A mi madre

I. ACKNOWLEDGEMENTS

This work wouldn't be possible without the help from many people. Therefore, I would like to express my gratitude to all that contributed to the present dissertation:

To **Dr. Stefan Nessler** for the insightful comments on this thesis, the lab training at the bench, the tireless work and input to the project and the relentless supervision.

To **Prof. Dr. Christine Stadelmann** for all the support during the last four years.

To **Prof. Dr. Wolfgang Brück** for letting me join the Neuropathology department and for all valuable comments during my progress reports and committee meetings.

To **Prof. Dr. Klaus-Armin Nave**, **Prof. Dr. Alexander Flügel** and **Prof. Dr. Holger Reichardt** for being in my thesis advisory meetings and for all suggestions and discussions that enriched the project. I'm also thankful to **Prof. Hannelore Ehrenreich** and to **Prof. Fred Wouters** for being part of the extended committee board.

To the excellent team of technical assistants: **Brigitte**, **Jasmin**, **Heidi**, **Angela**, **Elke**, **Uta** and **Olga**. Special thanks to **Katja** for her great help in immunohistochemistry and performing the genotypings of the different transgenic mouse lines.

To **Jana** and **Anne** for their helpful feedback on this manuscript and to my colleagues: **Claudia**, **Franzi**, **Nielsen**, **Patrick**, **Alonso**, **Susi**, **Nasrin**, **Carolin**, **Darius**, **Sandra**, **Silke**, **Jasmin** and **Sebastian** for their scientific advice.

To the **Neuroscience Program IMPRS** and the deeply committed coordination team led by **Prof. Dr. Michael Hörner** and **Sandra Drube** for guidance provided since I came to Germany in 2012. Many thanks for always keeping an open door for me and for letting this whole adventure begin.

To **Heidi** and **Cynthia** for the administrative help and to **Bernd** for the IT support and for lending me his quiet office to write my dissertation.

Last but not least to my **family** and **friends** which always supported me and deserve a special mention in Spanish, my mother language:

AGRADECIMIENTOS

Antes que nada, le dedico esta tesis a **mi madre**, por motivarme a luchar por alcanzar mis sueños, aún si eso significa vivir a más de 10 mil kilómetros de distancia de mis seres queridos. Por enseñarme que lo importante es el viaje no el destino y por hacerme sentir tan querida en cada etapa de mi vida.

A mis **abuelos Irma y Alfonso** por ser un ejemplo de honradez, trabajo y esfuerzo.

A mi life-couch **Poncho** por nunca dejar de creer en mí.

A **Beto** por todo su apoyo y por regalarme la tranquilidad de que he dejado a mi madre bien acompañada.

A mi **tía Rebeca** por ser ejemplo e inspiración tras la tremenda batalla que le ha dado a la neuromielitis óptica.

A mi **tía Blanquita** que con sus cartas y detalles siempre está al pendiente de mí.

A mis primos **Rebeca, Julián, Chuchito** y **Carolina** por recordarme, cada uno a su manera, el legado de superación y entrega que nos dejaron nuestros padres.

A toda mi **familia** y **amigos en el DF** y **Göttingen** porque sin su ayuda y apoyo no estaría aquí.

¡A todos mil gracias!

II. ABSTRACT

The aryl hydrocarbon receptor (AhR) is a ligand activated transcription factor highly expressed within the immune and nervous system. Structurally diverse endogenous and synthetic ligands activate AhR, including dietary, microbial and physiological compounds, suggesting a potential crosstalk between AhR's signaling, diet, microbiome, and immune system. The aim of the present thesis was to evaluate if endogenous AhR ligands influence the development of spontaneous CNS autoimmunity. For this purpose, double transgenic opticospinal (OSE) mice carrying myelin oligodendrocyte glycoprotein (MOG) specific T and B cell receptors were generated with or without AhR competent dendritic cells (DC), CD4⁺ T cells, regulatory T cells (T_{regs}) or astrocytes. The spontaneous EAE incidence significantly increased in OSE animals with AhR deleted in DC (OSE AhR^{ΔDC}), but not in OSE mice devoid of AhR in CD4⁺ T cells, T_{regs} or astrocytes. OSE AhR^{ΔDC} CX3CR1^{EGFP/+} reporter mice were generated in order to assess the antigen presenting cells (APCs) of the lamina propria (LP), where MOG specific CD4⁺ T cells are likely activated in the OSE mouse model. AhR deficiency of DC increased the frequency of CX3CR1^{int} DC and correspondingly decreased the frequency of CX3CR1⁻ DC. The presence of CX3CR1^{int} DC and CX3CR1⁻ DC was confirmed by immunohistochemistry in the LP of CD11c^{tdTomato} CX3CR1^{eGFP} reporter mice. CX3CR1^{int} DC showed higher MHCII expression than CX3CR1⁻ DC. Thus, might be better equipped to initiate the activation of MOG specific naïve T cells. Compared to OSE AhR^{fl/fl} control littermates, OSE AhR^{ΔDC} mice showed higher frequencies of IFN γ ⁺ transgenic CD4⁺ T cells in the LP and increased MOG specific IgG2a antibodies in the sera. Furthermore, supplementing a single AhR ligand to the diet of OSE mice, spontaneous EAE was almost completely abolished. Finally, it was aimed to define the relevant cellular players mediating the therapeutic efficacy of the presumed and clinically relevant AhR agonist, Laquinimod, against EAE. Laquinimod significantly protected AhR^{ΔDC}, AhR^{ΔCD4}, AhR^{ΔTreg} and AhR^{ΔAstro} mice, but its protective effect was less sustained in AhR^{ΔDC} mice. In summary, this work provides evidence showing that the physiological concentrations of AhR ligands modulate CNS autoimmunity via AhR competent DC.

1. INTRODUCTION

1.1 Multiple sclerosis

Multiple sclerosis (MS) is a currently incurable chronic inflammatory and demyelinating disease of the central nervous system (CNS). It is considered autoimmune in nature and its cause remains unknown. MS is characterized by lymphocytic and monocyte/macrophage infiltrates wreaking havoc to the myelin sheaths and oligodendrocytes¹. Inflammatory demyelination is associated with axonal and neuronal pathology, which are considered the major pathological determinants of irreversible neurological disability.

Around 80% of MS patients start with a relapsing remitting (RRMS) clinical course, which is characterized by episodes of neurological dysfunction followed by recovery periods. Patients typically present initially vision problems, numbness and or muscle weakness². With time, 65% of the RRMS patients enter a secondary progressive (SPMS) stage of the disease, characterized by a gradual physical decline with no noticeable remissions. A primary progressive (PPMS) disease course can be found in 15-20% of the MS cases and usually starts in male patients after the age of 40³.

1.1.1 MS Epidemiology

MS is the most frequent inflammatory demyelinating disorder with a prevalence that varies considerably between regions with high rates in North America and Europe (less than 100 per 100 000 inhabitants) and low rates in eastern Asia and sub-Saharan Africa (2 per 100 000). In addition, MS is considered the most frequent non-traumatic disorder leading to neurological disability in young adults⁴.

As the most prevalent inflammatory disorder of the CNS, MS affects more than 2 million people worldwide⁵. The highest prevalence occurs in Europe where more than half of the diagnosed MS patients live^{6,7}. Just in Germany, there are an estimated 100 to 140 thousand MS patients, which are generally diagnosed around the age of 35 years⁸.

Similar to other autoimmune disorders, MS is more prevalent in women than men; suggesting a role of sexual hormones, as well as gender differences in genes, development and function of the immune and nervous system^{3,9}. The female-male ratio has significantly increased in the last decades (2.3-3.5:1). This significant increase of MS in women could be caused by environmental changes and nutrition¹⁰.

1.1.2 MS Etiology

Since Jean-Martin Charcot first described MS in 1868, its etiology has been extensively studied in order to design possible therapies that allow us to treat and ultimately cure the disease¹¹. However, MS remains incurable up to now and the precise factors initiating the development of the disease are unclear.

Like most autoimmune diseases, MS is considered a multifactorial disorder with genetic and environmental risk factors. Furthermore sex, age, race, cultural and socio-economic conditions might enter the intricate interaction of elements triggering the disease¹². MS complexity probably resides in the fact that none of these factors is essential or sufficient to trigger or at least, to predict the disease.

1.1.2.1 Genetic risk factors

Recent studies conclude that genetic variation might be accountable for about 50% of the individual differences in MS susceptibility^{13,14}. Different population-based studies have shown MS concordance rates for monozygotic twins (~25%), dizygotic twins (~5.4%) and siblings (~3%)¹⁵⁻²⁰.

Having a first degree relative with MS increases the risk up to 2 – 4%, which is already 20 – 40 times higher than the 0.1% prevalence in the general population²¹. The likelihood to develop MS increases around 5– fold when both parents have the disease (12.2%) compared to one parent affected (2.5%)²²⁻²⁷.

The first identified MS genetic risk locus was the major histocompatibility complex (MHC) on chromosome 6p21, specifically the human leukocyte antigen HLA-DR2 or

DRB1*1501-DQB1*0602 extended haplotype. This extremely polymorphic region has shown the most consistent association with MS by genome wide association studies (GWAS) and case-control studies.

Carrying one copy of the HLA-DRB1*1501 haplotype increases the risk to develop MS 2-3 fold, while carrying two copies elevates the risk by 6-fold^{15,28-30}. Interestingly, other HLA alleles have been confirmed as MS protective factors including HLA-C554, HLA-DRB1*11, HLA A*02 and HLA B*4402^{3,31}.

At present, more than 50 non-HLA genetic risk factors for MS have been discovered and most belong to genes affecting the immune response. Namely, interleukin 2 receptor α chain (IL2RA), interleukin 7 receptor α chain (IL7RA), CD58, C-Type Lectin Domain Containing 16A (CLEC16A), nuclear receptor NR1.H3 and enzyme 1 α -hydroxylase CYP27B1 (involved in vitamin D metabolism) are additional susceptibility genes for MS³²⁻³⁶.

1.1.2.2 Environmental risk factors

Since Charcot detected the variability in the incidence of MS around the world in 1877, plenty of evidence has been gathered regarding the environmental factors that could make an individual more susceptible to develop MS³⁷. More than two decades ago, Kurtzke defined prevalence regions due to the geographically asymmetric distribution of MS^{38,39}.

Nowadays, latitudinal gradients have been identified in Europe, North America, Australia and Asia concerning MS geoepidemiology^{6,40-46}. The greater number of MS cases in higher latitudes compared to lower ones supports the importance of environmental factors modulating MS onset. For instance, vitamin D assimilation, exposure to ultraviolet (UV) radiation, smoking and pathogens have been related to the risk of developing MS⁴⁷.

1.1.2.3 Vitamin D

Due to the inverse correlation between MS prevalence and sunlight exposure and given the fact that UV light is essential for vitamin D₃ (cholecalciferol) synthesis in the skin, vitamin D deficiency has been long considered a modifiable risk factor for MS⁴⁸⁻⁵⁰. Vitamin D and solar

radiation have been shown to play differential effects on the immune cells located in the skin^{51,52}. The vitamin D receptor (VDR) is expressed in most cells of the human body, is involved in numerous cell processes and protects against autoimmune diseases^{36,53–56}.

Even though the most important source of vitamin D is induced by sun exposure in the skin, this fat soluble steroid can be also obtained from the diet and supplements⁵⁷. The precise role of the vitamin D, as well as the diet's impact on MS susceptibility have not been fully elucidated, however both have been suggested to play a role in the disease since the early 50's^{58,59}.

1.1.2.4 Diet

Diet habits have been long associated to MS, particularly the fat^{60,61}, salt^{62–64} and fiber consumption^{65–67}. A large longitudinal study from 2012 reported that the Mediterranean diet prevents white matter lesions and cognitive decline by protecting small vessels in the brain⁶⁸. This type of diet has been associated with reduced MS risk because it involves a high intake of fruits, vegetables, fish, whole grains, legumes and nuts^{69–71}.

Although there is no particular diet recommended for MS patients, following a healthy nutritional scheme has been positively associated with the composition of gut bacteria and the immune system homeostasis^{67,72–78}. Besides nutritional status, obesity^{79–81}, malnutrition⁸² and related disorders, such as dyslipidemia⁸³ and hypertension⁸⁴ have been connected with MS.

1.1.2.5 Viral infections

Among the environmental factors, viral infections caused by herpesviruses, namely the human herpesvirus 6 (HHV-6) and Epstein-Barr virus (EBV), have been associated to MS pathogenesis. The former is linked to MS due to a greater appearance of HHV-6 in MS lesions compared to MS normal appearing white matter possibly indicating that HHV-6 can be reactivated during MS relapses^{85,86}.

EBV is implicated in the pathogenesis of MS due to universal seropositivity and high anti-EBV antibody levels compared to age matched controls^{85,87–89}. Furthermore, defective

control of EBV infection by cytotoxic CD8⁺ T cells might predispose to MS by allowing EBV-infected autoreactive B cells to accumulate in the central nervous system^{87,90}.

Another hypothesis postulates that after viral infection, activated T cells recognize CNS antigens due to molecular similarity or mimicry. Nevertheless, this hypothesis extends to T cells primed in the periphery by any other infectious antigen or superantigen^{91,92}.

Despite the fact no single environmental factor has been proven to cause MS, all mentioned environmental factors are able to directly or indirectly modulate immune responses and to influence protein and gene expression possibly affecting the likelihood to develop MS.

1.2 Experimental Autoimmune Encephalomyelitis

Experimental autoimmune encephalomyelitis (EAE) is the most commonly used animal model for MS. It can be induced by active immunization with myelin proteins/peptides emulgated in complete Freund's adjuvant (CFA) or by the adoptive transfer of myelin specific T cells into syngenic recipients^{92,93}.

Active EAE is achieved by immunization with myelin peptides depending on the mouse strain⁹⁴. For example, the proteolipid peptide (PLP) is used for SJL/J mice immunization⁹⁵, myelin oligodendrocyte glycoprotein (MOG) for C57BL/6 mice^{96,97} and myelin basic protein (MBP) for B10.PL mice⁹⁸.

