartel 2016). However, so far the involvement of plant NBR1 in pexophagy was not experimentally verified.

#### 3.3.1 $\Delta$ Smnbr1 fails to grow on fatty-acid and H<sub>2</sub>O<sub>2</sub>-containing medium

In yeasts and filamentous fungi it is known that all steps of  $\beta$ -oxidation are carried out in peroxisomes, leading to the breakdown of long-chain fatty acids to acetyl-CoA, which is then utilized via the glyoxylate cycle (Hiltunen et al. 2003; Hynes et al. 2008). Peroxisomes contain also various antioxidant enzymes and therefore have an active role in regulating ROS in the cell (Wanders and Waterham 2006).

Using a peroxisomal marker protein we tested selective autophagy in *S. macrospora* regarding SmNBR1. For this, the wild type,  $\Delta$ Smnbr1 and the corresponding complementation strain  $\Delta$ Smnbr1::Smnbr1-egfp<sup>ect</sup> were grown on SWG medium and the strains were able to utilize glucose as a carbon source. Under this growth condition  $\Delta$ Smnbr1 is able to form fruiting bodies and ascospores but in a delayed time and in a drastically reduced number (Figure 29A, Figure 20). In order to analyze the role of SmNBR1 in pexophagy we tested the growth of the  $\Delta$ Smnbr1 mutant on medium containing long-chain fatty acids as carbon source or by inducing oxidative stress by adding H<sub>2</sub>O<sub>2</sub> to the growth medium. Wild type,  $\Delta$ Smnbr1 and complementation strain were inoculated on SWG medium with reduced (-75 %) or without glucose together with 0.15 % oleic acid (C18) as carbon source (Figure 29B) or on SWG medium containing 0.01 % or 0.05 % H<sub>2</sub>O<sub>2</sub> (Figure 29C). Under these conditions the growth rate of the  $\Delta$ Smnbr1 strain was drastically reduced compared to the wild type and the complemented strain. In addition, no perithecia and consequently no ascospores were formed in the  $\Delta$ Smnbr1 strain (Figure 29). These results show that fatty-acid metabolism and oxidative-stress resistance is impaired in the  $\Delta$ Smnbr1 strain. Therefore, we tested whether pexophagy is disturbed in  $\Delta$ Smnbr1.

**Figure 29: Growth analysis of wt,  $\Delta$ Smnbr1 and complementation strain under peroxisome-proliferation or oxidative-stress conditions.**

Phenotypic analysis of wt,  $\Delta$ Smnbr1 and  $\Delta$ Smnbr1::Smnbr1-egfp<sup>ect</sup> grown on SWG medium, oleate medium or under oxidative-stress conditions. Images were taken 8 d after inoculation. Lids of petri dishes with discharged ascospores were captured after 10 d. Insets show a magnification of the petri dish. Scale bars are indicated. (A) SWG fructification medium contains glucose as sole carbon source. (B) SWG 0.5 % G+OA or without glucose (SWG-G+OA) was supplemented with 0.15 % oleic acid as carbon source. (C) SWG medium was supplemented with 0.01 % or 0.05 % H<sub>2</sub>O<sub>2</sub>. (D) For the same strains, the growth velocity was analyzed using SWG medium (dark grey bars), SWG 0.5 % G+OA (light grey bars) or SWG supplemented with 0.01 % H<sub>2</sub>O<sub>2</sub> (grey bars). Strains were grown in race tubes for 7 days. Data are means with standard deviations for three biological replicates and three independent experiments. Asterisks show significance analyzed in comparison to wt by students t-test ( $p < 0.0000001$ ).

### 3.3.2 Autophagic degradation of the peroxisomal reporter protein DsRED-SKL arrests in $\Delta$ Smnbr1

In fungi, peroxisomes are degraded in an autophagy-dependent manner as shown for *A. oryzae*, *P. chrysogenum* and *S. macrospora* (Shoji et al. 2010; Bartoszewska et al. 2011; Voigt and Pöggeler 2013a). Proteins containing a PTS1 or PTS2 sequence can be imported into peroxisomes. The PTS1 sequence is characterized by the amino-acid residues SKL. In *S. macrospora* wild type, the peroxisomal marker protein DsRED-SKL is localized to punctate

dots in the cytoplasm and in the vacuole (Elleuche and Pöggeler 2008). However, the vacuolar localization was lost in  $\Delta$ Smatg8 and  $\Delta$ Smatg4 strains, consistent with the predicted roles of these genes in non-selective pexophagy (Voigt and Pöggeler 2013a). In order to analyze the function of SmNBR1 in pexophagy, localization of peroxisomes was investigated by the use of the DsRED-tagged SKL in wild type and the  $\Delta$ Smnbr1 strain. First, we enriched the number of peroxisomes by inoculating the strains on SWG-G+OA medium containing 0.15 % oleic acid (OA) as carbon source. After shifting the strains back to normal growth conditions (SWG) the surplus peroxisomes were degraded in the vacuoles (Figure 30A). The degradation of DsRED-SKL in the wild type strain occurs in the vacuoles, which were co-stained with vacuolar dye CMAC blue.

**Figure 30: Localization studies of the peroxisomal reporter protein DsRED-SKL in wt and  $\Delta$ Smnbr1.**

(A) Fluorescence microscopic investigations of wt strain expressing DsRED-SKL and SmNBR1-EGFP for co-localization of both proteins. (B)  $\Delta$ Smnbr1 strain expressing the DsRED-SKL fusion protein for visualization of peroxisomes. Strains were grown for 24 h on SWG, shifted from SWG to SWG-G+OA medium or after shifting back from SWG-G+OA to SWG. The vacuoles were visualized by co-staining the hyphae with the vacuolar dye CMAC. The corresponding DIC and merged images are shown. Scale bars are indicated. DIC, Differential interference contrast.

DsRED-SKL also co-localizes together with SmNBR1-EGFP in the wild type strain. Both proteins were targeted to the vacuoles for their degradation. In  $\Delta$ Smnbr1 DsRED-SKL was only observed in dot-like structures in the cytoplasm but was always absent from vacuoles after shifting the strain from oleate medium to glucose containing medium (Figure 30B).

In conclusion,  $\Delta$ Smnbr1 showed proliferation of peroxisomes on oleic acid medium and the mutant was not able to degrade excess peroxisomes in the vacuole, indicating that pexophagy is impaired in  $\Delta$ Smnbr1.

### 3.3.3 Peroxisomes change in size, number and morphology in $\Delta$ Smnbr1 and $\Delta$ Smatg8 mutants

In order to confirm the pexophagy defect of  $\Delta$ Smnbr1 we analyzed the degradation of the peroxisomal membrane protein SmPEX14.

PEX14 is a peroxisomal membrane protein and an essential component of the peroxisomal import machinery (Kiel et al. 2006). PEX14 of the filamentous fungus *N. crassa* interacted with both targeting signal receptors and was shown to be localized to glyoxysomes (Managadze et al. 2007; Opalinski et al. 2010). To study distribution and morphology of peroxisomes in the  $\Delta$ Smnbr1 and a further autophagy mutant, plasmid pSmpex14-egfp expressing SmPEX14-EGFP was transformed in wild type,  $\Delta$ Smnbr1 and  $\Delta$ Smatg8 strains. When a wild type strain expressing SmPEX14-EGFP was grown on glucose and transferred to media containing fatty acids instead of glucose (SWG-G+OA) as sole carbon source, an increased number of peroxisomes was visible after 24h and the peroxisomes were degraded in the vacuole after back shifting the strain to normal glucose conditions (Figure 31A). After 24 h the increased number of peroxisomes was reduced to the nearly optimal level. In contrast, peroxisomes show a different morphology, size and number in  $\Delta$ Smnbr1 and the autophagy defective strain  $\Delta$ Smatg8. The fluorescence intensity of SmPEX14-EGFP was increased in both strains at all conditions. Additionally, the signals were more punctured and more evenly distributed in the cytoplasm of the mutants than in wild type (Figure 31A). To quantify these observations, the fluorescence signals of SmPEX14-EGFP were analyzed using ImageJ. For this, the fluorescence signals were counted for each strain under different conditions (Figure 31B). The ImageJ quantification correlates with representative fluorescence images. In wild type, an increase of the peroxisomal fluorescence signal under oleate containing medium is followed by a reduction on glucose containing medium. In contrast,  $\Delta$ Smnbr1 as well as  $\Delta$ Smatg8 displayed an unaltered fluorescence intensity under all conditions.

**Figure 31: Microscopic and quantitative investigations of proliferation of SmPEX14 EGFP-labeled peroxisomes.**

(A) The microscopic images illustrate the fluorescence as well as the corresponding DIC and merged images of SmPEX14-EGFP expressed in wt,  $\Delta$ Smnbr1 and  $\Delta$ Smatg8 strains. All strains were analyzed after 24 h growth on SWG, subsequent growth for 24 h on SWG-G+OA or 24 h after shifting the strains from the oleic acid containing media to SWG. For the wt strain, pictures with a higher exposure are shown and filled vacuoles are labeled with a white arrow. These pictures are representative examples for the quantitative analysis shown in (B). Scale bars are indicated. DIC, Differential interference contrast (B) For the quantification of SmPEX14-EGFP fluorescence signals, a defined area in a hyphae (length of 80  $\mu$ m) was analyzed and counted for EGFP signals with ImageJ. The diagram shows an average of 100 hyphal areas ( $n=100$ ) for each condition and strain. The standard deviations are indicated. The wt under SWG condition was set to 1.

Fluorescence microscopic pictures of wild type strain co-expressing SmPEX14-EGFP and SmNBR1-DsRED revealed an increased number of peroxisome clusters after induction of peroxisome proliferation on fatty-acid containing medium and the back shift to glucose containing medium. Whereas during the starting conditions on SWG medium, more single peroxisomes can be observed. Interestingly, after the medium shift multiple and also single peroxisomes were often decorated with SmNBR1-DsRED (Figure 32). In summary, in *S. macrospora* the degradation of surplus peroxisomes takes place in a SmNBR1-dependent manner.

**Figure 32: Co-localization studies of SmPEX14-EGFP clusters and SmNBR1-DsRED.**

The wt strain expressing SmPEX14-EGFP and SmNBR1-DsRED was analyzed by fluorescence microscopy after 48 h on SWG or after 24 h shifting the strains from SWG-G+OA medium w/o glucose instead containing 0.15 % oleic acid (OA) (growth for 24 h) to glucose containing medium (SWG). Proliferation of peroxisomes by the formation of cluster structures in response to fatty acids was visualized by peroxisomal membrane labeling with SmPEX14-EGFP. After shifting, the strain single and multiple peroxisomes were decorated with SmNBR1-DsRED indicated by arrows. Enlargements show representative co-localization of both proteins. Scale bars are indicated.