In order to increase disease incidence, pertussis toxin is often administered at the time of the immunological challenge and two days later⁹⁹. On the other hand, passive EAE is induced by adoptive transfer of encephalitogenic T cells, which can be *in vitro* manipulated before being inoculated to the recipients. The autoreactive T cells could be also labeled to follow their localization and interactions with other cells¹⁰⁰.

Alternatively, spontaneous EAE can be observed in myelin specific T cell receptor transgenic mice. The frequency of spontaneous EAE can be significantly increased in animal strains less prone to EAE development such as C57BL/6 mice by generating MOG specific T and B cell receptor transgenic mice such as the opticospinal (OSE) mice. In contrast to single

transgenic animals, around 50% of the OSE mice develop spontaneous EAE in the first 10 weeks of age depending on the housing conditions^{101,102}.

Environmental factors vary depending on the animal facility and shape the microbiota composition, propensity to develop infections and immune responses. It is thought that external stimuli could trigger the autoimmune conversion of innocuous progenitors to pathogenic immune cells, leading to the combined attack of pathogenic T and B cells that potentially prompt spontaneous EAE development in the OSE mice¹⁰³.

The EAE model is considered a CD4⁺ or T helper (Th) cell mediated autoimmune disease that resembles MS features. For instance, CD4⁺ T cell and mononuclear cell infiltration with subsequent demyelination and clinical signs. CD4⁺ Th1 and Th17 cells are primed outside the CNS before crossing the blood brain barrier (BBB). Besides microglia activation and other inflammation mediators' attraction, IFN γ production by Th1 cells and IL17 by Th17 cells causes damage in the myelin covering the axons⁹².

Activation of MOG specific T cells in the gut-associated lymphatic tissue (GALT) is necessary for spontaneous EAE development in the relapsing remitting (RR) mice (SJL/J strain). According to Berer and colleagues¹⁰³ the commensal microbiota could provide innate immune signals or peptides that share similarities with MOG epitopes. Their observations in germ free (GF) mice demonstrated full protection through life against spontaneous EAE in the RR mice, supporting a central role of commensal microbiota shaping CD4⁺ T cell priming at the GALT.

In general, no animal model recapitulates all features and underlying mechanisms of any human disorder. However, the EAE experimental model has been widely used to identify therapeutic targets and molecular pathways relevant in MS pathophysiology¹⁰⁴.

1.3 Gut immune system

The gastrointestinal tract is the largest mucosal surface that separates the organism from the external environment. It comprises trillions of microorganisms termed the gut microbiome,

which have co-evolved with the host over millennia in a symbiotic relationship¹⁰⁵. The microbiota composition differs between individuals and performs essential functions to maintain the gut homeostasis, metabolism and immune system¹⁰⁶.

The microbial community contains between 1000 to 1500 species depending on environmental and genetic factors. Most of them are *Bacteroides* and *Firmicutes* (92%), that offer different metabolic benefits to the host and vice versa¹⁰⁷. For instance, the host provides a nutritive milieu and a suitable niche for colonization, whereas the gut microbiota contributes to the assimilation of nutrients, development of the epithelium and immune system, as well as modulation of innate and adaptive immune responses, among many others¹⁰⁸.

The intestinal wall is covered by finger-like protrusions called villi, whose major function is nutrient absorption and transport through its network of blood vessels. Nevertheless, these structures and the underlying tissues are also hosting the largest population of immune cells in mammals. The gut immune system coordinates a delicate balance directing immune responses against invading pathogens and providing tolerance to harmless microbes and food to avoid autoimmunity¹⁰⁹.

The gut mucosa is formed by a single layer epithelium and the connective tissue beneath, which is known as the lamina propria (LP). The epithelial cells or enterocytes line up the lumen of the intestines and together with the overlying mucus are the first point of contact with food and microbes. Enterocytes are intercalated by intraepithelial lymphocytes (IEL), with about one lymphocyte for every four to nine epithelial cells¹¹⁰.

IEL comprise roughly equal numbers of $\alpha\beta$ and $\gamma\delta$ T cells. They are a very heterogeneous group that includes: natural IEL, activated during development in the thymus in the presence of self-antigens and induced IEL, activated post-thymically in response to peripheral antigens. Both express activation markers such as CD69⁺ and CD44⁺¹¹¹.

Natural IEL are either CD8 $\alpha\alpha$ ⁺ or CD8 $\alpha\alpha$ ⁻ T cells that express $\gamma\delta$ or $\alpha\beta$ TCR but do not express CD4⁺ or CD8 $\alpha\beta$ ⁺ (CD8⁻ CD4⁻ double negative cells), whereas induced IELs arise from

conventional $\alpha\beta$ TCR CD4⁺ or CD8 $\alpha\beta$ ⁺ T cells. The natural IEL are the dominant T cell population in unchallenged mice. These cells enter the small intestine directly after maturation^{110–112}.

Secondary lymphoid structures are scattered along the gut mucosa and embedded in the LP forming the gut associated lymphoid tissue (GALT). Most of the GALT encloses dispersed leukocytes in diffuse masses under the gut epithelium. In some cases, leukocytes are arranged in more organized structures such as the Peyer's patches (PP). These dome-like organs are surrounded by a follicle-associated epithelium containing B cell follicles with germinal centers and interfollicular T cell areas¹¹³.

PP are considered gut immune sensors because of their ability to transport luminal antigens and bacteria through specialized phagocytic M (microfold) cells¹¹⁴. The matrix of the PP comprises T cells and the three major APCs types: macrophages, B cells and DC, increasing the probability of antigen uptake right after its release by M cells. Another mechanism of luminal sampling is executed by DC in the PP and LP, which extend their processes across the epithelial layer into the gut lumen. Once a DC has engulfed a bacterial antigen, it will then migrate through the lymphatic circulation to the closest mesenteric lymph node to present its antigenic cargo⁷⁰.

Pattern recognition receptors (PRR) activate DC and define the type of cytokines that they produce. These cytokines will then modulate the differentiation of naïve T cells into proinflammatory or regulatory lineages. Most intestinal CD4⁺ T cells are located in the LP. Even though they are activated by DC via antigen recognition in the context of MHCII, specific microbial stimulus can activate diverse differentiation programs characterized by particular transcription factors: Th1 (T-bet), Th2 (Gata-3), Th17 (Roryt) or T_{regs} (FoxP3)^{108,115,116}.

Proinflammatory stimuli can be exerted by different pathogens. For example, *Bacteroides fragilis* has been shown to induce T cell differentiation into Th1 cells that secrete IFN γ ¹¹⁷. Extracellular parasites promote a Th2 response with IL4, IL5 and IL13 secretion. Certain extracellular pathogens, such as segmented filamentous bacteria (SFB), stimulate

Th17 differentiation leading to IL17, IL17F and IL22 production^{118,119}. Conversely, it was shown that colonization with *Clostridium spp.* of the large intestine favors T_{regs} differentiation, which maintains a tolerogenic state by producing IL10, IL35 and TGFβ^{120,121}.

1.4 The aryl hydrocarbon receptor

One putative MS therapeutic target is the aryl hydrocarbon receptor (AhR), which is a ligand activated transcription factor widely expressed in the immune and nervous system. Despite the fact it is best known for mediating the toxic effects of chemical pollutants its evolutionary conservation suggests that binding toxins might not be its primary function. As part of the basic helix-loop-helix/Per-Arnt-Sim (PAS) homology superfamily, the AhR is a promiscuous receptor that can be activated by structurally diverse agonists found in the environment or endogenously produced^{122,123}.

1.4.1 AhR is ubiquitously distributed

Consistent with its role as environmental sensor, AhR is expressed in the liver and barrier tissues, such as gut, skin and lungs^{124,125}. Within the nervous system it is found in neurons and glia, showing particularly high levels in astrocytes^{126,127}. In the immune system, it is expressed in hematopoietic, innate, B and T cells¹²⁸.

High AhR expression has been reported in plasma cells, Th17, γδ T cells, innate lymphoid cells type 3 (ILC3), monocytes, macrophages, mast cells, dendritic cells (DC) and Langerhans cells^{76,129–135}. In contrast, AhR expression is significantly weak in the kidneys, secretory glands, muscle and stromal cells^{123,124}.

1.4.2 AhR endogenous and exogenous ligands

The AhR has been extensively studied in the toxicology field for its role during the biotransformation of different environmental pollutants. For example, the 2,3,7,8-tetrachloro-dibenzo-p-dioxin (TCDD) is the best known AhR xenobiotic ligand. However, a vast diversity of AhR ligands have been identified, including not only environmental toxins, but also dietary (obtained from vegetables, fruits and teas), commensal microflora and physiological

compounds. Some of the reported physiological AhR ligands are 6-formylindolo[3,2-b]carbazole (FICZ), kynurenine and indoles^{136–139}.

1.4.3 AhR signaling pathway

As an inactive protein, the AhR is located in the cytoplasm binding actin filaments and forming a multiprotein complex with the heat shock protein 90 (HSP 90), AhR-interacting protein (AIP), c-SRC protein kinase and the cochaperone p23. Upon ligand binding, the AhR undergoes a conformational change that allows it to bind importin β , to translocate into the nucleus and to release the complex^{123,136}.

In the active form, the AhR heterodimerizes with its interaction partner, AhR nuclear translocator (ARNT) and binds genomic regions containing the dioxin response element (DRE) motif. Hence, AhR induces the transcription of certain target genes, for example, AhR repressor (AhRR), indoleamine 2,3-dioxygenase 1 (IDO1), and enzymes corresponding to the cytochrome P450 (CYP) family, such as CYP1A1, CYP1A2 and CYP1B1^{137,140,141}.

1.4.4 AhR function

The AhR is considered a key regulator of gene expression networks underlying homeostasis, developmental processes, physiological and immune responses. Exerting its effect in a wide range of tissues, the AhR expression is tightly regulated and its functions are cell specific and diverse¹²⁸.

Depending on the ligand, AhR stimulation can activate different pathways producing different effects in the EAE model. For example, it can strongly influence the development of proinflammatory Th17 or anti-inflammatory regulatory T cells (T_{regs})¹⁴², maintain gut epithelial barrier integrity^{69,125} and modulate NK cell activation, innate lymphocyte cell (ILC) homeostasis and IL22 production^{72,143,144}. At large, activation of the AhR pathway can modulate CNS inflammation integrating immunological, metabolic and environmental stimuli^{126,145}.

1.4.5 AhR knock out animals

In order to elucidate AhR functions and to provide a sensible animal model for this environmental sensor, three AhR knock out (KO) strains have been developed. During the 90's, independent groups from Spain, Japan and the USA generated separately AhR KO mice by gene targeting of exons 1 and 2 of the AhR locus. Different strategies were used to disable the murine AhR locus *in vivo* producing mice yielding some, though minor, dissimilarities in their phenotypes¹³⁶.

The group of Prof. Frank Gonzalez inactivated the AhR gene by replacing the exon 1 containing DNA binding sites with a neomycin resistance gene¹⁴⁶. 40-50% of these mice die postnatally. Furthermore, they often have lower splenocyte numbers, eosinophilia and lymphocyte infiltration of various organs. In addition, the liver of this mutant demonstrated glycogen depletion, hepatic fibrosis and inflammation of the bile ducts¹⁴⁷.

A second AhR null mutant was generated by Prof. Fujii-Kuriyama's group replacing part of the exon 1 with the bacterial galactosidase gene¹⁴⁸. These animals exhibit the highest postnatal lethality of all AhR KO mice (50%).

The most widely used AhR KO strain was developed by Prof. Bradfield and collaborators (AhR^{tm1Bra}). They targeted exon 2, which encodes the basic/helix-loop-helix domain, known to be required for DNA recognition and dimerization with ARNT¹⁴⁹. Even though this strain has shown very low postnatal lethality, it presents other immune and hepatic defects such as smaller periarteriolar lymphatic sheets (PALS), larger spleens, prolonged extramedullary hematopoiesis and impaired hepatic fat metabolism^{150,151}.

In a comparison between the three AhR deficient mutant lines published by Prof. Esser, they all share some features including liver pathology, decreased fertility, slower growth rate, elevated retinoic acid levels, TCDD resistance, a patent ductus venosus, and failure to induce CYP1A1 and CYP1A2. Noteworthy, AhR KO mice present a spectrum of hepatic defects due to the crucial role of AhR in liver growth and development. For instance, liver size is

dramatically reduced to approximately half of the size of WT mice. Fibrosis is frequently observed and liver tumors develop in a proportion of the animals¹⁵⁰.

The AhR KO mouse strains have been crucial to elucidate AhR's immunomodulatory functions that go beyond its role as an environmental sensor, including repercussions in development, reproduction, immunology and gut-microbiome interactions derived from AhR signaling^{122,152}. For example, AhR KO mice helped to describe AhR's role in peripheral myelination. AhR ablation in mice causes locomotor defects, induces thinner myelin sheaths and causes dysregulation of myelin gene expression and developmental markers in the peripheral nervous system¹⁵³.

1.4.6 AhR modulates the crosstalk between the intestinal immune system, diet and microbiota

In the last decade, most attention on AhR research focused on its functions as master regulator of peripheral immunity affecting CNS inflammation and integrating environmental signals. AhR activity can be regulated by dietary components derived from cruciferous vegetables such as broccoli and Brussels sprouts^{69,76,154}.

The majority of dietary AhR ligands are plant derived compounds including flavonoids, glucosinolates, stilbenes, carotenoids and some indoles¹⁵⁵. For example, indole-3-carbinol (I3C) uptake from ingested cruciferous vegetables leads to high affinity AhR ligands production in the stomach, such as indolo-[3,2-b]-carbazole (ICZ) and 3,3'-diindolymethane (DIM)^{156,157}.

Most of these ligands are able to enter AhR expressing cells forming the intestinal epithelium and immune system. They trigger AhR nuclear translocation and targeted gene expression, including CYP1A1 and CYP1A2¹⁵⁸.

It has been shown that natural AhR ligands modulate Th17 cell differentiation *in vivo* and *in vitro*¹⁵⁹. AhR signaling is required in Th17 T cells obtained from C57BL/6J mice to produce IL22^{130,160,161}. CD4⁺ T cells from AhR KO mice can develop Th17 cells but when confronted with AhR ligands fail to produce IL22¹³⁰.