### 3.3.4 Functional analysis of Woronin bodies

Since peroxisomal degradation and turnover is associated with autophagy in *S. macrospora*, the absence of the autophagy marker protein SmATG8 or the selective cargo receptor SmNBR1 might also affect the function of Woronin bodies. The most abundant protein in this organelle is the matrix protein HEX1. To address whether the autophagy proteins SmNBR1 and SmATG8 are required for Woronin body degradation in *S. macrospora*, we examined SmHEX1-localization in  $\Delta$ Smnbr1 and  $\Delta$ Smatg8 mutants. For this, a plasmid was constructed which expresses an N-terminal *Dsred*-tagged version of *Smhex1* under control of the *trpC* promoter of *A. nidulans*. Wild type,  $\Delta$ Smatg8 and  $\Delta$ Smnbr1 *S. macrospora* strains were transformed with the plasmid pDsred-Smhex1. DsRED-SmHEX1 was localized to Woronin-bodies at septal pores and cytoplasm. To investigate the function of Woronin bodies in membrane sealing, hyphae were cut with a scalpel and analyzed 10 min after injury by fluorescence microscopy. In wild type hyphae, the Woronin bodies rapidly sealed the septal pore and thereby prevented the leakage of cytoplasm. After cutting, large puddles of cytoplasm leaked through the hyphal wound which is visible in DIC images (Figure 33). Under the same conditions the localization of DsRED-SmHEX1 in mutant strains  $\Delta$ Smnbr1 and  $\Delta$ Smatg8 was investigated. As in the wild type, the Woronin bodies were also able to seal the hyphae by plugging the septal pores in the mutant strains.

As control, we analyzed all these strains for the presence of DsRED-SmHEX1. For this, equal amounts of protein crude extracts were analyzed by SDS-PAGE and immunoblotting using an RFP antibody. The *S. macrospora* DsRED-SmHEX1 protein was detectable in wild type,  $\Delta$ Smatg8 and  $\Delta$ Smnbr1 strain (Figure 33B). Deletion of *Smnbr1* and *Smatg8* did not seem to disturb localization and functionality of Woronin bodies.

**Figure 33: Localization studies of DsRED-SmHEX1 in wt and autophagy mutants.**

(A) Fluorescence microscopy of DsRED-tagged Woronin bodies (SmHEX1) in wt,  $\Delta$ Smnbr1 and  $\Delta$ Smatg8 strains show localization at septal pores and in the cytoplasm. After growing of the strains for 24 h on covered slides, hyphae were cutted and observed under the microscope after 10 min. Some of the cutting fronts are exemplary labeled with a red open arrows. Septae were stained with calcofluor white. Merged images were assembled from either the fluorescence (red, blue) or the fluorescence and the differential interference contrast (DIC, red) micrographs. Scale bars are indicated. (B) Expression controls of DsRED-SmHEX1 in the same strains by Western-blot analysis of equal amounts of crude extracts using RFP antibody.

### 3.4 SmNBR1-dependent ribophagy in *S. macrospora*

In mammals and plants NBR1 acts as an autophagy receptor to target ubiquitinated substrates to the vacuole (Kraft et al. 2010). Since SmNBR1 does not contain an obvious UBA domain we aimed to identify interaction partners of SmNBR1.

#### 3.4.1 SmNBR1 interacts with ribosomal proteins

To detect possible interaction partners of SmNBR1 a GFP-Trap analysis coupled to liquid chromatography mass spectrometry (LC/MS) was performed with a strain expressing functional SmNBR1-EGFP as bait protein. The LC/MS data set was analyzed with Proteome Discoverer™ 1.4 (Thermo Scientific) software using the SequestHT search engine (Thermo Scientific). Only high confident proteins, with a threshold of minimum 2 peptides with a false discovery rate less than 0.01 were considered. To identify stringent interactors from the LC/MS raw data set, we included only those proteins that were trapped in two biological replicates and were absent from the control data set obtained from a GFP-Trap of an EGFP-expressing strain. Additionally, a label free quantification (LFQ) was performed with Perseus 1.5.1.0 software and only proteins were chosen which exhibit a t-test significance.

Interestingly, SmNBR1 GFP-Trap analysis revealed two proteins of the small and one large ribosomal subunit as well as the ribosomal associated protein STM1 (suppressor of *tom1*) within the first 8 best hits of the protein set (Table 7) leading to the assumption that SmNBR1 might be somehow involved in ribosome homeostasis.

**Table 7: Results of GFP-Trap and LC/MS analysis using SmNBR1-EGFP as bait protein.**

No. best hit	SMAC	name	function	significance t-test value
1	SMAC_07844	SmNBR1	selective cargo receptor	9.25e <sup>+08</sup>
2	SMAC_01302	SmRPS27	small ribosomal protein 27	6.92e <sup>+08</sup>
3	SMAC_04779	acetyl-CoA-acetyltransferase	fatty acid degradation enzyme	5.02e <sup>+08</sup>
4	SMAC_02849	saccharopine dehydrogenase	amino-acid biosynthesis	2.20e <sup>+08</sup>
5	SMAC_00402	pseudouridylate synthase	pyrimidine metabolism	2.13e <sup>+08</sup>
6	SMAC_07107	SmRPL28	large ribosomal protein 28	1.98e <sup>+08</sup>
7	SMAC_04909	SmRPS21	small ribosomal protein 21	1.94e <sup>+08</sup>
8	SMAC_05296	SmSTM1	associated with ribosomal proteins to stabilize these during starvation	1.89e <sup>+08</sup>

Therefore, ribosomal degradation was monitored *in vivo* using EGFP-tagged protein SmRPL25 for the large ribosomal subunit and protein SmRPS19 for the small ribosomal subunit. First, the two ribosomal EGFP-fusion proteins were analyzed by fluorescence microscopy in wild type,  $\Delta$ Smnbr1 and the autophagy defective  $\Delta$ Smatg8 strain.

Under rich conditions (BMM) SmRPL25-EGFP was concentrated in the nucleus (Supplement 7A) of young hyphae in the wild type strain but the EGFP signal accumulated in the cytoplasm and later in the vacuoles in older hyphae indicating that degradation takes place in an autophagy-dependent manner (Figure 34A). In the wild type, vacuolar degradation of SmRPL25-EGFP occurred faster under autophagy-inducing conditions (BMM + 2.5 mM 3-AT). In contrast, SmRPL25-EGFP was more stable over a time period in  $\Delta$ Smnbr1 and the EGFP signal appeared to be concentrated in the nucleus for a longer period under rich as well as under autophagy-inducing conditions. As expected, SmRPL25-EGFP was very stable and no vacuolar degradation was visible in the autophagy defective mutant  $\Delta$ Smatg8. Thus leading to the assumption that the large ribosomal subunit is degraded in a SmATG8 as well as SmNBR1 dependent manner (Figure 34C).

## Results

**Figure 34: Degradation of SmRPL25-EGFP under normal and starvation conditions.**

Wt, ΔSmnbr1 and ΔSmatg8 strains expressing SmRPL25-EGFP under the native promoter were grown under normal conditions (BMM) or autophagy-inducing conditions (BMM +2.5 mM 3-AT). (A) Fluorescence microscopy of SmRPL25-EGFP in the wt and mutant strains after 18, 48 and 72h of growth on rich medium. Arrows label filled vacuoles. Scale bar is indicated. (B) Quantitative Western-blot analysis of SmRPL25-EGFP in the same strains as in (A) grown in BMM rich medium for three to six days. Vacuolar EGFP cleavage was analyzed by Western blotting with an EGFP-antibody. ImageJ software was used to quantify the ratio between cleaved EGFP and the full-length protein. The last time point (6 d) of wt was set to 1. In the diagram the average of three independent experiments is shown and the standard deviations are displayed. As protein loading control the actin protein was detected using an actin-antibody. A wt strain expressing free EGFP was used as control for EGFP. (C) Strains were grown under autophagy-inducing conditions on BMM supplemented with 2.5 mM 3-AT and analyzed by fluorescence microscopy at the indicated time points. Arrows label filled vacuoles. Scale bar is indicated. (D) Quantitative Western-blot analysis of the ribosomal protein SmRPL25-EGFP in the same way as described in (B) under autophagy inducing conditions (BMM +2.5 mM 3-AT). DIC, Differential interference contrast. a.u., arbitrary unit. Scale bars are indicated.

The localization study of SmRPS19-EGFP by fluorescence microscopy revealed the same as for SmRPL25-EGFP, degradation took place in the wild type whereas a stabilization of SmRPS19-EGFP is visible in ΔSmnbr1 and the autophagy defective mutant ΔSmatg8 (Figure 35A+C). The localization of SmRPS19-EGFP in wild type strain to the nucleus is shown by

DAPI staining after 24h growth. Additionally, after 48h growth SmRPS19-EGFP and SmNBR1-DsRED were co-localized in the vacuole shown in the wild type strain expressing both proteins (Supplement 7B,C).

**Figure 35: Degradation of SmRPS19-EGFP under normal and starvation conditions.**

Wt, ΔSmbnr1 and ΔSmatg8 strains expressing SmRPS19-EGFP under the native promoter were grown under normal conditions (BMM) or autophagy-inducing (BMM +2.5 mM 3-AT) conditions. (A) Fluorescence microscopy of SmRPS19-EGFP in the wt and mutant strains after 18, 48 and 72h of growth on rich medium. Arrows label filled vacuoles. Scale bar is indicated. (B) Quantitative Western-blot analysis of SmRPS19-EGFP in the same strains on BMM rich medium for three to six days. Vacuolar EGFP cleavage was analyzed by Western blotting with an EGFP-antibody. ImageJ software was used to quantify the ratio between cleaved EGFP and full length protein. The last time point (6 d) of wt was set to 1. In the diagram the average of three independent experiments is shown and the standard deviation is displayed. As protein loading control the actin protein was detected using an actin-antibody. A wt strain expressing free EGFP was used as control for EGFP. (C) Strains were grown under autophagy-inducing conditions on BMM supplemented with 2.5 mM 3-AT and analyzed by fluorescence microscopy at the indicated time points. Arrows label filled vacuoles. Scale bar is indicated. (D) Quantitative Western-blot analysis of the ribosomal protein SmRPS19-EGFP in the same way as described in (B) under autophagy inducing conditions (BMM +2.5 mM 3-AT). DIC, Differential interference contrast. a.u., arbitrary unit. Scale bars are indicated.

As control, the localization of free EGFP was analyzed in wild type and  $\Delta$ Smnbr1 and showed an evenly distributed signal in the cytoplasm. Over the time, this signal was localized to the vacuole (Figure 36).

For the specific relocation of the ribosomal proteins into the vacuole a functional autophagy machinery is required and it seems that selective autophagy components like SmNBR1 are necessary.

**Figure 36: EGFP fluorescence localization in wt and  $\Delta$ Smnbr1.**

Wt and  $\Delta$ Smnbr1 strains expressing EGFP were analyzed by fluorescence microscopy after growth for 18, 48 and 72h on rich medium. Wt strain was transformed with plasmid p1783-1 and  $\Delta$ Smnbr1 with plasmid pDS23. DIC, Differential interference contrast. Scale bars are indicated.

To verify these fluorescence microscopic observations the transport of EGFP-tagged ribosomal proteins from the cytoplasm to the vacuole, was assayed by Western blot analyses of the degradation of the tagged protein and vacuolar accumulation of free EGFP. During vacuolar degradation the EGFP moiety is highly stable and can be monitored as free EGFP by Western blotting of total cell extracts (Kraft et al. 2008). Deletion of *Smnbr1* led to delayed cleavage of EGFP from the reporter protein SmRPL25-EGFP under normal growth conditions and is even much more delayed after induction of autophagy compared to wild type (Figure 34B,D).

In the autophagy mutant  $\Delta$ Smatg8 autophagic degradation of ribosomes is arrested. Therefore, a stable EGFP signal of the fusion protein and no free EGFP signal was detected in the Western blot. This indicated that the cargo receptor SmNBR1 is required for optimal degradation rates of the large ribosomal subunit.

In contrast to this, the Western blot analyses of SmRPS19-EGFP revealed no significant degradation differences in the wild type and  $\Delta$ Smnbr1 strain under rich and starvation

conditions (Figure 35B,D). Similar to SmRPL25, SmRPS19-EGFP was stabilized in the autophagy-defective mutant  $\Delta$ Smatg8, which indicated that also the small ribosomal subunit was degraded in an autophagy dependent manner. However, it seems that SmRPS19 was not a substrate for the selective cargo receptor SmNBR1.

To control the function of the bulk autophagy mechanism, the degradation of a cytosolic control protein EGFP-SmATG8 was also analyzed by Western blot experiments. For this the respective complementation strain  $\Delta$ Smatg8::egfp-Smatg8<sup>ect</sup> and the  $\Delta$ Smnbr1::egfp-Smatg8<sup>ect</sup> strain were used. Both strains had nearly the same degradation ratio of EGFP-SmATG8 (Figure 37).

**Figure 37: Quantitative Western-blot analysis of the autophagosomal reporter protein EGFP-SmATG8.**

(A)  $\Delta$ Smatg8 and  $\Delta$ Smnbr1 strains expressing EGFP-SmATG8 were analyzed under normal growth conditions (BMM) using anti-EGFP antibody. Total protein samples were taken at the indicated time points. One of three representative blots is shown. Anti-actin was used for an equal protein loading. A wt strain expressing free EGFP was used as control for EGFP. The diagram shows the average of three independent experiments with standard deviations. (B)  $\Delta$ Smatg8 and  $\Delta$ Smnbr1 strains expressing the same control protein were analyzed under autophagy inducing conditions (BMM + 2.5 mM 3-AT) in the same way as described in (A). a.u., arbitrary unit.

The localization of EGFP-SmATG8 was also analyzed by fluorescence microscopy in the same strains. SmATG8 localized in autophagosomes and in vacuoles. Thus, the protein behaved functional in both strains (Figure 25B) and general autophagy appeared to be not affected in the  $\Delta$ Smnbr1 strain.

To analyze whether the cargo receptor SmNBR1 can interact with SmRPL25 or SmRPS19 *in vivo*, we performed immunoprecipitation (IP) experiments in wild type strains expressing DsRED-tagged SmNBR1 together with either SmRPL25 or SmRPS19 tagged with EGFP. SmRPL25-EGFP could be immunoprecipitated together with SmNBR1-DsRED supporting the hypothesis for a direct or indirect interaction of both proteins (Figure 38A). In contrast, the SmRPS19-EGFP could not be purified together with SmNBR1-DsRED in the IP experiment (Figure 38B).

**Figure 38: Immunoprecipitation of SmNBR1 together with ribosomal proteins.**

(A) Immunoprecipitation using a wt strain expressing SmNBR1-DsRED and SmRPL25-EGFP. After purification of SmNBR1-DsRED the protein SmRPL25-EGFP could be detected using anti-EGFP in the Western-blot analysis. (B) IP as described in (A) but using a wt strain expressing SmNBR1-DsRED and SmRPS19-EGFP. SmRPS19-EGFP does not interact with SmNBR1. Untransformed wt strain, a wt strain expressing free EGFP and the respective wt strains expressing SmRPL25-EGFP and SmRPS19-EGFP, respectively, served as controls. The strains were grown for 3 d in rich medium (BMM). The crude protein extracts were prepared and analyzed using anti-GFP and anti-RFP antibodies.

This result together with the quantitative Western-blot experiments suggested that SmRPS19 and maybe 40S ribosomal subunits in general are no direct cargos of SmNBR1.

Additionally, SmRPL25 and SmRPS19 were tested in a yeast-two hybrid assay for direct interaction with the cargo receptor SmNBR1. Neither SmRPL25 nor SmRPS19 showed an interaction with SmNBR1 leading to the assumption that both proteins are no direct substrates of the cargo receptor (Supplement 8).

## 4. Discussion

### 4.1 SmATG12, a core autophagy protein

In contrast to ATG8 homologs, the function of the second UBL autophagy protein ATG12 has received much less attention in filamentous fungi. We previously have shown that the E1-like enzyme SmATG7, which presumably activates SmATG8 and SmATG12, is essential for viability in *S. macrospora*, whereas the UBL protein SmATG8 and its protease SmATG4 are involved in vegetative growth and sexual development (Nolting et al. 2009; Voigt et al. 2014). We therefore investigated the role of the second UBL protein SmATG12 in sexual development and perithecia formation in this filamentous ascomycete.

#### 4.1.1 The conserved autophagy-associated protein SmATG12 is unable to rescue the *S. cerevisiae* atg12 $\Delta$ mutant

Sequencing of the Smatg12 cDNA verified the presence of a C-terminal glycine in the reduced amino-acid sequence of SmATG12 that is essential for the formation of an isopeptide bond with ATG5 (Mizushima et al. 1998) and was only reported to be absent in the *Plasmodium falciparum* ATG12 ortholog (Kitamura et al. 2012). In addition, the carboxy-terminal region (aa 72-159) of SmATG12 revealed a high degree of sequence identity when compared with ATG12 homologs from *S. cerevisiae*, plants and animals (Figure 8). This region of SmATG12 was predicted to form an ATG12 ubiquitin-like domain (APG12\_C, cd00196) by both the NCBI Conserved Domain Search tool (Marchler-Bauer et al. 2015) and InterProScan (PF04110) (Jones et al. 2014). Within this domain, several amino acids and a turn-loop-alpha helix 2 segment, previously shown in *S. cerevisiae* and *H. sapiens* ATG12 to be important for non-covalent interactions with ATG5, were found to be conserved in SmATG12 (Noda et al. 2013; Otomo et al. 2013). In *S. macrospora*, SMAC\_08343 encodes a 366 aa ATG5 ortholog that is larger than human or yeast ATG5 due to insertions, but it contains a conserved lysine residue (K218) that may form a conjugate with the C-terminal SmATG12 glycine residue (Supplement 1). Yeast-two hybrid analysis revealed that SmATG12 can interact with SmATG7, which was previously shown to display characteristic features of E1-like enzymes (Nolting et al. 2009) (Figure 9A). In yeast and mammals, ATG7 activates ATG12 via C-terminal adenylation, and subsequently a conserved cysteine residue is covalently linked via a thioester bond to the C-terminal glycine residue. A similar mechanism may therefore operate in *S. macrospora*.

After conjugation to ATG5, the ATG12~ATG5 conjugate acts in a complex with the coil-coiled protein ATG16 as an E3 ligase to conjugate ATG8 and PE (Figure 3). The ATG12~ATG5-ATG16 complex stimulates the transfer of ATG8 from the E2-like enzyme ATG3 to PE (Hanada and Ohsumi 2005; Noda et al. 2013; Sakoh-Nakatogawa et al. 2013). Analysis of the human ATG12 protein structure showed that it binds a short peptide region of ATG3 (Metlagel et al. 2013). Only some of these residues involved in this interaction are conserved in SmATG12. However, yeast-two hybrid analysis confirmed the interaction of SmATG12 and SmATG3 (Figure 9B). In humans, a fraction of ATG3 was found to be conjugated to ATG12 via lysine 243 (K243) (Radoshevich et al. 2010), which is also conserved in SmATG3 (Supplement 2). Therefore, conjugation of SmATG3 and SmATG12 may also be of physiological relevance in *S. macrospora*.

Two residues responsible for mimicking a non-canonical LIR in ATG12 are conserved in SmATG12 (Figure 8) (Kaufmann et al. 2014). However, an interaction of SmATG12 and SmATG8 could not be demonstrated in the yeast-two hybrid analysis (Figure 9C). This might be explained by non-efficient lipidation of SmATG8 in yeast.

Even though *S. macrospora* SmATG12 has many conserved features, the *Smatg12* cDNA was unable to complement the *S. cerevisiae* *atg12* $\Delta$  mutant. Interestingly, this was also the case when *A. thaliana* ATG12 orthologs were tested in *S. cerevisiae* (Hanaoka et al. 2002). We previously showed that *Smatg7*, *Smatg8* and *Smatg4* all complemented the autophagy defects of their corresponding yeast mutants (Nolting et al. 2009; Voigt and Pöggeler 2013a). The amino-acid sequence identity shared between SmATG7, SmATG8 and SmATG4 and their *S. cerevisiae* homologs is 53 %, 76 % and 43 %, respectively. In contrast, the sequence identity of SmATG12 and *S. cerevisiae* Atg12 is only 20 %. In particular, the N-terminal region of SmATG12 is conserved only among filamentous ascomycetes. Therefore, structural differences might prevent functional complementation of the yeast mutant.

#### **4.1.2 SmATG12 is required for sexual reproduction and normal vegetative growth**

Similar to the autophagic core components SmATG8 and SmATG4, deficiency of SmATG12 led to a reduced vegetative-growth rate and insufficient foraging under nutrient-limiting conditions, as well as the arrest of fruiting-body development at the early protoperithecius stage under nutrient-rich conditions (Figure 15) (Voigt and Pöggeler 2013a). In contrast to  $\Delta$ *Smatg8* and  $\Delta$ *Smatg4*, a significant decrease in growth rate occurred only when starvation

was induced by 3-AT (Figure 15C). Similarly, budding yeast *S. cerevisiae* and plant *atg12* mutants exhibited reduced viability only under starvation conditions (Tsukada and Ohsumi 1993; Chung et al. 2010; Li et al. 2015).