In humans, AhR mediates IL22 production in Th22 cells¹⁶². IL22 is expressed at barrier surfaces by mouse and human cells and its signaling plays an important role in antimicrobial immunity, maintenance and inflammation of the bowel¹⁶³.

Another major source of IL22 is produced by cells from the ILC family, including NK and lymphoid tissue inducer (LTi) cells. In this way, AhR ligands derived from the diet or microbiota not only regulate IL22 production, but also the maintenance, survival and proliferation of Ror γ t+ ILC in the gut and other mucosal barriers^{75,164,165}.

AhR expression in ILC3 has been relatively well studied in the gut because of its repercussions in other immune compartments. For instance, deletion of AhR in ILC3 impairs IL22 production decreasing the gut epithelial cells production of antimicrobial peptides. This proinflammatory stimulus leads to an increase of segmented filamentous bacteria (SFB) and induces Th17 responses^{143,144}.

AhR mediates the interaction between ILC3 and microbiota. Animals lacking caspase recruitment domain family member 9 (CARD9) present altered microbiota and are unable to metabolize tryptophan into AhR ligands. The catabolism of the essential amino acid tryptophan into kynurenine by the tryptophan 2,3-dioxygenase (TDO) or indoleamine 2,3-dioxygenase (IDO) provides a major source of AhR ligands. Therefore an impairment of tryptophan metabolism in the microbiota causes a decrease in the ILC3 and consequently, in IL22 production^{140,166,167}.

IDO1 can be induced in intestinal macrophages, epithelial and DC by different stimuli such as proinflammatory cytokines, toll like receptor ligands and interactions with costimulatory molecules. During infectious diseases IDO1 activity controls pathogen growth and T_{regs} expansion by metabolizing the available tryptophan into kynurenine. IDO1 response could either inhibit bacteria proliferation through amino acid – deprivation or modulate T cell response by generating tryptophan metabolites and AhR ligands¹⁶⁸.

AhR's genomic activity via tryptophan derived ligands could lead to IDO1 transcription via AhR responsive elements binding¹⁶⁹. Besides acting as a transcription factor, AhR can act as E3 ubiquitin ligase and assemble with cullin 4B to form the ubiquitin ligase CUL4B^{AHR} complex. Different proteins are targeted by this complex for proteasomal degradation, such as IDO1¹⁴¹, β catenin¹⁷⁰, estrogen and androgen receptors^{171,172}.

AhR expression is essential for tertiary lymphoid tissue formation such as cryptopatches and intestinal lymphoid follicles¹⁵⁵ and is involved in the proliferation of colonic crypt stem cells. Therefore, AhR deficiency has a significant impact on the gut immune system leading to ILC3 and IEL loss, impairment of IL22 secretion, disruption of the intestinal epithelium and dysregulation of intestinal bacteria^{136,173}.

1.4.7 EAE modulation by AhR ligands

AhR activation during EAE induction has different repercussions in the immune system depending on the ligand. Stimulation at the time of EAE induction with the endogenous AhR agonist FICZ increased the number of IL17 and IL22 producing CD4⁺ T cells quantified in the spinal cord of C57BL/6J mice. In contrast, MOG₃₅₋₅₅ immunized AhR KO animals showed a reduced production of IL17 and no IL22 was detectable regardless of FICZ stimulation^{130,160,161}.

Differently from FICZ stimulation, AhR activation by 2-(1'H-indole-3'-carbonyl)-thiazole-4-carboxylic acid methyl ester (ITE) suppressed EAE in MOG₃₅₋₅₅ immunized C57BL/6J mice. Daily administration of ITE from the day of immunization induced tolerogenic DC that supported the differentiation of FoxP3⁺ T_{regs}¹⁷⁴.

Besides the non-toxic endogenous ligands (FICZ and ITE), the high-affinity AhR agonist TCDD has been tested in the EAE model. A single TCDD i.p. injection on the day before MOG₃₅₋₅₅ immunization inhibited EAE inducing T_{regs} expansion, decreasing IL17 secretion and producing higher levels of TGF β . TCDD oral administration also prevented EAE development and had a dose dependent effect on EAE induction¹⁴².

AhR regulates inflammation by affecting different components of the immune system. AhR, as well as its target gene CYP1B1, are upregulated in astrocytes through type I interferons (IFN-I) signaling after active immunization with MOG₃₅₋₅₅. Astrocytes stimulated with IFN β activate the JAK1-STAT signaling pathway and induce AhR expression. Furthermore, the knock down of IFN-I in astrocytes reduced the AhR expression and induced EAE worsening, suggesting a role of interferons limiting CNS inflammation through AhR signaling¹²⁶.

Additionally, certain quinolone-3-carboximide based drugs intended for the treatment of autoimmune diseases and tested in the EAE model are effective AhR activators¹⁷⁵. The protective effect of Laquinimod, Tasquinimod and Paquinimod against EAE is mediated by AhR and affect AhR battery genes in a distinct manner^{176,177}.

1.5 Laquinimod

Laquinimod is an orally active quinoline-3-carboximide with AhR agonistic properties formulated as a potential DMT for MS¹⁷⁸⁻¹⁸¹. It has been modified from its predecessor roquinimex (linomide) to increase efficacy in EAE models and improve its toxicological profile¹⁸²⁻¹⁸⁵. As a small synthetic molecule, Laquinimod has the ability to freely cross the BBB without requiring further active transport. It has a high bioavailability (80-90%) and a low rate of total clearance. It is quickly absorbed in the gut reaching its maximum concentration in the plasma within two hours after administration. Laquinimod is normally eliminated in the urine after being metabolized by the cytochrome P450 (CYP) isoenzyme, CYP3A4 in the liver microsomes^{180,186-188}.

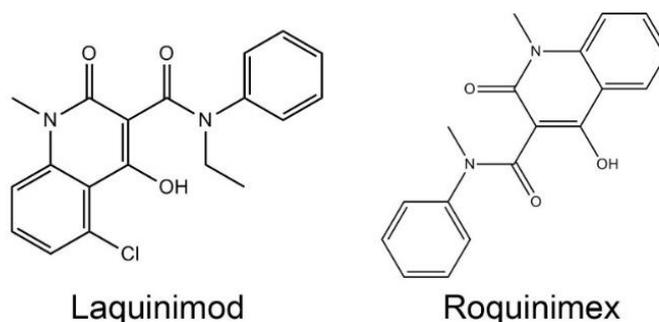

Figure 1. Structure of Laquinimod and Roquinimex. Laquinimod (5-chloro-N-ethyl-4-hydroxy-1-methyl-2-oxo-N-phenyl-1,2-dihydroquinoline-3-carboxamide), also known as ABR-215062 or nervertra, is structurally related to roquinimex (linomide).

1.5.1 Laquinimod mediated EAE suppression

Preclinical studies demonstrated that Laquinimod treatment inhibits acute and chronic relapsing EAE in C57BL/6 and SJL/J mice, respectively. Inflammatory cell infiltration, spinal cord demyelination and axonal loss were significantly reduced by daily oral administration of Laquinimod from the day of immunization (preventive regimen) in MOG₃₅₋₅₅ immunized C57BL/6 mice^{188,189}.

Moreover, VLA-4 mediated cell adhesion and proinflammatory cytokine production by Th1/Th17 responses were downmodulated in treated mice¹⁹⁰. Laquinimod was shown to modulate the adaptive T cell response via its effect on the antigen presenting cell (APCs) compartment¹⁸².

Similarly, EAE was abolished in SJL/N mice immunized with mouse spinal cord homogenate (MSCH) using daily oral dosage of Laquinimod¹⁸³. Laquinimod was also shown to inhibit EAE in Lewis rats, preventing CD4⁺ T cells and macrophages to infiltrate into the CNS and favoring Th2/Th3 cytokines^{191,192}. Using different EAE protocols, Laquinimod has shown immunomodulatory properties affecting different immune cells, for instance APCs and T cell compartments¹⁸⁸.

Experiments using AhR KO animals showed that Laquinimod's therapeutic effect is completely abolished in the absence of AhR¹⁹³. In addition, bone marrow chimera experiments demonstrated that AhR deletion in the immune system completely revokes the therapeutic effect of Laquinimod, while AhR deletion in the CNS partially affects Laquinimod's protective effect in the EAE model¹⁹⁴. These results suggest that Laquinimod might have additional neuroprotective properties.

Besides its immunomodulatory effect, Laquinimod has shown neuroprotective actions such as brain-derived neurotrophic factor (BDNF) modulation^{195,196} and axonal protection^{189,197} in the EAE model and MS patients. In the cuprizone induced demyelination model, Laquinimod prevented demyelination, oligodendroglial apoptosis, astrocytic activation and microglia infiltration¹⁸⁹.

1.5.2 Clinical trials

In phase II placebo – controlled trials, Laquinimod showed a tolerable safety profile in patients. Daily treatment led to a reduction in the number of enhancing MRI lesions compared to placebo^{198,199}, leading to further studies. Thereafter, orally administered Laquinimod (0.6 or 1.2 mg per day) was tested in three randomized phase III clinical trials, namely ALLEGRO, BRAVO and CONCERTO studies, all of them multinational, multicenter, double blind, and placebo-controlled.

The first two, ALLEGRO (Assessment of OraLLaquinimod in PrEventing ProGRession in Multiple SclerOsis) and BRAVO (Benefit-Risk Assessment of AVonex and LaquinimOd) trials, revealed Laquinimod's clinical efficacy, including reduction of disability progression, relapse rate and the number of gadolinium enhancing lesions^{200–203}.

In a third study, CONCERTO²⁰⁴, the primary endpoint of significant treatment effect on 3-month-confirmed disability progression was not achieved. However, from baseline to month 15 and compared to placebo, Laquinimod significantly reduced the risk for the first relapse (28%), relapse rate (25%) and brain volume change (40%).

1.6 Current MS therapies

MS patients can be treated by corticosteroids, plasma exchange and disease modifying therapies (DMT). Oral or intravenous corticosteroids including methylprednisolone, dexamethasone, prednisone, prednisolone and betamethasone are commonly prescribed to MS patients primarily to manage acute exacerbations or relapses through their rapid anti-inflammatory properties²⁰⁵.

Plasma exchange or immune adsorption can be used in the short term to treat severe exacerbations if steroids are ineffective or contraindicated^{206,207}. Disease modifying therapies (DMT) are prescribed to MS patients in order to reduce the number and the severity of relapses²⁰⁸. The currently accepted DMT are summarized in table 1.

| DMT (commercial name) | | Dosage/ Route/ Frequency | Efficacy in clinical trials | References | Mechanism of action | Drug class |
|-------------------------------|------------------|---|----------------------------------|---|---|-------------|
| IFN β | - 1a (Avonex) | 30 mcg / i.m. / weekly | ↓18% ARR and ↓44% CCDMS | CHAMPS ²⁰⁹ , CHAMPIONS ²¹⁰ | Different immunomodulatory effects ²¹¹ | First line |
| | - 1a (Rebif) | 44 mcg / s.c. / 3 x week | ↓32% ARR and ↓45% CCDMS | ETOMS ²¹² | Different immunomodulatory effects ²¹³ | First line |
| | - 1b (Betaseron) | 250 mcg / s.c. / every other day | ↓34% ARR, ↓30% DP and ↓50% CCDMS | BENEFIT ^{198,214} | Different immunomodulatory effects ²¹⁵ | First line |
| | - 1b (Extravia) | 0.25 mg / s.c. / every other day | ↓42% ARR, ↓16% DP and | 216–218 | Immuno-modulatory therapy for RRMS and SPMS | First line |
| Glatiramer acetate (Copaxone) | | 20 mg / s.c. / every day | ↓29% ARR and ↓45% CCDMS | 219–221, PreCISE ²²² , GLACIER ²²³ , | Induces and activates T-lymphocyte suppressor cells | First line |
| Teriflunomide (Aubagio) | | 14 mg / oral / daily | ↓31%-36% ARR, ↓26%-32% DP | TEMPO ^{224,225} , TOPIC ²²⁶ , TOWER ²²⁷ | Pyrimidine synthesis inhibition in lymphocytes | First line |
| Dimethyl fumarate (Tecfidera) | | 240 mg / oral / 2 x day | ↓44%-53% ARR, ↓38% DP | CONFIRM ²²⁸ , DEFINE ²²⁹ , ENDORSE ²³⁰ , ESTEEM ²³¹ | Induces apoptosis in activated T cells through Th2 cytokines | First line |
| Natalizumab (Tysabri) | | 300 mg / i.v. / monthly | ↓68% ARR, ↓42% DP | SENTINEL ²³² , TIMER ²³³ , AFFIRM ^{234,235} | Blockade of adhesion molecules that inhibit T cell traffic across the BBB | Second line |
| Fingolimod (Gilenya) | | 0.5 mg / oral / daily | ↓48%-54% ARR, ↓30% DP | TRANSFORMS ^{236–239} , FREEDOMS ^{240,241} , FREEDOMS II ²⁴² | S1PR receptor modulator and Immuno-suppressant | First line |
| Alemtuzumab (Lemtrada) | | 30 mg x day / i.v. / 3 x week for 12 weeks | ↓49%-55% ARR ↓42% DP | CAMMS223 ^{243,244} , CARE MS I ²⁴⁵ , CARE MS II ²⁴⁶ | Anti-CD52 monoclonal antibody that depletes T and B lymphocytes | Second line |
| Mitoxantrone (Novantrone) | | 12 mg/m ² x 3 months or 8 mg/m ² monthly / i.v. | ↓65% relapse risk and ↓66% DP | 247–249 | DNA intercalator and topoisomerase II enzyme activity inhibitor | Second line |

Table 1. First and second line approved drugs for MS treatment. Abbreviations: ↓: reduction; ↑: increase; ARR: Annualized relapse rate; CCDMS: conversion to clinically definite multiple sclerosis; DMT: disease modifying treatment, DP: disability progression; INF: interferon; i.m.: intramuscular; i.v.: intravenous; s.c.: subcutaneous.