Although, deletion of *Smatg12* abolished fruiting-body formation and ascosporeogenesis even under nutrient-rich conditions, we were able to isolate a homokaryotic  $\Delta$ *Smatg12* knockout strain from the heterokaryotic primary transformant. This demonstrates that in contrast to the E1-like enzyme SmATG7 loss of SmATG12 is not detrimental to viability or essential for ascospore germination (Nolting et al. 2009). In *S. cerevisiae* and the fission yeast *S. pombe*, *atg12* deletion mutants also displayed disrupted ascosporeogenesis, but only during nitrogen starvation (Tsukada and Ohsumi 1993; Mukaiyama et al. 2009). Gene expression in *S. macrospora* undergoes significant differences during fruiting-body development (Teichert et al. 2014), suggesting extensive *de novo* protein synthesis is required for fruiting-body maturation and ascospore formation. Defects in autophagy may result in a shortage of recycled amino acids and hence proteins that are critical for sexual development. Deletion of *atg12* genes in a filamentous fungus have only been reported for *N. crassa* and the plant pathogen *M. oryzae* (Kershaw and Talbot 2009; Chinnici et al. 2014). The *N. crassa*  $\Delta$ *Ncatg12* mutant was able to initiate female development by producing ascogonia, and few small protoperithecia. Protoperithecia grafting experiments demonstrated that autophagy is required within the vegetative mycelium, because fertilized protoperithecia of *N. crassa*  $\Delta$ *Ncatg12* mutants grafted onto a wild type mycelium were able to complete fruiting-body development and produced ascospores (Chinnici et al. 2014). The *M. oryzae*  $\Delta$ *Moatg12* strain was nonpathogenic and defective in appressorium formation, but effects on fruiting-body development were not reported (Kershaw and Talbot 2009). ATG12-defective plants developed normally but displayed premature senescence, produced less seeds under nutrient-rich conditions, and were hypersensitive to carbon and nitrogen starvation (Chung et al. 2010; Li et al. 2015). Similarly, knockdown of *atg12* in the protozoan parasite *Acanthamoeba castellanii* resulted in the inhibition of cyst formation (Kim et al. 2015). Together, these results suggest that *Smatg12*-dependent autophagy may play an important role in *S. macrospora* development.

### 4.1.3 Deletion of *Smatg12* abolishes delivery of EGFP-labeled SmATG8 to the vacuole

The EGFP-SmATG8 proteolysis assay revealed that SmATG12 is required for proper autophagic degradation of an EGFP-SmATG8 fusion protein (Figure 14). Furthermore, fluorescence microscopy of the functional EGFP-SmATG12 fusion protein revealed localization in bright foci and cup-shaped structures that were presumed to be the PAS and growing phagophores, respectively (Figure 16A). In *S. cerevisiae* and mammalian cells, ATG5 and ATG16 are markers for phagophores (also known as isolation membranes) (Mizushima et al. 2001; Mizushima et al. 2003; Suzuki et al. 2013). Both are components of the ATG12~ATG5-ATG16 complex that acts as an E3 enzyme for the efficient lipidation of ATG8 (Hanada et al. 2007). In a reconstituted *in vitro* system using giant unilamellar vesicles and recombinant proteins the complex was shown to tether vesicular precursors during phagophore elongation, in addition to its E3 function (Romanov et al. 2012).

In *S. cerevisiae*, the ATG12~ATG5-ATG16 complex is believed to be recruited to the PAS and to remain at the phagophore during expansion before detaching upon completion of autophagosome formation (Suzuki et al. 2013). In accordance with these observations, we did not observe any labeling of mature autophagosomes or vacuoles in the strain expressing EGFP-SmATG12 (Figure 16A). Only a small portion of the ATG12~ATG5-ATG16 complex localizes to the PAS and the phagophore whereas the majority of the complex is reported to be localized to the cytoplasm (Mizushima 2004). Besides its function in autophagy and its association in the ATG12~ATG5-ATG16 complex, ATG12 carries out autophagy-independent roles. After conjugation to ATG3, it is involved in mitochondrial homeostasis, endosomal trafficking and apoptosis, whereas free ATG12 associates with anti-apoptotic Bcl-2 to promote mitochondrial apoptosis (Radoshevich et al. 2010; Rubinstein et al. 2011; Murrow et al. 2015). The exact localization of ATG12 during these processes remains to be determined.

When expressing EGFP-SmATG12 in an autophagy-deficient  $\Delta$ *Smatg8* mutant, the number of fluorescent foci appeared to increase and cup-shaped structures were not detected (Figure 16B). The enhanced localization of SmATG12 to these PAS-like structures may be explained by the blocking of phagophore extension due to the absence of SmATG8.

In the  $\Delta$ *Smatg12* mutant, the EGFP-SmATG8 reporter was localized to a few small dot-like structures and large fluorescent aggregates in the cytoplasm (Figure 16D). This finding is in agreement with our previous findings in which expression of EGFP-SmATG8 in a  $\Delta$ *Smatg4* mutant resulted in the formation of large aggregates instead of small punctate autophagosomes

(Voigt and Pöggeler 2013a). Aggregates of a YFP-ATG8 reporter protein have been identified in a maize *atg12* mutant, and electron microscopy revealed these aggregates to be amorphous structures lacking a delineating membrane but containing the YFP-ATG8 reporter protein and ubiquitin (Li et al. 2015). In mice, ATG8 tended to aggregate in an autophagy-independent manner (Kuma et al. 2007), and autophagosomes in other organisms failed to form when components of the ATG12~ATG5-ATG16 complex were deleted (Mizushima et al. 1998; Mizushima et al. 1999; Mizushima et al. 2001; Suzuki and Ohsumi 2010). A fluorescence signal from EGFP-SmATG8 was not detected in the vacuoles of the  $\Delta$ Smatg12 mutant, indicating that ATG8-mediated autophagy was affected (Figure 16D).

In conclusion, SmATG12-mediated autophagy appears to be essential for fruiting-body formation and the production of ascospores in *S. macrospora*. Furthermore, SmATG12 was localized to phagophore structures in a SmATG8 dependent manner.

## **4.2 The selective autophagy cargo receptor SmNBR1**

Beside the non-selective bulk autophagy, selective autophagy is characterized by cargo receptor proteins such as NBR1, which are able to bind a specific cargo including organelles, proteins or microbes for their autophagic degradation. The selective type of autophagy has not been exhaustively analyzed in filamentous fungi yet (Kimura et al. 2011; Shoji and Craven 2011; Voigt and Pöggeler 2013b; Chinnici et al. 2014).

In a study to identify new interaction partners of the core autophagy protein SmATG8 we performed a GFP-Trap analysis with EGFP-SmATG8. Among other interaction partners a putative homolog of the mammalian selective cargo receptor NBR1 (neighbor of BRCA1) was identified, which we therefore named SmNBR1 (Figure 5). Since, SmNBR1 is not encoded in *S. cerevisiae* and not yet analyzed in filamentous fungi we investigated its function in the ascomycete *S. macrospora*.

### **4.2.1 SmNBR1 has a conserved domain architecture**

The domain architecture of SmNBR1 is conserved within filamentous ascomycetes. Amino-acid alignments revealed that the domain structure of SmNBR1 is very similar to that of orthologs of filamentous ascomycetes, including the lack of the C-terminal UBA domain, commonly found in plant and mammalian homologs, and the presence of a C-terminal conserved region, specific to fungal homologs (Figure 18). Apart from that, SmNBR1 displays many similarities to its plant and mammalian homologs, particularly in the N-terminal PB1

domain, several ZZ-type zinc-finger domains, coiled-coil domains, the name giving NBR1 box and the C-terminal LIR motif for ATG8 interaction. The functionally uncharacterized NBR1 box domain is conserved in all NBR1-like proteins and not present in p62 (Kraft et al. 2010). The sequence identity of SmNBR1 and *H. sapiens* NBR1 is 22 %. We showed that *Hsnbr1-Dsred* could be expressed in *S. macrospora* and it is able to partially rescue the phenotypical defects of  $\Delta$ Smnbr1. However, we conclude that SmNBR1 is the homolog to the mammalian NBR1 protein. Additionally, these findings strongly support the previous phylogenetic analysis of NBR1 homologs in eukaryotes performed by Kraft et al. (2010) where autophagy cargo receptors of filamentous ascomycetes and basidiomycetes, are characterized by the absence of UBA and other ubiquitin-binding domains (Figure 18, Figure 21).

Interestingly, the NBR1 homolog in fission yeast is characterized only by the NBR1-box, and three ZZ-type domains. In addition, the NBR1-box of the *S. pombe* NBR1 displays only a weak conservation because only two of four tryptophan residues are conserved. It lacks the N-terminal PB1 domain and the C-terminal regions including the CR, UBA domain and the LIR motif (Mizushima 2015).

The mammalian and plant NBR1 proteins bind ubiquitinated cargos via their UBA domain. As mentioned, SmNBR1 has no obvious UBA domain and Western-blot experiments using anti-ubiquitin antibody revealed no distinct accumulation of ubiquitinated proteins in the  $\Delta$ Smnbr1 strain. In addition to ubiquitin mediated selective autophagy, cellular cargos can be delivered for autophagy independently of ubiquitin. The Cvt pathway in yeast presents one example where the enzymes Ape1 and Ams1 are recognized by the receptors Atg19 and Atg34 to form the Cvt complex (Lynch-Day and Klionsky 2010). The Cvt pathway is not found in filamentous fungi. Similarly, the mammalian selective autophagy receptors BNIP3 (Bcl2/E1B 19 kDa-interacting protein 3), NIX (known as BNIP3L) and FUNDC1 (FUN14 domain-containing protein 1) do not use ubiquitin modifications as a degradation signal. All three receptors are mitochondrial outer membrane proteins which can directly link mitochondria to autophagosomal membranes via their LIR motif (Mazure and Pouyssegur 2010; Novak et al. 2010; Liu et al. 2012).

Analogous to the mammalian NIX, the mitochondrial anchored mitophagy receptor Atg32 links damaged mitochondria to autophagosomal membranes in an ubiquitin-independent manner in *S. cerevisiae* (Okamoto et al. 2009).

The pexophagy receptors Atg30 of *P. pastoris* and Atg36 of *S. cerevisiae* bind Pex3 directly at the peroxisomal membrane under peroxisome-proliferation conditions without ubiquitin (Farre

et al. 2008). Burnett et al. (2015) identified a distinct Atg30-binding domain in *P. pastoris* Pex3 that modulates the phosphorylation status of the receptor and therefore its binding efficiency. Another mode of ubiquitin-independent cargo binding involves direct recognition of lipids, sugars or proteins exposed on targets. These signals should be presented and recognized only under starvation or stress conditions to protect cellular material from harmful components (Chu et al. 2013).

Currently, we do not know how SmNBR1 recognizes and degrades its cargo in selective autophagy. However, we may speculate that the CC domains of SmNBR1 are involved in receptor cargo interaction. All fungal NBR1 homologs contain two conserved CC domains similar to mammalian NBR1. In contrast, plant NBR1 homologs harbor no CC domains (Figure 18). Proteins containing CC domains play various biological roles, where the CC region can act as either a structural or interacting component, or both (Zhang et al. 2009; Munro 2011). For instance, the yeast cargo receptor Atg19 of the Cvt pathway specifically binds to the Ape1 protein via its CC domain (Shintani et al. 2002).

In addition to the CC domains fungal NBR1 homologs contain a C-terminal CR motif with similarity to a C-terminal Atg11-binding site in the yeast Atg19 receptor. Both domains, CR region and the Atg11-binding site, are localized N-terminally of the LIR motif and are characterized by conserved serine residues, presumably for phosphorylation or activation. In *S. cerevisiae* it was shown that the scaffold protein Atg11 binds to this serine-rich region of Atg19. Further, phosphorylation of the Atg11-binding site by the kinase Hrr25 promotes Atg19-Atg11 interaction and initiates autophagosome formation (Pfaffenwimmer et al. 2014). The presence of a conserved serine-rich fungal specific CR region suggests that the yeast Atg19 protein is possibly an ortholog of fungal NBR1. Additionally, the Atg19 receptor, similar to SmNBR1, interacts with Atg8 via its LIR motif, characterized by the amino-acid motif WxxL and it does not contain a UBA domain (Noda et al. 2008; Kraft et al. 2010). Despite these common features no significant sequence homology exists between the yeast receptor Atg19 and SmNBR1 (Sawa-Makarska et al. 2014).

#### **4.2.2 SmNBR1 and SmATG8 are direct interaction partners which interact via the LIR motif of SmNBR1**

All protein characteristics indicate that SmNBR1 might act as a selective cargo receptor. Based on known cargo receptor functions, we tested the hypothesis of the involvement of SmNBR1 in autophagy, including autophagosome formation and degradation in the vacuole, by fluorescence microscopy. Cellular localization studies using functionally expressed SmNBR1-EGFP/DsRED fusion proteins revealed that SmNBR1 was localized in the cytoplasm as small dots, presumably representing autophagosomes, and in vacuoles, indicating degradation of SmNBR1 (Figure 24A, Supplement 5). Similarly, localization studies of NBR1 in plants and mammals showed the formation of cytosolic bodies described as punctate structures (autophagosomes) and a localization to the central vacuole or lysosome by autophagy (Kirkin et al. 2009; Svenning et al. 2011; Zientara-Rytter et al. 2011; Zhou et al. 2013). Fluorescence microscopy studies of EGFP-SmATG8 and SmNBR1-DsRED showed co-localization of both proteins in autophagosomes-like structures and in the vacuole. We confirmed the direct interaction of SmNBR1 and SmATG8 via GFP-Trap analysis, Co-IP, yeast-two hybrid and BiFC assays. By the yeast-two hybrid analysis, we limited the region of SmNBR1 necessary for the interaction with SmATG8 to the presence of a functional LIR motif at the C-terminus. This confirms the homology of the protein to its mammalian and plant homologs (Figure 24). In mammals and plants, it has been shown that a number of cargo receptors, including NBR1, bind directly to ATG8-family proteins via the LIR motif (Pankiv et al. 2007; Ichimura et al. 2008; Johansen and Lamark 2011; Svenning et al. 2011). For mammalian NBR1, it was found that the LIR motifs are the major interaction surface for interaction with ATG8-like proteins, as mutations in the LIR motif caused a failure in the interaction with ATG8 (Kirkin et al. 2009; Lamark et al. 2009). Furthermore, yeast-two hybrid interaction studies of human NBR1 and ATG8 family proteins provide a detailed explanation of how the C-terminal sequence (aa 691-966) of NBR1 can interact with ATG8 (Kirkin et al. 2009). Studies using yeast-two hybrid analysis, pull-down experiments and mutation analysis with the plant homologs *A. thaliana* NBR1 and *Nicotiana tabacum* Joka2 also showed that NBR1-ATG8 interaction is limited to the LIR motif (Svenning et al. 2011; Zientara-Rytter et al. 2011).

### 4.2.3 The *S. macrospora* SmNBR1 is required for proper sexual development, vegetative growth and stress resistance

Autophagy plays diverse roles in biological processes of filamentous ascomycetes including sexual development, viability and vegetative growth (Voigt and Pöggeler 2013b; Teichert et al. 2014). The putative *S. macrospora* homolog of the selective autophagy cargo receptor NBR1 is also involved in developmental processes as well as starvation and stress response in *S. macrospora*.

Initially, the *Smnbr1* knockout strain showed defects in late stages of fruiting-body development and displayed an impaired vegetative growth. The mutant formed ascogonia, protoperithecia and perithecia but in a reduced number and after a prolonged time. The ascus rosettes of the mutant harbored incomplete asci with few mature ascospores (Figure 20). Consequently, the number of discharged mature ascospores, which are essential for reproduction, was also drastically reduced. These effects are more pronounced under starvation and stress-inducing conditions when compared to the wild type. In *S. macrospora*, studies of autophagy-deficient  $\Delta$ *Smatg8*,  $\Delta$ *Smatg4* and  $\Delta$ *Smatg12* mutants displayed a sterile phenotype in combination with defects in vegetative growth and starvation intolerance and deletion of *Smatg7* is even lethal (Nolting et al. 2009; Voigt and Pöggeler 2013a; Werner et al. 2016). Previous analysis of the selective autophagy process in *A. thaliana* showed that disruption of the *nbr1* gene caused impairment in autophagosome formation and the mutant was hypersensitive to oxidative, drought and salt stresses. The  $\Delta$ *Atnbr1* as well as the tomato NBR1a/NBR1b silencing strain showed an increased sensitivity to heat stress by accumulating ubiquitinated substrates in cells. Autophagy-defective mutant- or transgenic plants showed extensive wilting and drought stress symptoms and seedlings were not salt tolerant. A knockout of the NBR1 homolog Joka2 in *N. tabacum*, could not be generated but analysis showed an apparently induction of the gene expression of JOKA2 and ATG8 in the roots when plants were grown in either N- or S-deficiency (Zientara-Rytter et al. 2011; Zhou et al. 2013; Zhou et al. 2014a). Similarly, in *S. macrospora* deletion of the *Smnbr1* caused increased sensitivity to starvation and stress conditions, and impaired development of sexual structures.

To determine whether the role of SmNBR1 in starvation and stress conditions is due to its action as an autophagy cargo receptor, we performed genetic complementation of  $\Delta$ *Smnbr1* with the wild type *Smnbr1* gene (ectopically integrated). Transformants expressing the wild type *Smnbr1* gene almost fully restored the starvation and stress tolerance of the mutant (Figure 28). Interestingly, complementation analysis of  $\Delta$ *Smnbr1* with truncated versions of SmNBR1 could

not improve the formation of perithecia and mature ascospores. These results indicate that a complete SmNBR1 protein is required for developmental processes and sexual spore production but this is just partly true for mutated versions of SmNBR1. The SmNBR1 versions without or a mutated LIR motif including the residues T<sup>843</sup>A, Y<sup>847</sup>A and L<sup>850</sup>A, have not the ability to fully complement the  $\Delta$ Smnbr1 defects. Therefore, it can be concluded that these residues are important for the function of the LIR motif. The exchange of the serine residues to alanine residues in the conserved region showed less defects in complementation strains, leading to the assumption that the CR domain is not essential for SmNBR1 function.

In autophagy-defective  $\Delta$ Smatg8,  $\Delta$ Smatg4 and  $\Delta$ Smatg12 strains, SmNBR1 forms cytoplasmic aggregates but is not delivered to the vacuole. Therefore, damaged and useless organelles or cellular proteins might be still targeted by SmNBR1 but not degraded in an autophagy-dependent manner and therefore accumulate at high levels as insoluble cytoplasmic aggregates (Figure 25A). The same has been shown in autophagy-defective plants and mammals, where endogenous AtNBR1 and NBR1, respectively, accumulated in the cytoplasm (Goldberg 2003; Komatsu et al. 2006; Kirkin et al. 2009; Svenning et al. 2011).

#### 4.2.4 SmNBR1 has many putative phosphorylation sites

Selective autophagy pathways are regulated by phosphorylation. In *S. cerevisiae*, the cargo receptors Atg30, Atg32, Atg36, Atg34 and Atg19 are phosphorylated under mito- and pexophagy-inducing conditions (Farre et al. 2013; Kanki et al. 2013). While the kinase CK2 regulates Atg32 function, the kinase Hrr25, a homolog of casein kinase 1 $\delta$  (CK), phosphorylates Atg19, Atg34 and Atg36 to initiate the Cvt pathway and pexophagy, respectively, by promoting their interaction with Atg11 (Pfaffenwimmer et al. 2014; Tanaka et al. 2014).

In mammals, random bulk autophagy is regulated by the phosphoinositide 3-kinase (PI3K). Selective autophagy is controlled by phosphorylation of the cargo receptor SQSTM1/p62 by CK2, which increases the affinity of the receptor to polyubiquitin chains and consequently to target proteins for their autophagic degradation (Matsumoto et al. 2011). Moreover, the mammalian NBR1 protein is phosphorylated at T<sup>586</sup> by kinase GSK3, which regulates its function as cargo receptor (Nicot et al. 2014).

The program NetPhos3.1 predicted 113 potential phosphorylation sites in SmNBR1 comprising 56 serine, 45 threonine and 12 tyrosine residues. These include amino-acid residues T<sup>843</sup> and Y<sup>847</sup> of the LIR motif, which were predicted to be substrates of the kinases CK2 and SRC, respectively. Additionally, the residues S<sup>793/804/808</sup> of the conserved region could be identified

as substrates of the kinases DNAPK (phosphatidylinositol-3-kinase related kinase) and GSK3. Other putative sites were predicted to be targets of CK2 or the cyclin dependent kinase 5 (CDK5).