The escalating and the induction therapies are the two major treatment approaches for MS. Mildly or moderately affected MS patients usually receive a first line therapy with moderate

efficacy but high safety profile before changing to a second line medication with more safety risks (escalating approach). The induction approach is the initial use of a highly effective second line treatment in order to obtain a rapid remission of a highly active disease^{250,251}.

1.7 Aims

The AhR molecular pathway is activated by different environmental factors affecting the immune system. Contradicting results have been obtained using MOG₃₅₋₅₅ immunized C57BL/6J mice by stimulation with different high affinity AhR agonists such as FICZ, ITE and TCCD^{130,142,174}. It remains unknown if physiological concentrations of AhR ligands in the regular diet have immunomodulatory properties influencing spontaneous EAE incidence and severity and if so, which cell type is the most relevant player for AhR mediated modulation of the CNS autoimmunity.

The central aim of this project is to evaluate the function of AhR in CNS autoimmunity and its modulation through physiological ligands found in the diet. In order to get an insight through the AhR's mechanistic regulation, the present work intends to elucidate which cellular players are required to mediate the immunomodulatory effect of the clinically relevant AhR agonist, Laquinimod.

In detail, the present thesis aims:

- a) To assess if EAE incidence and severity can be influenced by increasing the AhR ligands of cruciferous vegetables in the diet of OSE mice.
- b) To evaluate AhR's immunomodulation in DC, CD4⁺ T cells and astrocytes by generating cell specific AhR KO mice in the OSE mouse model using the Cre-Lox system.
- c) To investigate how clinically relevant cell specific AhR deficiencies in OSE mice affect APCs activation, antibody production and T cell activation.
- d) To identify relevant AhR targets that mediate the therapeutic efficacy of the putative AhR ligand, Laquinimod, in CNS autoimmunity.

2. MATERIALS AND METHODS

2.1 Materials

2.1.1 Reagents

| Reagent | Supplier |
|--|---|
| Agarose | StarLab GmbH, Hamburg, Germany |
| BD FACS Clean | BD Biosciences, Franklin Lakes, NJ, USA |
| BD FACS Flow | BD Biosciences, Franklin Lakes, NJ, USA |
| BD FACS Lysing Solution, 10x | BD Biosciences, Franklin Lakes, NJ, USA |
| BD FACS Shutdown Solution | BD Biosciences, Franklin Lakes, NJ, USA |
| BD Pharm Lyse, 10x | BD Biosciences, Franklin Lakes, NJ, USA |
| β -Mercaptoethanol | Sigma Aldrich, St. Louis, MO, USA |
| Boric acid | Merck Millipore, Darmstadt, Germany |
| CaCl ₂ (calcium chloride) | Sigma Aldrich, St. Louis, MO, USA |
| Chloral hydrate | Merck Millipore, Darmstadt, Germany |
| Cytofix | BD Biosciences, Franklin Lakes, NJ, USA |
| Cytofix/Cytoperm | BD Biosciences, Franklin Lakes, NJ, USA |
| (DAPI) Diamidino-2-phenylindole, 1 mg/ml | Thermo Scientific, Waltham, MA, USA |
| DMEM (Dulbecco's Modified Eagle's medium) | Sigma Aldrich, St. Louis, MO, USA |
| dNTP (desoxynucleoside triphosphate) mix | Thermo Scientific, Waltham, MA, USA |
| DTT (Dithiothreitol) | Sigma Aldrich, St. Louis, MO, USA |
| EDTA (ethylenediamine tetraacetic acid) | Carl Roth, Karlsruhe, Germany |
| FCS (fetal calf serum) | Sigma Aldrich, St. Louis, MO, USA |
| Fluorescence mounting medium | Dako, Deutschland GmbH, Hamburg |
| FoxP3 Fixation/Permeabilization Concentrate | eBioscience, San Diego, CA, USA |
| FoxP3 Fixation/Permeabilization Diluent | eBioscience, San Diego, CA, USA |
| FoxP3 Permeabilization buffer, 10x | eBioscience, San Diego, CA, USA |
| GelRed nucleic acid gel stain, 10 000x | Biotium, Fremont, CA, USA |
| GeneRuler, 100 base pairs (bp) DNA ladder plus | Thermo Scientific, Waltham, MA, USA |
| Go-Taq DNA polymerase buffer, 5x | Promega, Madison, WI, USA |
| HBSS (Hank's buffered salt solution) | Sigma Aldrich, St. Louis, MO, USA |
| HCl (hydrochloric acid) | Merck Millipore, Darmstadt, Germany |
| HEPES (4-(2-hydroxyethyl)-1-piperazineethanesulfonic acid) | Sigma Aldrich, St. Louis, MO, USA |
| H ₂ O ₂ (oxygen peroxide) | Sigma Aldrich, St. Louis, MO, USA |
| H ₂ SO ₄ (sulfuric acid) | Sigma Aldrich, St. Louis, MO, USA |

| Reagent | Supplier |
|--|---|

| Trypan blue | Sigma Aldrich, St. Louis, MO, USA |
| Xylene | Chemsolute, Th. Geyer GmbH & Co. KG, Renningen, Germany |

Table 2. Reagents used in the different experimental procedures.

2.1.2 Buffers and solutions

| Solution | Components |
|---|--|
| 80% Percoll solution | 80% Percoll in DMEM ^{high-Glu} |
| Agarose gel | 2% agarose in TBE (Tris/Borate/EDTA) buffer |
| CFA (Complete Freund's Adjuvant) | 85% paraffin oil 15% mannide monooleate 6.7 mg/ml mycobacterium tuberculosis H37R |
| Chloral hydrate 14% anesthesia | 14 g chloral hydrate in 100 ml bidistilled H ₂ O |
| DMEM ^{high-Glu} (Dulbecco's Modified Eagle's medium high glucose) | 4500 mg/L glucose 2% FCS in DMEM |
| ELISA blocking buffer | 5% BSA in PBS |
| ELISA wash buffer | 0.05% Tween 20 in PBS |
| ELISA stop solution | 1 N H ₂ SO ₄ in H ₂ O |
| FACS buffer | 2% FCS in PBS |
| Fixation buffer | 4% paraformaldehyde (PFA) in PBS |
| Immunization emulsifier | 1:1 (v/v) mixture of CFA (supplemented with 5 mg/ml H37Ra) and 2 mg/ml MOG ₃₅₋₅₅ in PBS |
| Master mix (40% Percoll solution) | 40% Percoll in DMEM ^{high-Glu} |
| MACS buffer | 0.5% BSA 2 mM EDTA in PBS |
| Percoll gradient medium | 40 or 80% Percoll 2% FCS DMEM, high glucose (4.5 g/L D-glucose) |
| RPMI _{complete} (Roswell Park Memorial Institute 1640 medium complete) | RPMI 1640 10% FCS 1 mM sodium pyruvate 1x 1x non-essential amino acids 50 μM β-mercaptoethanol 0.1 mg/ml streptomycin 2 mM L-glutamine |
| Small intestine digestion solution | 100 μl collagenase D (100 mg/ml) 100 μl DNase I (100 mg/ml) 10% FCS |
| Small intestine predigestion solution | 10 mM CaCl ₂ 20 ml DMEM 1 mM DTT 5 mM EDTA 10% FCS |
| Tail Lysis Buffer | 500 ml HBSS 0.1 M Tris-HCl 200 mM NaCl 0.2% SDS (sodium dodecyl sulfate) 5 mM EDTA in bidistilled H ₂ O, adjusted pH = 8.5 |
| TBE (Tris/Borate/EDTA) buffer | 90 mM Tris, 90 mM boric acid 2 mM EDTA in bidistilled H ₂ O |

| FlowJo 7.6.1 | Flow cytometry data analysis | Tree Star Inc., Ashland, OR, USA |
| GraphPad Prism 6 | Statistical analysis | GraphPad software Inc., La Jolla, CA, USA |

Table 15. List of software used for data acquisition and analysis.

2.2 Transgenic mouse models

All transgenic mice were housed at the animal facility of the University Medical Center Göttingen (UMG) under specific pathogen free (SPF) conditions. Animals were exposed to constant 12h/12h dark/light cycles and supplied with food and water ad libitum. All mice transported from outside the animal facility or to a new room (inside the bioterium) received one week of acclimation before the experiment started.

Animal experiments were performed in agreement with the European Communities Council Directive of 24 November 1986 (86/EEC) and were approved by the Government of Lower Saxony, Germany. All genetically modified mice used for breeding, *in vivo* and *ex vivo* experiments are summarized in tables 16 and 17.

2.2.1 C57Bl/6J mice

6-8 weeks old female C57Bl/6J mice were purchased from Charles River laboratories, Sulzfeld, Germany or from the animal facility of the University Medical Center Göttingen.

2.2.2 2D2 mice

MOG specific T cell receptor (TCR) transgenic mice, which are also known as TCR^{MOG}. Bettelli and colleagues developed the transgenic mouse model by using a CD4⁺ MOG₃₅₋₅₅ specific T cell clone called 2D2, which expresses a TCR conformed by a V α 3.2 and V β 11 chains. Approximately 30% of the 2D2 mice spontaneously develop optic neuritis without showing clinical or histological signs of EAE. 2-4% of the mice develop spontaneous EAE.

2.2.3 Th/+ mice

Knock in mice also referred as IgH^{MOG}, were developed by Litzemberger and collaborators by inserting a transgenic IgH chain variable gene of the 8.18C5 MOG specific monoclonal antibody. Around 30% of all B cells in bone marrow and periphery are MOG specific. Consequently, high titers of MOG specific IgM antibodies are present in the sera of these mice. In contrast to 2D2 mice, the Th/+ transgenic mouse line does not spontaneously develop EAE. Upon active immunization or the adoptive transfer of MOG specific T cells, MOG specific

antibodies are switched to IgG1 and IgG2a isotypes leading to an earlier disease onset, increased EAE incidence and severity compared to non-transgenic animals²⁵².

2.2.4 OSE mice

Krishnamoorthy and colleagues generated a double transgenic mouse model that spontaneously develops CNS demyelinating disease. They were named OSE or opticospinal EAE mice because the CNS lesions are located almost exclusively in the optic nerve and spinal cord. The mouse strain was generated by crossing the previously described 2D2 mice with Th/Th+ double transgenic mice on a C57BL/6 background. As a result, 50% of these mice express both, MOG specific T and B cells. OSE mice develop spontaneous EAE under specific pathogen free (SPF) conditions with a frequency of 30-50% depending on the animal facility¹⁰¹.

| Mouse model | Expression method | Developer / Reference | Donating researcher |
|-------------|---|---|--|
| 2D2 | Transgene insertion: V α 3.2J α 18 region of TCR α and V β 11DJ β 1,1 region of TCR β from the 2D2 T cell clone inserted into TCR expression cassettes | Esther Bettelli, Brigham and Women's Hospital and Harvard Medical School ²⁵³ | Generous gift from the group of Prof. Vijay K. Kuchroo, Harvard Medical School |
| Th/Th+ | Targeted insertion of the rearranged VDJ gene of the H chain from the MOG specific hybridoma 8.18-C5 | Tobias Litzenburger, Max Plank Institute of Neurobiology ²⁵² | Generous gift from the group of Prof. Hartmut Wekerle |
| OSE | Double transgenic mice (derived from 2D2 and Th/+ mice breeding) | Gurumoorthy Krishnamoorthy, Max Plank Institute of Neurobiology ¹⁰¹ | Crossbreeding |

Table 16. Transgenic mouse models used for breeding, *in vivo* and *in vitro* experiments. Abbreviations: OSE: opticospinal EAE.

2.3 Breedings

All transgenic mice were generated from in-house breeding colonies at the UMG animal facility and backcrossed to C57BL/6 for more than 12 generations. Animals were mated between 6 and 8 weeks of age.

2.3.1 Cell specific AhR KO mouse strains

To examine the repercussions of AhR signaling in certain immune players, a variety of cell specific Cre lines (CD11c^{Cre}, FoxP3^{Cre}, GFAP^{Cre} and CD4^{Cre}) were crossed to AhR^{fl/fl} mice (table 17) to specifically delete AhR in DC, T_{regs}, astrocytes and CD4⁺ T cells. The generated AhR^{ΔDC}, AhR^{ΔTreg}, AhR^{ΔAstro} and AhR^{ΔCD4} mice were used in the context of actively induced EAE, by immunization with MOG₃₅₋₅₅ and CFA as described in 2.4.2.

On the other hand, the same transgenic lines were bred to 2D2 and Th/Th+ mice to obtain: OSE AhR^{fl/fl}, OSE AhR^{ΔCD4}, OSE AhR^{ΔTreg}, OSE AhR^{ΔAstro} and OSE AhR^{ΔDC}. Using the breeding strategy depicted in figure 2, the repercussions of a cell specific AhR deletion on a spontaneous EAE model were studied.

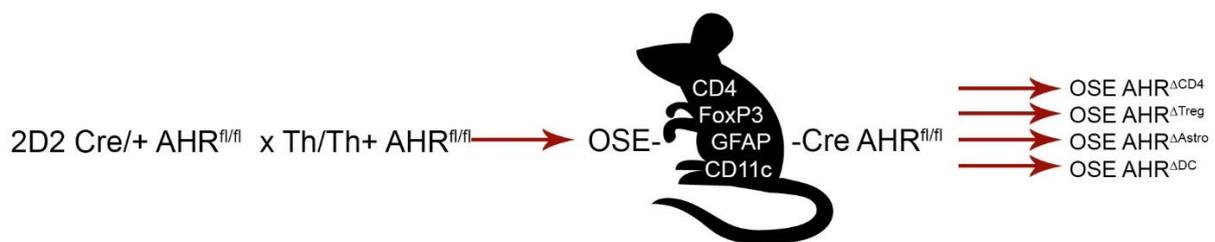

Figure 2. Breeding strategy used to produce four different cell specific AhR KO mouse strains that develop spontaneous EAE. The different strains are double transgenic (opticospinal or OSE) mice generated by crossing 2D2 and Th/Th+ animals: OSE AhR^{ΔCD4}, OSE AhR^{ΔTreg}, OSE AhR^{ΔAstro} and OSE AhR^{ΔDC}. Taking advantage of the Cre/Lox system, cell specific AhR KO were produced by breeding AhR^{fl/fl} mice with animals expressing an active Cre recombinase controlled by a defined promoter (CD4^{Cre}, FoxP3^{Cre}, GFAP^{Cre} and CD11c^{Cre}).