By Western-blot analysis, several bands of SmNBR1-DsRED were detected, using an anti-RFP antibody suggesting that SmNBR1 is indeed subjected to posttranslational modifications. Moreover, phosphatase treatment reduced the number of additional bands in the Western blot (Figure 27). Thus, it can be assumed that SmNBR1 is modified by phosphorylation similar to other NBR1 homologs or other cargo receptors active in selective autophagy processes. Similarly, in mammals and plants phosphorylated NBR1 often migrates at other sizes than their predicted molecular weight. Commercial antibodies targeted against mammalian full-length NBR1 mostly recognize several bands around 150 kDa despite a theoretical size of 108 kDa for the longest isoform of NBR1 (Kirkin et al. 2009; Nicot et al. 2014). The same result is observable for the plant NBR1 homolog which shows several bands in Western-blot experiments (Zhou et al. 2013).

#### **4.2.5 In *S. macrospora*, pexophagy depends on SmNBR1**

Beside the fact that peroxisomes are essential for fatty acid  $\beta$ -oxidation and detoxification of reactive oxygen species (ROS) they have special functions in filamentous fungi. Fungal mutants lacking peroxisomes fail to grow on media containing fatty acids as sole carbon source (Erdmann et al. 1989; Hynes et al. 2008). Peroxisomes are also responsible for the biosynthesis of biotin and the formation of secondary metabolites including the biosynthesis of penicillins, polyketides, terpenes and paxilline (Maggio-Hall et al. 2005; Saikia and Scott 2009; Imazaki et al. 2010; Bartoszewska et al. 2011; Tanabe et al. 2011). Additionally, peroxisomes are involved in plant pathogenicity (Kimura et al. 2001; Asakura et al. 2006), sexual development and growth (Bonnet et al. 2006; Managadze et al. 2007; Peraza-Reyes et al. 2008).

The selective degradation of peroxisomes via autophagy depends in *P. pastoris* on Atg30 and in *S. cerevisiae* on Atg36 (Farre et al. 2008; Motley et al. 2012; Tanaka et al. 2014), but homologs of these proteins are not present in *S. macrospora* (Table 1). The *P. pastoris* cargo receptor Atg30 localizes to the peroxisomal membrane by binding to Pex3 and Pex14. It gets phosphorylated and upon induction it interacts with core autophagy components Atg11, Atg17 and Atg8. As additional protein Atg37 is involved in the assembly of a receptor protein complex. It has been suggested that the acyl-CoA binding protein Atg37 facilitate the Atg30-Atg11 interaction (Nazarko et al. 2014). In *S. cerevisiae*, Atg36 is recruited to peroxisomes by

Pex3 and is specifically required for pexophagy by indirect binding to Atg8 with the help of the scaffold protein Atg11 (Figure 39A).

In plants, it is speculated that NBR1 plays a role in pexophagy during heat stress because an over-accumulation of catalases in aggregates of an *A. thaliana* *Atnbr1* mutant could be observed (Zhou et al. 2014b; Young and Bartel 2016). However, the direct involvement of plant NBR1 in pexophagy was not experimentally verified so far. It is speculated that a selective autophagy receptor binds to the peroxisome as well as to ATG8, thus connecting the organelle to the autophagy machinery. The binding signal, which is recognized by the selective receptor, has not been identified yet but candidates include ubiquitinated proteins such as PEX5 or a matrix protein such as PEX3 or PEX14 (Young and Bartel 2016) (Figure 39B).

Further, NBR1 and its partner p62 are involved in the selective degradation of peroxisomes in mammals (Kirkin et al. 2009; Deosaran et al. 2013). It was shown, that NBR1 is necessary and sufficient for pexophagy to maintain a healthy peroxisome population (Deosaran et al. 2013). In mammals, three different types of peroxisome degradation have been reported so far (Hara-Kuge and Fujiki 2008; Kim et al. 2008; Deosaran et al. 2013; Yamashita et al. 2014). First, pexophagy can be induced by recognition of a ubiquitinated unknown peroxisomal protein by p62, which bridges the ubiquitin-decorated peroxisome with the developing autophagosomes via LC3-II (ATG8) (Kim et al. 2008). Secondly, under nutrient-starvation conditions the peroxisomal membrane protein PEX14 prefers to bind directly to LC3-II (ATG8) in a competitive manner with PEX5 (Hara-Kuge and Fujiki 2008) (Figure 39C). Thirdly, Deosaran et al. (2013) showed that pexophagy is also induced by overexpression of NBR1, which promotes peroxisome clustering around NBR1 and autophagic peroxisome degradation. Moreover, mono-ubiquitinated PEX5 and overexpression of PEX3 target NBR1 to clustered peroxisomes (Deosaran et al. 2013; Yamashita et al. 2014).

**Figure 39: Mechanistic views of receptor-dependent pexophagy pathways.**

(A) The phosphoprotein Atg30, identified in the yeast *P. pastoris*, is the receptor for pexophagy. This protein can interact with the peroxisomal membrane protein Pex3/Pex14 and/or Atg37 and becomes phosphorylated during pexophagy (yellow star). Atg30 interacts with the autophagy-adaptor proteins Atg11 and Atg17 at the pexophagy specific PAS. Together with Atg8 it is required for the formation of the phagophore membrane that engulfs peroxisomes. Another receptor is Atg36 identified in *S. cerevisiae*. Atg36 is anchored to the peroxisome by its association with Pex3 and after phosphorylation it also interacts with Atg11 and Atg8. (B) In plants, it is postulated that an autophagy cargo receptor binds to the peroxisome and to Atg8, connecting the degrading peroxisome to the autophagy machinery. The signal on plant peroxisomes for the selective autophagy receptor has not been identified. Candidates include ubiquitinated proteins such as the peroxisomal targeting receptor Pex5 or membrane proteins Pex3 or Pex14. (C) Peroxisomes can be targeted by p62-mediated detection of ubiquitin motifs on still unknown peroxisomal membrane proteins or by a direct binding of Atg8 (LC3-II) to Pex14 in a Pex5-competitive manner. When the mammalian peroxisomal import receptor Pex5 is recruited to the peroxisomal membrane ubiquitination takes place. The mono-ubiquitinated Pex5 is a target of Nbr1, which in turn interacts with Atg8 at the PAS. Additionally, overexpression of Pex3 can target NBR1 to clustered peroxisomes. (D) In *S. macrospora*, the hypothetical mechanism of peroxisome targeting is dependent on a selective cargo receptor, possibly SmNBR1 (Nbr1), which interacts with Atg8 at the PAS. But the target protein at the peroxisomal membrane is unknown. SmNBR1 may either directly target a peroxisomal membrane protein or an additional protein is interposed. (E) The phagophore completely encloses its cargo forming an autophagosome, which is delivered to the vacuole or lysosome to form the autophagic body. The whole content is degraded and building blocks are released into the cytosol for reuse. Ub, ubiquitin; PAS, phagophore assembly site; P, phosphorylation.

Detailed studies of the mammalian NBR1 demonstrated that the amphipathic  $\alpha$ -helical J domain (JUBA), the ubiquitin-binding UBA domain, the LIR motif and the CC domain are essential to mediate pexophagy. NBR1 uses a mechanism where the combination of the UBA domain and

the membrane interacting J domain are involved, to bind to the peroxisomal lipid bilayer (Deosaran et al. 2013).

The plant NBR1 homologs from *N. tabacum* and *A. thaliana* contain UBA1 and UBA2 domains (Figure 18). It has been shown that only UBA2 can bind ubiquitin *in vitro* (Svenning et al. 2011) and the UBA1 domain is capable to form an amphipathic helix. Therefore, it was attempting to speculate that this region might have a similar role as the JUBA domain of human NBR1 (Zientara-Rytter et al. 2011). However, it seems that the JUBA domain is specific for animal NBR1 (Mardakheh et al. 2010) because a similar domain could not be found in plants and fungi. The NBR1 homolog in *S. macrospora* is an attractive fungal candidate for a pexophagy receptor (Figure 39D). In this study we demonstrated that the *S. macrospora*  $\Delta$ Smnbr1 strain is not able to use fatty acids as sole carbon source and  $\Delta$ Smnbr1 is not able to form fruiting bodies on medium containing H<sub>2</sub>O<sub>2</sub> (Figure 29). Therefore, it may be suggested that SmNBR1 is involved in the turnover of viable peroxisomes. By fluorescence microscopy it was shown that the degradation of the peroxisomal reporter protein DsRED-SKL is arrested in  $\Delta$ Smnbr1 compared to the wild type (Figure 30). The peroxisomal marker protein SmPEX14 was additionally analyzed by fluorescence localization studies in wild type,  $\Delta$ Smnbr1 and  $\Delta$ Smatg8 strains. When compared to the wild type, peroxisomes changed in size, number and morphology in  $\Delta$ Smnbr1 and  $\Delta$ Smatg8 strains (Figure 31). The protein or signal that labels peroxisomes for their degradation is not identified in *S. macrospora* so far. SmNBR1 contains a LIR motif for binding to SmATG8 but the UBA domain is missing for binding to ubiquitin or an ubiquitinated substrate as described for pexophagy in mammals.

#### 4.2.6 Woronin bodies are functional in autophagy-defective mutants

Woronin bodies are peroxisome-derived organelles of filamentous fungi. They function as a plug of septal pores after hyphal wounding to prevent the loss of cytoplasm at sites of injury. The dominant protein of this organelle is HEX1 which forms hexagonal crystals *in vitro* and is localized to the matrix of the Woronin bodies in large and stable complexes (Jedd and Chua 2000). Deletion of HEX1 has been described to lead to impairment of Woronin body biogenesis and results in diverse effects in cellular and developmental processes. In *N. crassa*, *A. oryzae* and *M. grisea*, *hex1* deletion strains show extensive cytoplasmic loss after hyphal lesions. In *N. crassa*, HEX1 is described as a very stable oligomeric structure (Jedd and Chua 2000; Tenney et al. 2000; Soundararajan et al. 2004).

Our findings suggest that Woronin bodies are still present and functional in tested autophagy-defective strains. Microscopic analysis using SmHEX1 in  $\Delta$ Smnbr1 and  $\Delta$ Smatg8 mutants confirmed the presence of these organelles. In the Western blot several bands of DsRED-SmHEX1 suggested that different oligomers of the protein exist in the mutants and in wild type (Figure 33). Fluorescence microscopic analysis revealed that the DsRED-SmHEX1 reporter protein localizes to septal pores and Woronin bodies which plug septal pores after injury in wild type and the  $\Delta$ Smnbr1 mutant (Figure 33). Thus, selective degradation of Woronin bodies seems to be not affected in  $\Delta$ Smnbr1. Furthermore, it can be assumed that Woronin bodies and HEX1 protein are very stable and have a low turnover rate. Therefore, it will be difficult to establish assays for “Woroniphagy”.

#### **4.2.7 SmNBR1 is involved in selective degradation of the large ribosomal subunit**

The present study supports the notion that ribosomal subunits are not only degraded by bulk autophagy, but also selective autophagic ribosomal turnover takes place in the ascomycete *S. macrospora*. It is known that ribosomes constitute half of the cell’s protein mass (Warner 1999) and consequently, represent a major source of amino acids during times of nutrient deprivation and adjustment to stress-inducing conditions. In addition, ribosomal degradation during starvation might be important for the rapid and simultaneous downregulation of protein translation, a process that consumes large amounts of energy and amino acids. Mature ribosomes are randomly sequestered into autophagosomes and degraded in the vacuole during non-selective autophagy. On the other hand, reports in *S. cerevisiae* suggest that under specific conditions a cargo receptor binds to ribosomal subunits followed by their exclusive enwrapping into double-membrane vesicles and their subsequent selective degradation via ribophagy (Kraft et al. 2008).

Observations in *S. cerevisiae* have revealed that the large 60S ribosomal subunits are more rapidly degraded compared to other cytoplasmic components, supporting the idea of a selective degradation process. The involvement of autophagy in this process was demonstrated by uncovering that the transport of ribosomes to the vacuole relies on core autophagy components such as Atg1 and Atg7 (Kraft et al. 2008). A genetic screen in yeast designed to isolate mutant strains with a defect in ribosome turnover revealed that the ubiquitin protease Ubp3 and its cofactor Bre5 are required for this selective type of autophagy, however, not for bulk autophagy (Figure 40A). Under nutrient-rich conditions, the ubiquitin ligase Ltn1 ubiquitinates the 60S

ribosomal subunit protein Rpl25 and protects it from degradation by autophagy, whereas under starvation conditions deubiquitination of Rpl25 by the deubiquitinase complex Ubp3/Bre5 induces degradation of the large 60S ribosomal subunit. It was suggested that deubiquitinated Rpl25 is the target of a ribophagy cargo receptor (Kraft et al. 2008; Ossareh-Nazari et al. 2014). However, the selective receptor for ribosome-autophagosome assembly was not yet been identified in *S. cerevisiae*.

**Figure 40: Hypothetical model for the ribophagy of the large ribosomal subunit in *S. cerevisiae* and *S. macrospora*.**

(A) In *S. cerevisiae*, under nutrient-rich conditions the E3 ligase Ltn1 ubiquitinates Rpl25 from the large 60S ribosomal subunit. In contrast, under starvation conditions the level of Ltn1 decreases and the Ubp3/Bre5 deubiquitinase complex acts in the deubiquitination of Rpl25. Rpl25 is targeted by a still unknown receptor for selective autophagy. (B) It is hypothesized that in *S. macrospora* SmNBR1 (Nbr1) binds selectively to a protein of the large ribosomal subunit or another yet unknown protein to bridge the 60S subunit including SmRPL25 (Rpl25) to the PAS. The autophagosome encloses the cargo, which is in turn delivered to the vacuole to form the autophagic body. The whole content is degraded into their constitutive nutrients and released into the cytosol for reuse. 60S, large ribosomal subunit; Ub, ubiquitin; PAS, phagophore assembly site.

In *S. macrospora*, the deletion of *Smnbr1* results in a defect in the turnover of the large ribosomal subunit protein SmRPL25-EGFP shown by quantitative Western-blot experiments and fluorescence localization studies (Figure 34). Importantly, SmATG8 is normally degraded by autophagy in this deletion strain (Figure 37). The transport of SmRPL25-EGFP to the vacuole relies on the core autophagy protein SmATG8 because SmRPL25-EGFP is not degraded in a  $\Delta$ Smatg8 strain. Additionally, the interaction of SmNBR1 and the 60S ribosomal subunit protein SmRPL25 could be verified *in vivo* by immunoprecipitation (Figure 38). However, a yeast-two hybrid analysis revealed that SmRPL25 is no direct interaction partner of SmNBR1 (Supplement 8).

The analysis of the small ribosomal subunit protein SmRPS19 shows the same localization as SmRPL25 in fluorescence microscopy. In the wild type the EGFP-tagged SmRPS19 is degraded in the vacuole whereas a stabilization of SmRPS19-EGFP is visible in  $\Delta$ Smnbr1 and

the autophagy-defective mutant  $\Delta$ Smatg8 (Figure 35A,C). Surprisingly, the quantitative Western-blot analysis of SmRPS19-EGFP revealed no significant differences in stability when the wild type and the  $\Delta$ Smnbr1 strain were compared under rich and starvation conditions (Figure 35B,D). However, it has to be considered that the time point of fluorescence microscopic analysis differs from the time point of the Western-blot quantification. Due to technical reasons for microscopic localization studies, strains were analyzed after 18-72 h of growth whereas proteins for the Western-blot analysis were sampled after 3-6 days of growth. Therefore, it might be that after a certain time of growth stability of ribosomal proteins reach a steady state level that do not allow to detect further differences in stability. Therefore, it is not clear that the degradation of SmRPS19 is really independent of the selective receptor SmNBR1. Nevertheless, similar to SmRPL25, SmRPS19-EGFP was stabilized in the autophagy-defective mutant  $\Delta$ Smatg8, which indicates that also the small ribosomal subunit was degraded in an autophagy-dependent manner.

In the GFP-Trap analysis using SmNBR1 as bait protein many ribosomal associated proteins were identified by LC/MS analysis as putative interaction partners (Table 7). Astonishingly, the interaction partner of SmNBR1 identified with the highest significance was the small ribosomal subunit protein SmRPS27. Additionally, SmRPS21 and one large ribosomal subunit protein SmRPL28 were identified among the eight best hits. Moreover, SmRPS26 was identified as the 16<sup>th</sup> best hit (data not shown).

A BLASTP search revealed that SmRPL28 is not encoded in *S. cerevisiae* and other yeasts. The RPL28 of *S. macrospora* is a homolog of the human and *Drosophila melanogaster* L28e protein, which is lacking in yeast (Anger et al. 2013). Another interesting candidate among the eight best hits is the ribosome-associated protein SmSTM1 which has been shown to stabilize ribosomes during starvation conditions (Van Dyke et al. 2006; Ben-Shem et al. 2011; Jenner et al. 2012). SMAC\_04779 (fatty acid degradation enzyme), SMAC\_02849 (amino-acid biosynthesis) and SMAC\_00402 (pyrimidine metabolism) among the best eight hits are predicted to have enzymatic activities in general metabolic processes. BLASTP searches at UniProt (<http://www.uniprot.org/blast/uniprot/>) revealed that these metabolic proteins are conserved among ascomycetes.

Figure 41 represents the crystal structure of the 80S ribosome of human with highlighted ribosomal subunit proteins identified in GFP-Trap analysis, including RPS21, 26, 27 and RPL28, as well as the proteins used for stability analysis, RPS19 and RPL25. In this model the small 40S ribosomal subunit proteins identified in GFP-Trap analysis (RPS21, 26, 27) localize on a different position as the RPS19 protein which was tested for SmNBR1-dependent

degradation. Also RPL25, which was assayed in the ribophagy analysis, is localized apart from RPL28 in the crystal structure. Therefore, it is not surprising that RPL25 was not identified as a direct interaction partner of SmNBR1 in the yeast-two hybrid analysis. The ribosomal proteins and the ribosomal-associated protein STM1 identified in the GFP-Trap analysis are therefore excellent candidates to test SmNBR1-dependent ribophagy in the future.

**Figure 41: Crystal structure of the 80S human ribosome and ribosomal RNA (Anger et al. 2013).**

(A) Molecular model of the 80S human ribosome consists of the 60S subunit (dark grey) and the 40S subunit (light grey) in cartoon representation (PDB ID: 4V6X). Ribosomal proteins are coloured individually. The large 60S ribosomal subunit proteins RPL25 (known in human as L23A (Ban et al. 2014)) is labeled in orange and RPL28 is labeled in red. The small 40S ribosomal subunit proteins RPS27 is labeled in cyan, RPS26 in purple, RPS21 in light blue and RPS19 is labeled in dark blue. (B) 80S human ribosome with rRNA shown in white as cartoon representation (PDB ID: 3J3D, 3J3F).

The results demonstrate that functional SmNBR1 is required to promote the selective degradation of mature 60S ribosomal subunits. It can be speculated that under starvation conditions SmNBR1 acts as cargo receptor to bind to the 60S ribosomal subunit and recruits surplus ribosomal subunits to autophagosomes for their degradation in the vacuole. The direct target of SmNBR1 is so far unknown. Ribosomal proteins identified in the GFP-Trap analysis might be the targets of SmNBR1 or alternatively a yet unknown protein. It is rather unlikely that ubiquitin or deubiquitination are involved in this process (Figure 40B) since ubiquitin was not identified as SmNBR1-interacting protein. Further, SmNBR1 does not exhibit an obvious UBA domain and  $\Delta$ Smnbr1 showed no accumulation of ubiquitinated proteins.

In summary, the findings of this thesis imply that SmNBR1 is a homolog of the mammalian autophagy cargo receptor NBR1. Moreover, the results reveal that the selective recognition and binding of excessive, damaged or non-functional ribosomes as well as peroxisomes are crucial for vegetative growth under stress conditions and for sexual development in *S. macrospora*.

**Supplement 1: Multiple-sequence alignment of ATG5 orthologs from *Homo sapiens*, *Saccharomyces cerevisiae* and *Sordaria macrospora*.**

ClustalX alignment was created using the following sequences: Smac, *S. macrospora* (XP\_003347373.1), Scer, *S. cerevisiae* (DAA11286.1) and Hsap, *H. sapiens* (Q9HIY0.2). Amino acids which are conserved in all proteins, are shaded in black; residues conserved in two of three sequences are shaded in grey. The conserved lysine residue (Smac Lys 218, Scer Lys 149, Hsap Lys 130) which forms the conjugate with the C-terminal SmATG12 glycine residue is marked in red.

**Supplement 3: Alignment of single domains of NBR1 homologs in different species.**

(A) Alignment of the conserved region at the C-terminus of ascomycetes and basidiomycetes. Asterisks label the three conserved serine (S) residues in ascomycetes. Ascomycetes: Sm, *Sordaria macrospora* (XP\_003346367); Nc, *Neurospora crassa* (XP\_011394647); Nt, *Neurospora tetrasperma* (XP\_009847604); Pa, *Podospora anserina* (XP\_001912058); Mt, *Myceliophthora thermophila* (MYCTH\_2302632); Ct, *Chaetomium thermophilum* (XP\_006696593); Man, *Metarhizium anisopliae* (EFY98453); Mac, *Metarhizium acridum* (EFY92904); Fo, *Fusarium oxysporum* (EMT63555); Af, *Aspergillus fumigatus* (XP\_755022); Ao, *Aspergillus oryzae* (XP\_001824430); An, *Aspergillus nidulans* (XP\_661032); Pc, *Penicillium chrysogenum* (XP\_002563338). Basidiomycetes: Sc, *Schizophyllum commune* (XP\_003038660); Cc, *Coprinopsis cinerea* (XP\_001829200). (B) Alignment of the LIR motif at the C-terminal part with the same species as in (A). Asterisks label the conserved (W/Y/F<sub>0</sub>) and (L/I/V<sub>3</sub>) side. Amino acids, which are conserved in all proteins, are shaded in black; residues conserved in two of three sequences are shaded in grey.