To further characterize the APCs compartment of the OSE mice, reporter animals expressing an enhanced green fluorescent protein (EGFP) under the control of a CX3CR1 promoter were bred to the OSE AhR^{ΔDC} or OSE AhR^{fl/fl} control littermates generating OSE AhR^{ΔDC} CX3CR1^{EGFP/+} and OSE AhR^{fl/fl} CX3CR1^{EGFP/+} control mice.

2.3.2 AhR^{fl/+} CD11c^{Cre+} R26^{eYFP} mice (CD11c specific AhR KO)

To investigate AhR deletion in CD11c⁺ DC cells, AhR competent (AhR^{+/+}) or AhR KO (AhR^{-/-}) CD11c^{Cre} mice were bred with AhR^{fl/fl} animals to generate AhR^{fl/+} CD11c^{Cre+} controls and AhR^{fl/-} CD11c^{Cre+} offspring. The CD11c^{Cre+} transgenic mice are described in table 17 and harbor Cre recombinase under the control of a CD11c promoter²⁵⁴.

The AhR^{fl/fl} animals were previously crossed to R26^{eYFP} transgenic mice carrying an enhanced yellow fluorescent protein (eYFP) inserted into the *Gt(ROSA)26Sor* locus and blocked by an upstream *loxP* flanked STOP sequence²⁵⁵. The breeding of AhR^{fl/fl} R26^{eYFP} animals with AhR^{+/-} CD11c^{Cre+} led to the deletion of the AhR targeted gene in one allele of CD11c⁺ cells. Cre recombinase activation deleted the STOP sequence in CD11c⁺ cells and was reported by eYFP expression.

The generated mice (AhR^{fl/+} CD11c^{Cre+} R26^{eYFP} and AhR^{fl/-} CD11c^{Cre+} R26^{eYFP}) offered the advantage that eYFP⁺ AhR competent or AhR deficient DC can be sorted *ex vivo* for further analysis and its generation is depicted in figure 3.

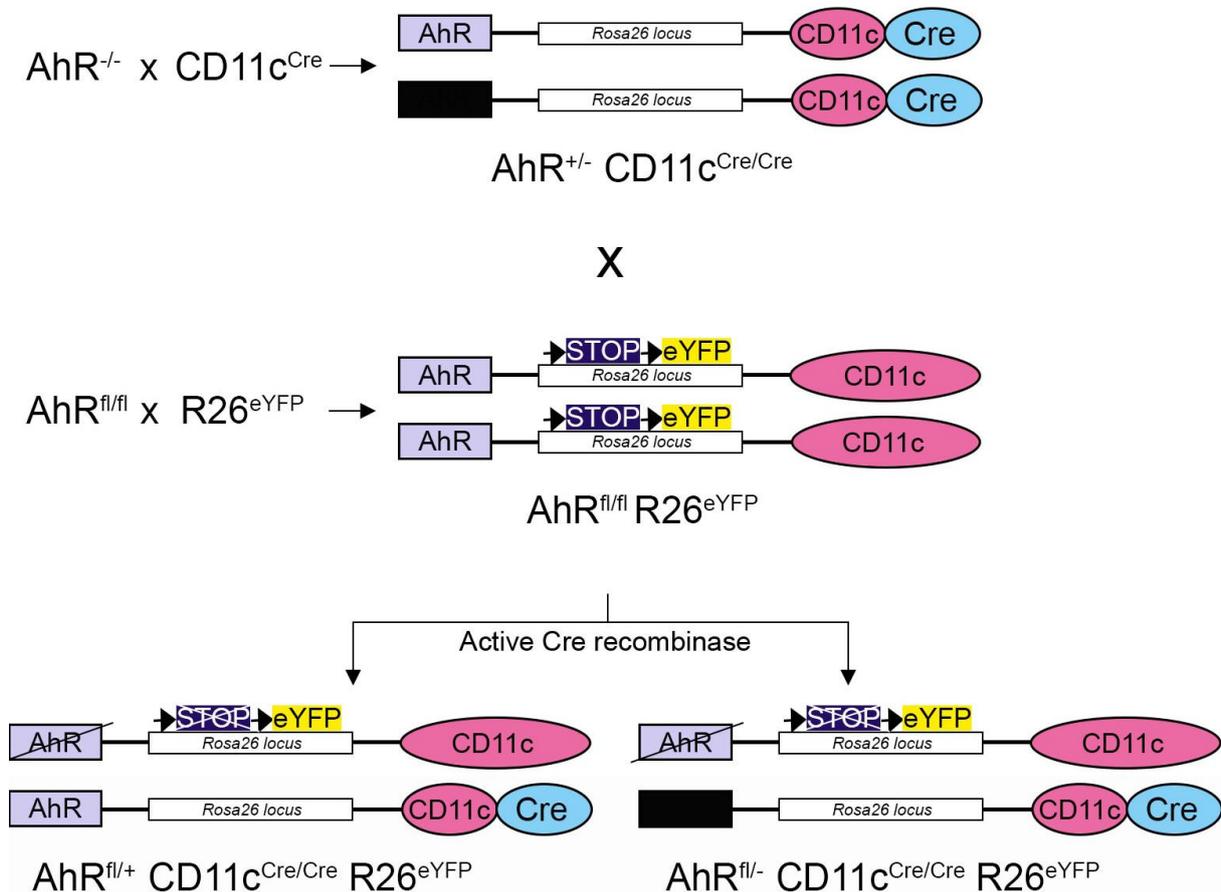

Figure 3. Breeding strategy used to generate AhR^{fl/+} CD11c^{Cre+} R26^{eYFP} and AhR^{fl/-} CD11c^{Cre+} R26^{eYFP} control mice. The transgenic animals carry a Cre recombinase active under the control of a CD11c promoter and a Cre dependent eYFP reporter gene that labels CD11c⁺ cells upon Cre recombinase activation. AhR^{fl/-} CD11c^{Cre+} R26^{eYFP} lack AhR in DC cells and AhR^{fl/+} CD11c^{Cre+} R26^{eYFP} are AhR^{+/-} in CD11c⁺ cells.

2.3.3 CD11c^{tdTomato} CX3CR1^{eGFP} transgenic line

To evaluate the different intestinal APCs populations CX3CR1^{eGFP} mice were bred with the CD11c^{Cre} and R26^{tdTomato} transgenic strains. The R26^{tdTomato} mice harbor a *loxP* flanked STOP cassette designed to prevent transcription of the red fluorescent protein variant. When they were bred to the CD11c^{Cre} mice that express Cre recombinase under the control of a CD11c promoter, the resulting offspring deleted the STOP cassette in CD11c⁺ cells marking them with tdTomato fluorescence. Because this CAG promoter driven reporter construct is inserted into the *Gt(ROSA)26Sor* locus, robust tdTomato expression is determined by the CD11c Cre recombinase.

| Target gene | Expression method | Developer / Reference | Supplier |
|--|---|---|--|
| AhR ^{tm1} | Targeted (knock out) | Christopher A Bradfield, University of Wisconsin-Madison ¹⁴⁹ | Jackson Laboratory |

Table 17. Transgenic mouse lines used to generate AhR specific knock out mice through the Cre/Lox system. Abbreviations: CX3CR1: chemokine receptor 1; EGFP: enhanced green fluorescent protein; FoxP3: forkhead box P3; GFAP: glial fibrillary acidic protein; Itgax: integrin alpha X; TM: targeted mutation; R26: rosa 26 locus; YFP: yellow fluorescence protein.

2.4 Methods

2.4.1 Genotyping of transgenic mice

PCR based genotyping of all transgenic mouse lines was performed by Ms. Katja Schulz (Department of Neuropathology, University Medical Center Göttingen).

2.4.1.1 DNA extraction

Genomic DNA was isolated from tail biopsies of AhR^{fl/fl}, AhR^{ΔCD4}, AhR^{ΔTreg}, AhR^{ΔAstro} and AhR^{ΔDC}, 2D2, Th/+, OSE AhR^{fl/fl}, OSE AhR^{ΔCD4}, OSE AhR^{ΔTreg}, OSE AhR^{ΔAstro}, OSE AhR^{ΔDC}, OSE AhR^{ΔDC} CX3CR1^{EGFP/+} and OSE AhR^{fl/fl} CX3CR1^{EGFP/+} mice at 3 weeks of age.

In order to isolate genomic DNA, the tails were digested using a mixture of 20 μl Proteinase K and 350 μl tail lysis buffer in a thermomixer at 350 rpm and 56°C overnight. Samples were centrifuged for 5 min at 13200 rpm and the supernatants were collected into new tubes. Each tube received 350 μl of isopropyl alcohol to precipitate the DNA.

All samples were carefully mixed, centrifuged and the supernatants were discarded. Subsequently, 350 μl of 70% ethanol were added before the last centrifugation step. The DNA pellet was dried for 10-15 min at 45°C in a speed vacuum concentrator and resuspended in 100 μl bidistilled H₂O.

2.4.1.2 Polymerase chain reaction (PCR)

| Gene | Vα 3.2Jα18 TCR | AhR ^{fl/fl} | CD11c ^{Cre} | CD4 ^{Cre} | GFAP ^{Cre} | FoxP3 ^{Cre} | Igh-J (8.18-C5) | CX3CR1 ^{EGFP} |

Table 18. Composition of PCR reactions used for transgenic mice genotyping. A mixture of Go-Taq DNA polymerase buffer (5x), deoxynucleotide triphosphates (dNTPs), reverse and forward primers, Go-Taq DNA polymerase, bidistilled H₂O and genomic DNA was used for all reactions. Primers were used at a concentration of 10mM; except for GFAP (100 pmol) and dNTPs at concentration of 2,5 mM; except for FoxP3 and GFAP (10 mM). All quantities are given in microliters (μl).

The PCR reaction components are listed on table 18 for each of the transgenic mouse lines and all primers are described in table 7. PCR reactions were run in a T3 thermocycler and the specific cycling conditions are described in table 19. Ethidium bromide stained PCR products were separated by electrophoresis on agarose gel at 120 volts for 60-90 minutes and the product length was evaluated using a 100 base pairs (bp) DNA ladder under UV light.

Table 19. 6 step PCR programs used in the T3 thermocycler for transgenic mice genotyping. Abbreviations: m: minutes; s: seconds.

For the genotyping of AhR^{fl/fl}, AhR^{ΔCD4}, AhR^{ΔTreg}, AhR^{ΔAstro} and AhR^{ΔDC} two PCR reactions were performed: one for the AhR^{fl/fl}, gene and one for the corresponding Cre transgene under control of a CD11c, CD4, FoxP3 or GFAP promoter. For the OSE AhR^{ΔDC}, OSE AhR^{ΔCD4}, OSE AhR^{ΔTreg}, OSE AhR^{ΔAstro} and OSE AhR^{fl/fl} CX3CR1^{EGFP/+} two additional

reactions were performed one to detect the V α 3.2J α 18 TCR gene (2D2 mice) and one for the Igh-J gene (Th/+ mice).

2.4.2 Mouse immunization with MOG₃₅₋₅₅ and EAE induction

AhR Δ DC, AhR Δ Treg, AhR Δ Astro, AhR Δ CD4 and AhR^{fl/fl} control mice were actively immunized with a subcutaneous (s.c.) injection of 50 μ l of MOG₃₅₋₅₅ emulsified in complete Freund's adjuvant (CFA, composition detailed in table 3) per groin and per axilla (200 μ g MOG₃₅₋₅₅/animal). The s.c. inoculation was accompanied by an intraperitoneal (i.p.) injection of 400 ng of pertussis toxin (PTX) on the day of immunization and two days later.

2.4.3 Clinical EAE score

All animals were observed after immunization and scored daily based on a scale of disease severity. The scale ranges from 0 (healthy) to 5 (death) as shown in table 20. Ethical standards dictate that animals reaching 3.5 should be immediately sacrificed. The animals that died because of EAE were scored 5 and the ones sacrificed for ethical reasons were documented with the last given score until the experiment ended.

| Score | Clinical signs | Description |
|-------|---|--|
| 0 | Healthy | No neurological deficits |
| 0.5 | Partially limp tail | The distal part of the tail is weak or paralyzed |
| 1 | Tail paralysis | The complete tail is flaccid and hanging loosely |
| 2 | Impair righting reflex, hind limbs weakness | Positive flip test: The mouse struggles to roll back onto its feet when laid on its back |
| 2.5 | 1 or 2 hind limbs incomplete paralysis | Hind limbs are unsteady producing wobbling when walking |
| 3 | Hind limbs complete paralysis | Front paws are very active for grasping. The mouse can easily support its own weight using only the fore paws. |
| 3.5 | Hind limbs and abdomen paralysis | The mouse lacks the strength to hang on the grid and it is not able to reach the water bottle and food located on the lid. |
| 4 | Fore limbs weakness | Inactive behavior, loss of muscular tone of all limbs |
| 4.5 | Moribund | The paralysis extends to the fore limbs, altered breathing and usually prostrated. |
| 5 | Dead | |

Table 20. Scoring scale for EAE clinical monitoring. Detailed description of the clinical signs that characterized each stage of disease severity according to the followed EAE scale.

2.4.4 Laquinimod administration

Laquinimod was dissolved in water and administered daily to the mice by oral gavage at a dosage of 25 mg/kg_{body weight} for MOG immunized mice and 50 mg/kg_{body weight} for animals transferred with B16F10 melanoma cells. Every week the animals were weighted and the dosages were adjusted accordingly. The control animals received the same volume of tap water. Laquinimod was generously provided by Teva Pharmaceutical Industries, Ltd., Netanya, Israel.

Laquinimod treatment was started on the day of immunization and continued daily for 10 days if immunological analyses were performed or for 30 days to follow the clinical disease course.

2.4.5 Preparation of single cell suspensions from the spleen for ex vivo analysis

Laquinimod or vehicle treated animals were sacrificed by cervical dislocation after anesthesia. Spleens were dissected and transferred into a 10 ml tube with cold RPMI_{complete}. This procedure was performed under the hood for the sterile acquisition of splenocytes. Unless stated otherwise, cells were washed with 10 ml of cold RPMI_{complete} and centrifuged for 10 minutes at 300 x g and 4°C.

Mechanical dissociation was used to disrupt the spleens, which were pressed through a 70 µm strainer using the plunger end of a syringe. The remaining cells were washed through the strainer, collected into 50 ml tubes and centrifuged. The pellet was resuspended in 1 ml of BD Pharm lyse solution (1:10 diluted in bidistilled H₂O) and incubated for 3 min at 37°C to lyse erythrocytes. The reaction was stopped by adding 20 ml of cold RPMI_{complete} and the cells were washed twice.

2.4.6 Cell counting with Neubauer chamber

Before being plated for FACS staining, the cells were stained with trypan blue to test cell viability and counted in a Neubauer chamber. Living cells with intact cell membranes exclude dyes such as trypan blue allowing us to differentiate between dead and viable cells.

Therefore, 10 μ l of the cell suspension were diluted 1:10 in trypan blue (previously diluted 1:10 in PBS) and transferred to the capillary gap between the chamber bottom and the cover glass. The cell concentration was determined by counting the number of cells in the four outer squares of 1 mm² of area and 1 μ l of volume using the 10x objective of the light microscope.

The concentration of cells was then calculated according to the following formula:

$$\text{Concentration (cells/ml)} = \frac{\text{Number of cells} \times 10\,000}{\text{Number of squares} \times \text{dilution}}$$

2.4.7 Isolation of lymphocytes from the small intestine

6 to 8 weeks old OSE AhR^{ΔDC}, OSE AhR^{fl/fl}, OSE AhR^{ΔDC} CX3CR1^{EGFP/+} and OSE AhR^{fl/fl} CX3CR1^{EGFP/+} animals were used to isolate lymphocytes from the gut. The small intestine was dissected leaving approximately 0.5 cm separation below the stomach and 0.5 cm above the caecum, transferred to a Petri dish with cold PBS and cut in ~5 cm long pieces. Each segment was cleaned from the remaining connective tissue, fat and blood vessels. The faeces were rinsed from the intestine pieces using a 10 ml syringe filled with cold PBS and 18G needle. The intestinal lumen was flushed with approximately 40 ml per mouse or until no remaining fecal matter was observed.

2.4.7.1 Isolation of lymphocytes from the Peyer patches

5 to 10 Peyer's patches (PP) per mouse were removed from the intestines of each mouse using small scissors and curved tweezers to hold tight these structures. After excision, all PP were transferred into a 50 ml tube with cold RPMI_{complete} and remained on ice until further treatment. The content of the tube with the PP was filtered through a 70 μ m strainer and the tissue was disrupted by mechanical dissociation using the plunger of a 5ml syringe. The strainer was flushed with 10 ml cold RPMI_{complete}.

2.4.7.2 Isolation of intraepithelial lymphocytes

After removing the PP, the intestine segments were opened longitudinally and further cut in 0.5 cm pieces. The sections obtained were washed 3 times with cold PBS using a metallic

sieve and transferred into a 50 ml tube with 10 ml prewarmed predigestion solution. This buffer contains EDTA (cation chelant) and DTT (reducing agent), which have been shown to increase intestinal intraepithelial lymphocytes (IEL) isolation purity²⁶³.

The tissue was vigorously mixed using a tube rotator at maximum speed for 10 to 15 minutes at 37°C and vortexed for 15 seconds. Subsequently, the 10 ml content containing detached IEL was filtered through a 70 µm strainer and collected into a 50 ml tube. The strainer was rinsed with 5 ml cold PBS and the tissue was transferred into a new tube with fresh 15 ml prewarmed predigestion solution. The tube was placed again inside the warming chamber and the same procedure was repeated 3 times until collecting a final volume of 45 ml IEL suspension.

2.4.7.3 Isolation of lamina propria lymphocytes

The remaining predigested tissue was washed 3 times with cold PBS, cut into smaller pieces and transferred into a 50 ml tube with 5 ml prewarmed digestion solution. The dissociation buffer contains collagenase D and DNase I for enzymatic degradation of the connective tissue forming the lamina propria (LP) underneath the intestinal epithelium.

Samples were mixed using a rocking platform at 190 rpm for 15 to 20 minutes at 37°C, and vortexed for 20 seconds. The 5 ml content was filtered through a 40 µm strainer and collected into a 50 ml tube. 5 ml of cold RPMI_{complete} were used to rinse the strainer. Next, the tissue was transferred into a new tube with fresh 5 ml prewarmed digestion solution and placed again on the rocking platform. The same procedure was repeated 4 times, generating a final volume of 40 ml containing the isolated lamina propria lymphocytes (LPL).

Cells obtained from OSE AhR^{ΔDC} CX3CR1^{EGFP/+} and OSE AhR^{fl/fl} CX3CR1^{EGFP/+} animals were always protected from light exposure. During incubation periods the cells always remained on ice and centrifugations ran for 10 minutes at 400 x g at 4°C if not stated differently.

2.4.7.4 Separation of lymphocytes using a Percoll gradient

The IEL and LPL obtained from the predigestion and digestion steps were centrifuged and resuspended in 10 ml DMEM^{high-Glu}. After an additional centrifugation, cells were resuspended in 8 ml master mix (40% Percoll solution), thoroughly mixed and gently added onto 5 ml of 80% Percoll solution, which was previously poured into a 15 ml tube as shown in figure 4. The tubes containing 40 and 80% Percoll phases corresponding to either IEL or LPL (2 per mouse) were centrifuged for 25 minutes at 400 x g at 20°C without break and deceleration.

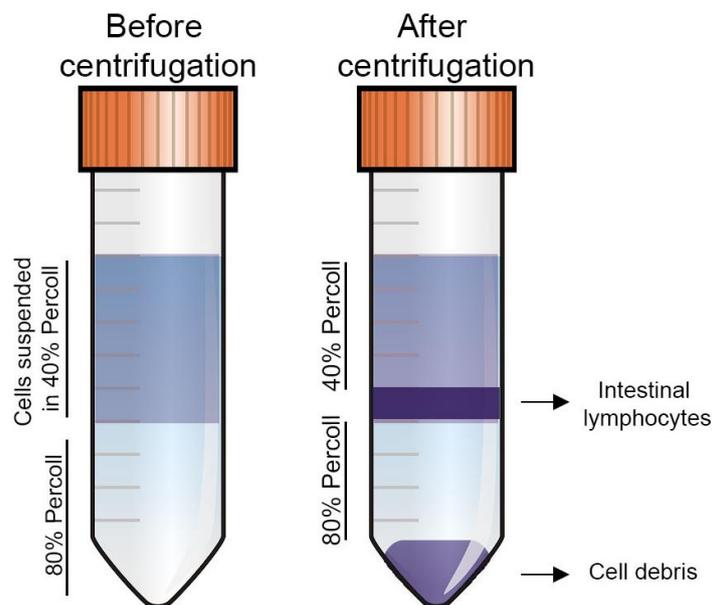

Figure 4. Schematic representation of the tubes containing 40 and 80% Percoll phases before and after the Percoll gradient centrifugation. This procedure was used to separate either intraepithelial or lamina propria lymphocytes from the small intestines.

After the Percoll gradient centrifugation, a fraction of the 40% Percoll upper layer was removed using a glass pipette connected to a vacuum pump in order to have better access to the layer beneath comprising the intestinal lymphocytes. Using a 1 ml micropipette, the intestinal lymphocytes from the Percoll interphase were transferred into a new tube containing 10 ml of FACS buffer.

The 3 tubes obtained from each mouse (containing IEL, PP and LP lymphocytes) were centrifuged and resuspended in FACS buffer. Cells were counted as described in section 2.4.6

and plated in 96 well plates (500 000 cells per well) before proceeding to extra and intracellular FACS stainings.

2.4.8 Flow cytometry staining and analysis

Once the cell concentration was determined, single cell suspensions were transferred to round bottom 96 well plates ($0.5-1 \times 10^6$ cells per well), centrifuged and washed twice. Unless stated otherwise, cells were washed with 200 μ l of cold FACS buffer per well and centrifuged for 10 minutes at $300 \times g$ and 4°C .

2.4.8.1 Detection of extracellular proteins

For extracellular FACS stainings a master mix was prepared beforehand with 8 fluorochrome labeled antibodies diluted 1:200 and BD Fc block (anti-CD16/CD32) diluted 1:100 in FACS buffer (table 12). 50 μ l of staining solution was added per well. Cells were incubated with the master mix in the dark for 12 minutes at 4°C , centrifuged and washed twice.

2.4.8.2 Intracellular detection of FoxP3

Intracellular detection of the transcription factor FoxP3 was performed after staining all surface molecules as described in the previous section. Subsequently, cells were incubated and fixed in FoxP3 fixation concentrate diluted 1:4 in the dilution buffer for 1 hour. After centrifugation, cells were washed twice with FoxP3 permeabilization buffer diluted 1:10 in bidistilled H_2O . After centrifugation, cells were resuspended with the anti-FoxP3 antibody diluted 1:100 in permeabilization buffer and incubated for 30 minutes at 4°C in darkness. Next, 100 μ l of staining solution were added per well. Cell suspensions were centrifuged and washed twice.

2.4.8.3 Intracellular detection of IFN γ and IL17

Ionomycin is a calcium ionophore and PMA is a small organic compound that freely diffuses through the cell membrane. They stimulate cytokine secretion by activating calcium release and protein kinase C (PKC) signaling, respectively^{264–267}. In order to quantify CD4^+ T cell production of IFN γ and IL17 and before proceeding to the staining protocol, cells were stimulated with 25 ng/ml phorbol 12-myristate 13-acetate (PMA) and 1 μ g/ml ionomycin in

RPMI_{complete} for at least 6 hours at 37°C and 5% CO₂ in round bottom 96 well plates. After the first hour of incubation, cytokine secretion was blocked adding Golgi Stop protein transport inhibitor (monensin) 1:1000 to the medium.

After stimulation with PMA and ionomycin, cell surface molecules were detected as described in section 2.4.8.1 and using FACS buffer with Golgi Stop diluted 1:1000. All FACS extra and intracellular stainings were performed under the hood in sterile conditions to avoid contamination of the stock antibodies.

For intracellular staining of cytokines, cell suspensions were fixed with Cytofix/Cytoperm for 1 hour, washed twice with Perm/Wash buffer diluted 1:10 in bidistilled H₂O and incubated with anti-IL17 and anti-IFN γ antibodies diluted 1:50 in Perm/Wash buffer in the dark for 30 minutes at 4°C. 50 μ l of staining solution was added per well.

2.4.8.4 Flow cytometry analysis

Cell suspensions were centrifuged and washed twice. Flow cytometry analysis was performed using a FACS Canto II device able to detect an eight color panel using FITC, PE, PerCP-Cy5.5, PE-Cy7, APC, APC-Cy7, AmCyan, and Pacific Blue fluorophores. Different combinations of the eight fluorophore labeled antibodies (listed in table 12) were used for FACS stainings. BD FACSDiva Software 6.1.2 was used to preview and record data from all samples.

2.4.9 Histology

2.4.9.1 Preparation of mouse tissue for immunohistochemistry

CD11c^{tdTomato}, CX3CR1^{eGFP} and double transgenic CD11c^{tdTomato} CX3CR1^{eGFP} mice were sacrificed by cervical dislocation after anesthesia and transcardially perfused with PBS. Small intestines were dissected leaving approximately 0.5 cm separation below the stomach as described in section 2.4.7. The mesenteric fat and blood vessels were carefully removed and the intestinal content was flushed with cold PBS using a 10 ml syringe and 18G needle.

The small intestine samples were fixed overnight in 4% PFA and incubated 1 day in PBS, loaded in cassettes, dehydrated and immersed in paraffin using an Excelsior AS automated tissue processor. Tissues were embedded in paraffin blocks using a MEDITE TES Valida paraffin embedding system and cut in 2 to 4 μm sections using a Leica SM2000 R sliding microtome.

2.4.9.2 Deparaffinization and dehydration of small intestine sections

Before further immunohistochemistry methods, all sections were heated in an oven at paraffin melting point (56-58°C) for at least 1 hour, gradually deparaffinized in xylene and rehydrated in graded isopropyl alcohol series as shown in table 21.

| Reagent | Repetitions | Function |
|--------------------------|---------------|-------------------|
| Xylene | 4 x 5 minutes | Deparaffinization |
| Isopropyl alcohol/Xylene | 1 x 2 minutes | |
| Isopropyl alcohol (100%) | 2 x 3 minutes | Rehydration |
| Isopropyl alcohol (90%) | 1 x 3 minutes | |
| Isopropyl alcohol (70%) | 1 x 3 minutes | |
| Isopropyl alcohol (50%) | 1 x 3 minutes | |
| Distilled water to rinse | 30 seconds | |

Table 21. Deparaffinization and rehydration series of paraffin embedded sections. Before proceeding to any immunostaining protocol all slides were deparaffinized and rehydrated.

2.4.9.3 Fluorescent immunohistochemistry

CD11c^{tdTomato} CX3CR1^{eGFP} transgenic mice were used to visualize CD11c⁺ and CX3CR1⁺ cells in the small intestines. To enhance the fluorescence intensity, immunohistochemistry with anti-GFP and anti-RFP antibodies was performed.

To avoid antigen masking after PFA fixation, citrate buffer antigen retrieval was performed before the immunohistochemical staining^{268,269}. The citrate based solution is designed to break the protein cross-links, hence unmask the antigens and epitopes in paraffin embedded tissue sections, enhancing the intensity of antibodies.

The sections were incubated in preheated sodium citrate buffer 10 mM, pH=6 in a steamer at 95-100°C for 30 minutes. If not stated otherwise, the next part of the protocol was performed at room temperature and the washing steps were repeated 3 times for 5 minutes using PBS.