**Supplement 4: Heterologous protein production of HsNBR1-DsRED in  $\Delta$ Smnbr1::Hsnbr1-Dsred<sup>ect</sup> strains.** Expression of an *Hsnbr1-Dsred* fusion construct in  $\Delta$ Smnbr1 mutant was determined by Western blotting using a monoclonal anti-RFP antibody. Three representative transformants are shown. Wt and a strain expressing free DsRED (wt::RHN1<sup>ect</sup>) served as controls. The strains were grown for 3 d in BMM complex medium. The crude protein extracts analyzed were prepared from strains  $\Delta$ Smnbr1::Hsnbr1-Dsred<sup>ect</sup>, wt::RHN1<sup>ect</sup> and the untransformed wt strain.

**Supplement 5: Fluorescence localization of SmNBR1-EGFP in the complemented  $\Delta\text{Smn}br1$  strain.**

(A) Analysis of the strain  $\Delta\text{Smn}br1::\text{Smn}br1\text{-egfp}^{\text{ect}}$  carrying the plasmid pSmnbr1-egfp. SmNBR1-EGFP localizes to vacuoles and autophagosomes which are indicated by arrows. Vacuoles were stained with CMAC. (B) Localization of free EGFP in the  $\Delta\text{Smn}br1$  strain. DIC, differential interference contrast. Scale bars are indicated.

**Supplement 6: Quantitative Western experiment of vacuolar degradation of EGFP-SMATG8 under amino-acid starvation condition in different autophagy mutants.**

Expression of an EGFP-SmATG8 fusion construct in different autophagy mutants was determined by Western blotting using a monoclonal anti-EGFP antibody. The strains were grown for 3 d in BMM complex medium supplemented with 2.5 mM 3-AT. Wt and a strain expressing free EGFP served as controls and were grown for 3 d in BMM complex medium. The crude protein extracts analyzed were prepared from strains  $\Delta$ Smag8::egfp-Smatg8<sup>ect</sup>,  $\Delta$ Smag12::egfp-Smatg8<sup>ect</sup>,  $\Delta$ Smag4::egfp-Smatg8<sup>ect</sup>,  $\Delta$ Smnbr1::egfp-Smatg8<sup>ect</sup>, wt::1783-1<sup>ect</sup> and the untransformed wt strain. Ponceau staining served as loading control to check the protein levels. The program ImageJ was used to quantify the ratio between cleaved EGFP and the EGFP-SmATG8 fusion protein. The cleavage of EGFP in the complemented strain  $\Delta$ Smag8::egfp-Smatg8<sup>ect</sup> was set to 100 %. One of three independent experiments is shown. Error bars are indicated.

**Supplement 7: Localization studies of SmRPL25-EGFP and SmRPS19-EGFP.**

(A) Analysis of wt strain carrying the plasmid pSmrpl25-egfp after 24h growth on BMM medium. SmRPL25-EGFP localizes to the nucleus and cytoplasm. Nuclei were stained with DAPI. (B) Analysis of wt strain carrying the plasmid pSmrps19-egfp after 24h growth on BMM medium. SmRPS19-EGFP localizes to the nucleus and cytoplasm. Nuclei were stained with DAPI. (C) Analysis of wt strain carrying the plasmid pSmrps19-egfp and pSmnbr1-Dsred after 48h growth on BMM medium. Both proteins co-localize to the vacuoles. DAPI, 4',6-Diamidino-2-Phenylindole; DIC, differential interference contrast. Scale bars are indicated. Merged images are shown.

**Supplement 8: Yeast-two hybrid assay of SmRPL25 and SmRPS19 with the cargo receptor SmNBR1.**

Full-length cDNAs of *Smrpl25*, *Smrps19* and *Smnbr1* were used to generate Gal4-DNA binding (BD) and Gal4-activation domain (AD) plasmids. Yeast strains Y187 and AH109 were transformed and mated in different combinations. The mated yeast cells were grown on SD minimal medium -trp and -leu (SD-TL) for selection of the plasmids. SD medium lacking -trp, -leu, -ade (SD-TLA) was used for interaction studies. Each drop assay was performed in 10-fold serial dilutions ( $10^{-1}$ - $10^{-4}$ ). Here, the growth of the first dilution is shown. As a negative control (-), the query vectors pGADT7/pGBKT7, and for positive controls (+) the pAD-ranBPM/pBD-Smrpl25 or pBD-Smrps19 were used. RanBPM can be used as positive control because it is able interact with the Gal4-BD (Tucker et al. 2009).

## 7. Danksagung

Herzlichen Dank, liebe Frau Prof. Dr. Stefanie Pöggeler. Sie als meine Doktormutter haben immer ein offenes Ohr für meine Anliegen und Probleme gehabt und mir Mut verliehen, wenn es einmal nicht so gut gelaufen ist für mich. Ihr Interesse am Fortschreiten der Forschungsarbeit hat mir immer wieder neuen Anstoß gegeben, noch motivierter zu arbeiten. Ich danke Ihnen für die Möglichkeit meine Promotion in ihrer Arbeitsgruppe absolvieren zu können und das damit entgegengebrachte Vertrauen.

Ich danke Herrn Prof. Dr. Gerhard Braus und Prof. Dr. Michael Thumm, für die wissenschaftliche Betreuung sowie den hilfreichen Diskussionen und Ratschlägen als Mitglieder meines Thesis Committees.

Des Weiteren möchte ich mich bei Dr. Oliver Valerius für die Zusammenarbeit an einigen Projekten bedanken.

Mein außerordentlicher Dank gilt Dr. Britta Herzog, die mehrfache Durchsicht dieser Abhandlung, ihre kritischen Betrachtungen und ihre Anmerkungen haben zur Anfertigung und Vollendung meiner Dissertation bei getragen. Vor allem aber wegen ihrem moralischen Beistand und dem menschlichen Halt, gebührt ihr hier mein besonderer Dank. Sie ist nicht nur eine Kollegin sondern über die Zeit auch zu einer guten Freundin geworden.

Dankbar anerkennen will ich mich auch bei Gertrud Stahlhut, ihre immer freundliche und uneingeschränkte Bereitschaft mir ihr Laborwissen weiterzugeben, hat meine Leistungen im Labor gestärkt. Ihr danke ich für die ausgezeichnete und akribische Hilfe bei meinen Experimenten, aber auch für die privaten Gespräche und Ratschläge als „Labormutti“.

Ein ganz besonderer Dank geht an meine Mitdotorandin Eva Reschka, zusammen haben wir unser Masterstudium und unsere Promotion durchlebt mit allen Höhen und Tiefen.

Allen ehemaligen Mitarbeitern und Studenten die an meinem Projekt mit gearbeitet haben, gilt herzlicher Dank. Besonders erwähnen möchte ich Silvia Carrillo-Castellon die als Laborgehilfin ein sehr gutes Arbeiten ermöglicht hat.

## Danksagung

---

Allen meinen lieben Freunden danke ich für die Ausdauer, Ruhe und Geduld, womit sie mir stets zur Seite standen und mich immer wieder aufgemuntert haben. Ihr habt mich im richtigen Moment abgelenkt um wieder Kraft zu tanken und einen klaren Blick zu bekommen.

Eine herausragende Stellung in jeglicher Hinsicht nimmt meine Familie ein doch ganz besonders meine Eltern und mein Ehemann Sebastian. Ohne Ihren Beistand wäre diese Arbeit nicht zu dem Werk geworden, welches sie heute ist. Vielen Dank für eure Unterstützung über den gesamten Zeitraum der Promotion und des Studiums, gerade aber in der Endphase in der es viele stressige und erschöpfende Momente gab.

## 8. Curriculum vitae

Antonia Werner geb. Jakobshagen  
Georg-August University Göttingen  
Institute of Microbiology and Genetics  
Department of Genetics of Eukaryotic Microorganisms  
Grisebachstraße 8  
Göttingen, Germany  
E-mail: ajakobs1@gwdg.de

Date of birth: January 10<sup>th</sup> 1988

Place of birth: Leinefelde

Nationality: German

### Education

- 04/2013-present      PhD student in the GGNB program Microbiology and Biochemistry, Georg-August University Göttingen, Department of Genetics of Eukaryotic Microorganisms, Title of the thesis: “The interplay of SmNBR1 and SmATG8 in selective autophagy of the filamentous fungus *Sordaria macrospora*” Thesis Committee: Prof. Dr. Stefanie Pöggeler, Prof. Dr. Gerhard Braus, Prof. Dr. Michael Thumm
- 11/2012-03/2013      Scientific assistant, Georg-August University Göttingen, Department of Genetics eukaryotic Microorganisms
- 09/2012                Master thesis, Georg-August University Göttingen, Department of Genetics of Eukaryotic Microorganisms, Title of the thesis: “Functional analysis of the putative autophagy receptor SmNBR1 and the autophagic protein SmATG12 of the filamentous ascomycete *Sordaria macrospora*”
- 10/2010-09/2012      Master student in master program Molecular Biology, Georg-August University Göttingen
- 09/2010                Bachelor thesis, Georg-August University Göttingen, Department of Molecular Microbiology and Genetics, Title of the thesis: “Characterization of the Gcn4p Hac1p-interplay in the yeast *Saccharomyces cerevisiae*”

- 10/2007-09/2010 Bachelor student in Molekulare Biowissenschaften, Georg-August University Göttingen
- 08/2004-07/2007 Berufliches Gymnasium Mühlhausen (Abitur)

### **Talks**

- 10/2015 VAAM 2015 Berlin  
“The selective autophagy cargo receptor SmNBR1 in the ascomycete *Sordaria macrospora*”
- 07/2013 Retreat of the GGNB program “Microbiology and Biochemistry”  
“The selective autophagy cargo receptor SmNBR1”

### **Posters**

- 12/2016 4<sup>th</sup> GGNB Science Day at the Georg-August University Göttingen, Germany  
“The selective autophagy cargo receptor SmNBR1 in the ascomycete *Sordaria macrospora*”
- 03/2015 28<sup>th</sup> Fungal Genetics Conference in Asilomar, Kalifornien, USA  
“The selective autophagy cargo receptor SmNBR1 in the ascomycete *Sordaria macrospora*“
- 10/2014 VAAM 2014 Dresden, Germany  
“Selective autophagy in the filamentous fungus *Sordaria macrospora*”