After washing, the slides were incubated with 3% hydrogen peroxidase solution for 60 minutes in order to block endogenous peroxidase activity, 1% triton for 20 minutes and 10% goat serum for 30 minutes to reduce nonspecific hydrophobic binding. Washing steps were performed between the incubations.

All sections were washed and incubated overnight with a polyclonal anti-GFP primary antibody (#PABG1-100) diluted 1:2000 (table 10). To enhance the immunohistochemical detection of eGFP, tyramide signal amplification was performed on paraffin embedded sections²⁷⁰ using the Tyramide SuperBoost Alexa Fluor 488 kit (table 4). This kit is based on the activation of Alexa Fluor tyramids by horseradish peroxidase (HRP), resulting in the formation of tyramide radicals that covalently bind to tyrosine residues in close proximity of the HRP.

The Tyramide SuperBoost Alexa Fluor 488 kit was used according to the manufacturer instructions. Briefly, the next day the slides were washed and incubated with a biotinylated anti-rabbit IgG antibody (#111-065-144) diluted 1:500 (table 11) for 1 hour. After washing, the slides were developed in tyramide working solution and the reaction was monitored using a fluorescence microscope. After 10 minutes the reaction was stopped using the Reaction Stop Reagent.

Subsequently, the slides were washed and incubated overnight with a polyclonal anti-RFP antibody (#600-401-379S) diluted 1:100 (table 10) at 4°C. The next day, the sections were washed and stained with a Cy3 conjugated anti-rabbit IgG antibody (#111-165-144) diluted 1:100 (table 11) for 2 hours in darkness.

After washing, nuclei were counterstained with DAPI (1:10 000 in PBS) for 10 minutes. Slides were washed again, rinsed once in distilled water and mounted using fluorescence mounting medium.

2.4.10 CYP1A1 expression analysis

In order to analyze expression of the AhR targeted gene CYP1A1, dendritic cells were isolated from the spleens of AhR^{fl/+} CD11c^{Cre+} R26^{eYFP} and AhR^{fl/-} CD11c^{Cre+} R26^{eYFP} transgenic mice (depicted in figure 3). Single cell suspensions were prepared and counted using a Neubauer chamber as described in sections 2.4.5 and 2.4.6.

2.4.10.1 Purification of dendritic cells

Dendritic cells were purified by depletion of non-target cells (negative selection) using magnetic activated cell sorting (MACS). Single cell suspensions were centrifuged for 10 minutes at 300 x g and 4°C and resuspended in 10 ml of MACS buffer. Cells were flushed through a 40 µm cell strainer and then rinsed with an equal volume of MACS buffer passed through the filter.

The Pan Dendritic Cell Isolation Kit (mouse), LS columns and the QuadroMACS separator were used according to the manufacturer's instructions. After MACS separation, cells were resuspended in 200 µl of FACS buffer and YFP⁺ DC were further purified using a BD FACS Aria II cell sorter.

2.4.10.2 Quantitative real time PCR analysis of CYP1A1 expression

AhR deficient (AhR^{fl/-} CD11c^{Cre+} R26^{eYFP}) and AhR competent (AhR^{fl/+} CD11c^{Cre+} R26^{eYFP}) DC were cultured in round bottom 96 well plates at a concentration of 250 000 cells per well and were *ex vivo* stimulated with 250 nM of FICZ, high affinity agonist of AhR, for 24 hours.

After FICZ stimulation, the supernatant was removed and the DC were lysed in QIAzol Lysis Reagent. Subsequently, RNA was isolated using the NucleoSpin RNA XS Kit following the manufacturer's protocol for cultured cells and transcribed into cDNA using the High-Capacity RNA-to-cDNA Kit according to the instructions provided.

Quantitative PCR was performed in the iQ5 Real Time PCR Detection System using the qPCR Core Kit obtained from Eurogentec. The following FAM labeled primers/probes (TaqMan Gene Expression Assays) were selected to be intron spanning from Life Technologies: GAPDH (Mm99999915 g1) and CYP1A1 (Mm00487218 m1).

2.4.11 B16F10 melanoma cell culture and passaging

B16F10 melanoma cells^{271,272} were cultured in 75 cm cell culture flasks using RPMI_{complete}. Cultures were routinely split (1:10) every second to third day when confluence was reached. For cell passaging, the medium was discarded and non-adherent cells were removed by washing with 10 ml PBS before cell dissociation. 1.5 ml of prewarmed 0.01% trypsin solution in PBS was added and cells were incubated at 37°C for 5-7 minutes to ensure cell detachment.

To inactivate the trypsin enzymatic action, 8.5 ml 10% FCS containing media (RPMI_{complete}) were added to the flask. 1/10 of the cell suspension was transferred to a new flask with fresh RPMI_{complete} and maintained in a humidified 37°C, 5% CO₂ incubator until confluent growth and subsequent cell passage or until needed for i.v. inoculation.

2.4.12 *In vivo* lung tumor model

Low density melanoma cell cultures were used for i.v. transfer, which are known to efficiently form lung tumor colonies²⁷³. Approximately $\leq 50\%$ confluent B16F10 melanoma cells were trypsinized as described in 2.4.11 and washed with 10 ml RPMI_{complete}. Cells were counted with a Neubauer chamber as explained in section 2.4.6.

B16F10 cells were resuspended in 0.5% EDTA in PBS and pipetted thoroughly before every injection to avoid cell clumping. Cell suspensions were i.v. injected into the lateral tail veins using 27G needles and 1 ml syringes. All animals were immobilized using a restrainer and the tail veins were dilated under an infrared lamp.

2.4.12.1 Preventive regimen

C57BL/6 and AhR KO mice received Laquinimod 50 mg/kg_{body weight} or vehicle by oral gavage for 14 days. After 3 days of treatment animals were i.v. transferred with 0.5×10^6 B16F10 melanoma cells. At day 11 after tumor inoculation the mice were sacrificed to obtain the lungs.

2.4.12.2 Therapeutic regimen

C57BL/6 were injected in the lateral tail vein with 0.2×10^6 B16F10 melanoma cells. Melanoma cells take 5-10 days to establish and form tumors²⁷⁴. Therefore, treatment with vehicle or Laquinimod 50 mg/kg_{body weight} was initiated at day 11 after i.v. injection once the melanoma cells have established in the lungs. After 1 week of treatment with Laquinimod or water (day 19), all mice were sacrificed and the lungs were isolated.

2.4.12.3 Lung isolation and metastasis quantification

After following the preventive or therapeutic treatment the mice from all experimental groups were sacrificed by a lethal i.p. injection of 14% chloral hydrate. The lungs were carefully dissected, weighted, rinsed with cold PBS and fixed overnight in 4% PFA buffer. Samples were washed with PBS and the number of metastatic colonies were counted under the stereoscopic microscope with an ocular morphometric grid.

2.4.13 Preparation of serum samples for MOG antibody quantification

Blood samples were collected from WT, OSE AhR^{ADC} and OSE AhR^{fl/fl} mice older than 100 days. Mice were restrained using the scruffing technique and 100 to 200 μ L of blood were drawn from the submandibular vein using a 23G needle. After collection, samples were allowed to clot and centrifuged at $300 \times g$ for 10 minutes at 4°C. After centrifugation the resulting supernatant or serum was carefully transferred into a new tube. Serum samples were stored at -20°C until further use.

Anti-MOG antibody titers were determined in the serum samples of OSE AhR^{ADC} and OSE AhR^{fl/fl} mice by an enzyme-linked immunosorbent assay (ELISA). Sera obtained from WT

mice were used as a negative control. For this purpose, sterile 96 well ELISA plates were coated with 100 μ l per well of MOG₁₋₁₂₅ (8 μ g/ml) diluted in PBS at 4°C overnight.

The next part of the assay was performed at RT. If not stated otherwise, the washing steps were repeated 5 times by adding ELISA wash buffer with an 8 channel microplate washer connected to a top bottle dispenser. The plates were dried by tapping the inverted plates against paper towels. 250 μ l of ELISA blocking buffer were added per well and incubated for 2 hours. Plates were washed and 100 μ l of the serum diluted in blocking buffer were added per well. 5-fold serum dilutions (1:500, 1:2500, 1:12500, 1:62500 and 1:312500) were incubated for 1.5 hours at RT.

Once more blots were washed and 100 μ l of polyclonal anti – mouse IgG1 and IgG2A HRP secondary antibodies (1:4000) were added per well and incubated 1 hour in the dark. The last washing step was repeated 7 times and 100 μ l per well of TMB substrate premixed with hydrogen peroxide (H₂O₂) were added. The colorimetric reaction formed a soluble blue product obtained from the TMB oxidation in the presence of the HRP conjugates and H₂O₂. The reaction was stopped with 50 μ l per well of ELISA stop solution to stabilize color development, which turns yellow upon addition. The optical density was measured at 450 nm with 540 nm wavelength as reference using the iMark microplate reader. Samples were run in triplicates used to calculate the average absorbance values at different dilutions and the average background OD was subtracted to each value.

2.4.14 Indol-3-carbinol enriched diet regimen

To investigate the effect of AhR ligands ingested in the diet using a spontaneous EAE model, OSE mice were submitted to a chemically defined diet (E1500) enriched or not with 2 mg/kg of indol-3-carbinol (I3C^{2mg/kg}). At birth, all mothers of OSE mice received free access to the food corresponding to its experimental group.

Animals were randomly assigned to either I3C enriched diet or control group and food was continuously provided. The spontaneous disease development was monitored for 100 days after birth.

3. RESULTS

3.1 Physiological AhR ligands reduce spontaneous CNS autoimmunity by acting on dendritic cells

Multiple endogenous and dietary ligands are known to activate AhR signaling in different immune compartments. An abundant source of indole – based AhR agonists can be found among members of the Brassica genus consumed in the diet; including broccoli, cauliflower, Brussel sprouts and cabbages. Indol-3-carbinol (I3C) is one dietary indole derivative product which is transformed by non-enzymatic acid condensation into AhR agonists. The microbiota in the gut has the ability to convert such precursors (I3C) into immune regulatory metabolites, controlling T cell dependent inflammation; for example in the EAE model^{275,276}.

In order to test the effect of AhR ligands consumed in the diet in the context of autoimmunity and using a spontaneous EAE model, OSE mice were submitted to a chemically defined diet (E1500) supplemented or not with I3C^{2mg/kg}. Animals received the corresponding diet from birth and the EAE incidence was recorded during the first hundred days of life.

Control mice received the same diet without the I3C enrichment. The mothers received matching diets to their pups from the day they gave birth. The pups remained their whole life with the same diet and the mothers were changed back to regular chow after weaning.

3.1.1 Diet supplementation with an AhR ligand suffices to modify the EAE incidence in OSE mice

Adding one AhR ligand precursor to the chemically defined diet composition, the EAE incidence significantly dropped during the first three months of age, when most of the OSE mice spontaneously develop the first symptoms. 35.7% (15/42) of the OSE mice fed with the chemically defined diet spontaneously developed EAE, whereas only 3.1% (1/32) of the mice receiving the I3C enriched diet presented clinical signs (figure 5A).

The OSE mice fed from birth with the supplemented diet count with all necessary elements to mount an effective immune response and are fully susceptible to EAE induction. MOG₃₅₋₅₅ immunized OSE mice under the I3C enriched diet were fully capable of developing EAE within the two following weeks postimmunization (figure 5B).

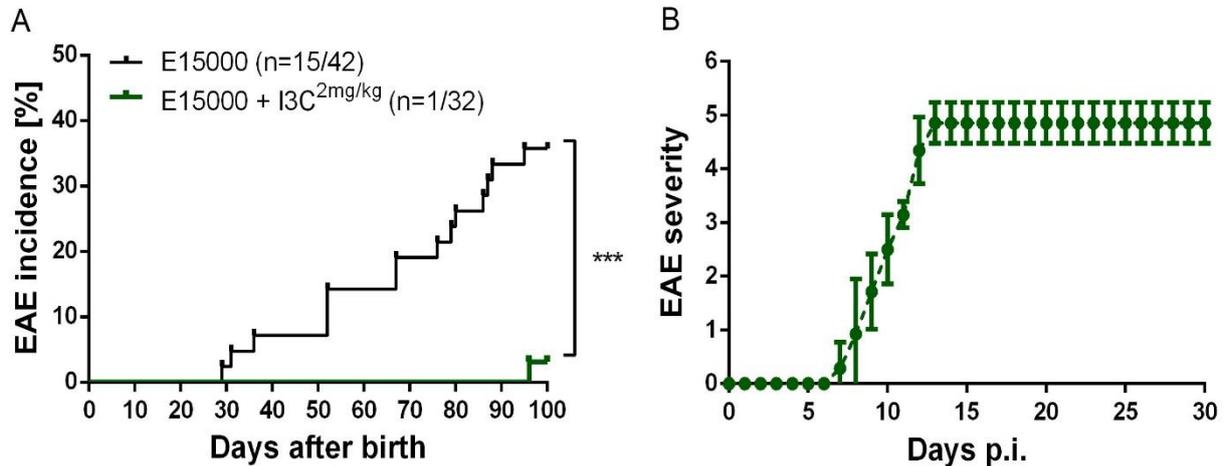

Figure 5. Indol-3-carbinol enriched diet abrogates spontaneous EAE development in OSE mice. (A) EAE incidence curves using the Kaplan-Meier estimator. OSE mice were fed with the chemically defined diet E15000 with or without I3C^{2mg/kg} from birth. Spontaneous EAE development was monitored for 100 days. Comparison of EAE incidence curves by log-rank (Mantel-Cox) test. *** $p=0.0007$. (B) OSE mice fed with the I3C enriched diet are fully susceptible to develop EAE if immunized. OSE mice ($n=7$), which remained healthy for 100 days and were fed with I3C were immunized with MOG₃₅₋₅₅ and the EAE course was monitored for 30 days p.i.

Since the addition of AhR ligands to the diet seemed to suppress EAE development, this work aimed to study which cell types expressing AhR exerted immunoregulatory actions and promoted disease suppression in the EAE model.

3.1.2 AhR deficiency in CD4⁺ T cells and astrocytes does not influence spontaneous EAE in the OSE mouse model

Among immune cells, the AhR is highly expressed in CD4⁺ T (helper) cells and dendritic cells (DC)^{123,128}. In the CNS, it is strongly expressed in astrocytes¹²⁶. The aforementioned three cell populations contribute to the neuroinflammatory disease process in CNS autoimmune diseases at multiple levels^{92,277}. Furthermore, DC and CD4⁺ T cells are important regulators of immune surveillance and host – microbe homeostasis in the intestines via AhR signaling pathway^{137,139}.

In order to study AhR repercussions in a cell specific manner and taking advantage of the Cre-Lox system, AhR was deleted in CD4⁺ T cells (OSE AhR^{ΔCD4}), DC (OSE AhR^{ΔDC}) or astrocytes (OSE AhR^{ΔAstro}) of OSE mice and monitored every other day for EAE symptoms for 100 days. AhR competent controls (OSE AhR^{fl/fl}) did not differ from their OSE AhR^{ΔAstro} and OSE AhR^{ΔCD4} littermates in EAE onset (figure 6A and D), EAE severity course (6B and E) and maximum disease scores (6C and F) respectively.

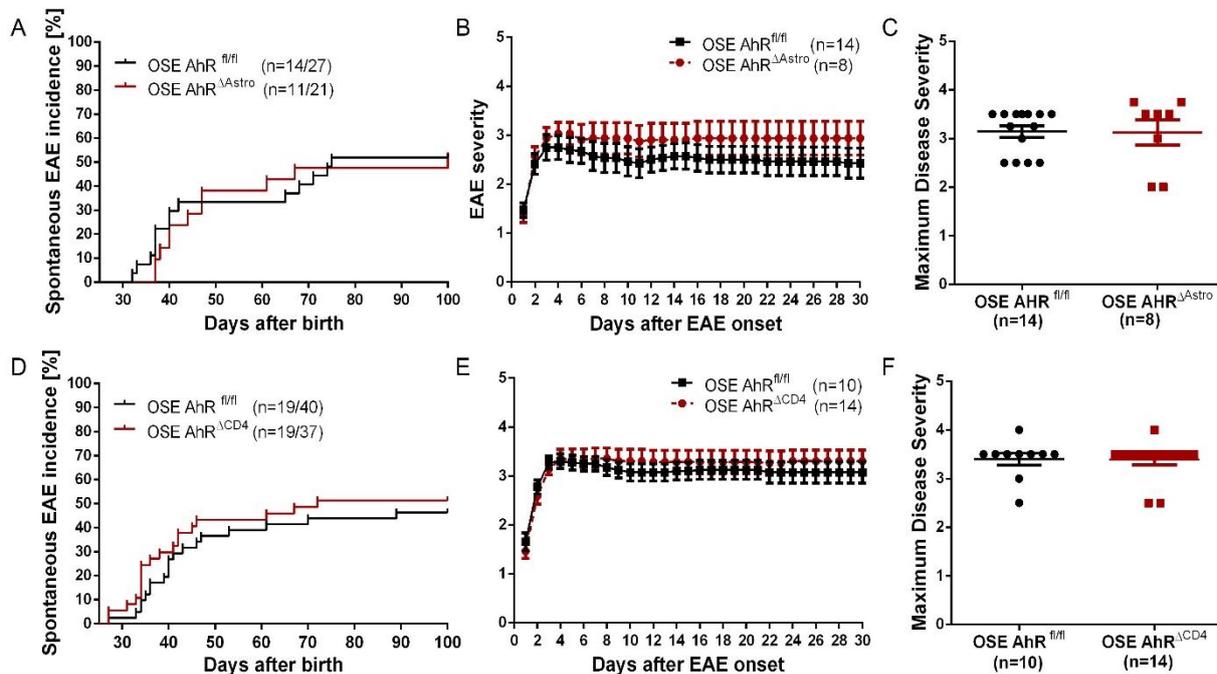

Figure 6. AhR deficiency in CD4⁺ T cells and astrocytes does not influence spontaneous CNS autoimmunity in OSE mice. Kaplan-Meier curves are shown to depict spontaneous EAE incidence and were compared using log-rank (Mantel-Cox) test. EAE severity was monitored for 30 days from the day of EAE onset. Severity curves were analyzed using multiple t tests. Scatter dot plots represent the maximum disease severity, shown as mean \pm SEM and compared using unpaired t test. No difference was found in the EAE incidence, severity and maximum disease severity between OSE AhR^{ΔGFAP} (A, B and C) and OSE AhR^{ΔCD4} (D, E and F) with respect of OSE AhR^{fl/fl} control animals. The number of mice is indicated for each graph.

3.1.3 AhR deficiency in DC significantly increases the incidence of spontaneous EAE

Given the fact that AhR expression in DC plays a central role in their differentiation and function and that DC are the most potent activators of naïve T cells; AhR specific ablation in DC was fundamental to evaluate AhR function in a T cell mediated model such as EAE. AhR deletion in DC doubled the incidence of spontaneous EAE in OSE mice compared to AhR competent littermates (figure 7A, ****p<0.0001).

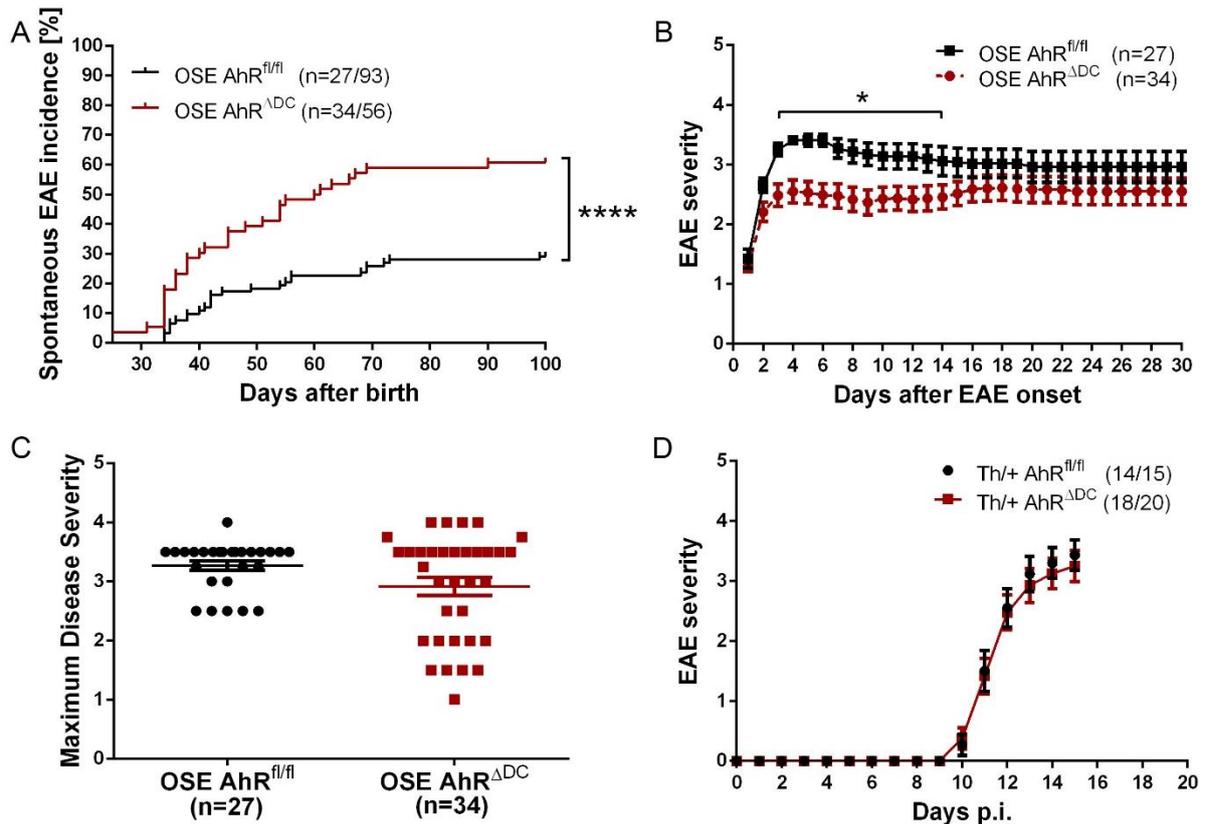

Figure 7. AhR deficiency in DC increases the incidence of spontaneous EAE in OSE mice. (A) Spontaneous EAE incidence curves were compared by log-rank (Mantel-Cox) test. *** $p < 0.001$. (B) EAE disease severity was monitored for 30 days from the day of EAE onset. Severity curves were analyzed using multiple t tests. * $p < 0.05$. (C) The number of mildly affected cases increased in OSE AhR^{ΔDC} mice shown by a greater scatter in the EAE severity compared to OSE AhR^{fl/fl} littermates. Data represented as mean \pm SEM and analyzed by unpaired t test. (D) The EAE severity of Th/+ AhR^{ΔDC} is not influenced if the mice are actively immunized using MOG₁₋₁₂₅. The severity curves were analyzed using multiple t tests and showed no significant difference. The number of mice varies and is indicated in each graph.

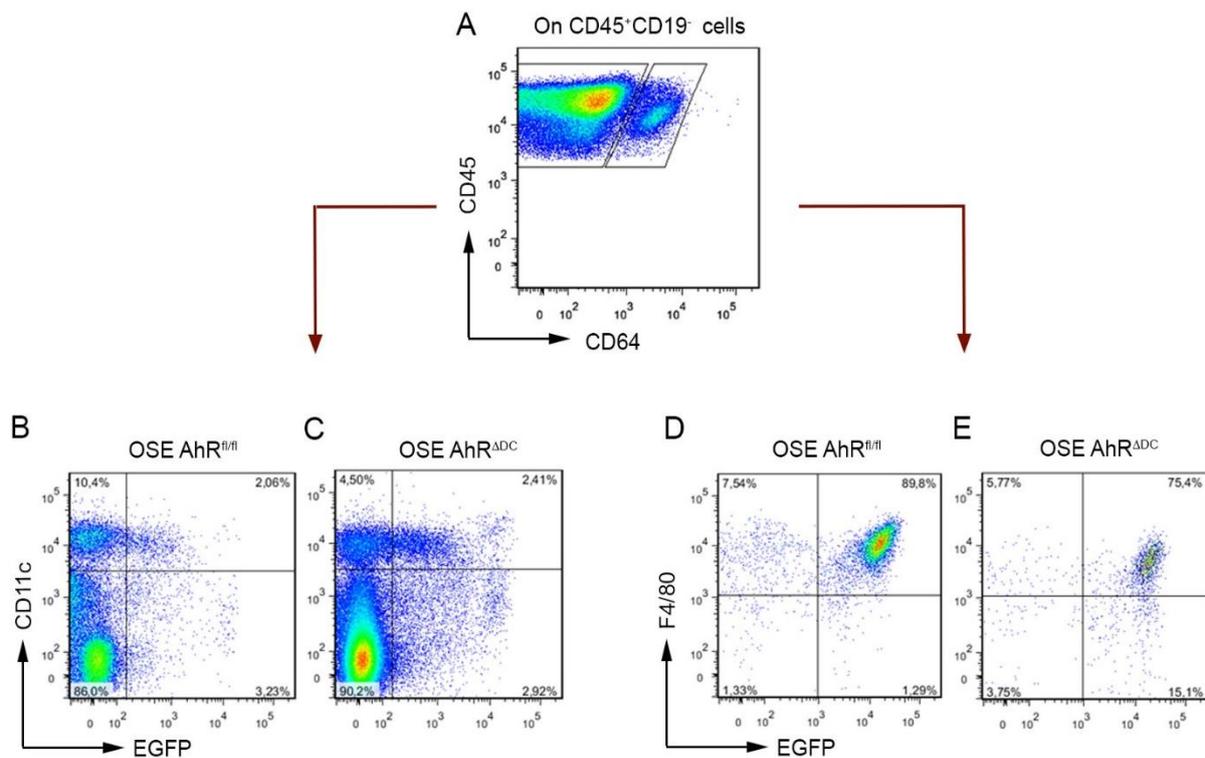

Compared to OSE AhR^{fl/fl} control mice, the OSE AhR^{ΔDC} strain was less severely affected during the first fourteen days after EAE onset (* $p < 0.05$) and was equally sick at later time points (figure 7B). The scattered distribution of the maximum disease severity of OSE AhR^{ΔDC} mice revealed that this group contains more diseased mice that are mildly affected. In comparison, most OSE AhR^{fl/fl} mice presented high scores and a lower dispersion of the maximum EAE severity values (figure 7C).

Besides using a spontaneous EAE model, DC specific AhR deletion was also evaluated in Th/+ mice immunized with MOG₁₋₁₂₅ emulgated in CFA. AhR deficiency in DC did not alter the EAE incidence or severity in the presence of strong immunostimulants such as CFA (figure 7D, $p > 0.05$ using multiple t tests).

3.2 AhR deficiency in DC alters the phenotype of APCs in the lamina propria of OSE mice

In order to explain the higher incidence of OSE AhR^{ΔDC} compared to OSE AhR^{fl/fl} mice the DC and macrophage compartments were analyzed in the LP of OSE mice, where T cell activation might take place in the OSE animal model²⁷⁸.

To discriminate better between DC and macrophages, OSE AhR^{ΔDC} and OSE AhR^{fl/fl} were crossed to CX3CR1^{EGFP} reporter mice. Leukocytes from the small intestine were then isolated from OSE AhR^{ΔDC} CX3CR1^{EGFP/+} and OSE AhR^{fl/fl} CX3CR1^{EGFP/+} animals as described in section 2.4.7 and analyzed *ex vivo* by flow cytometry as explained in 2.4.8.

OSE $AhR^{\Delta DC}$ $CX3CR1^{EGFP/+}$ animals showed a significantly higher percentage of $CD45^+$ $CD11c^+$ $CD64^-$ DC intermediately expressing $CX3CR1$ ($\%CX3CR1^{int}$ DC = $29.4\% \pm 2.8$) compared to OSE $AhR^{fl/fl}$ $CX3CR1^{EGFP/+}$ mice ($18.5\% \pm 1.6$) as shown in figure 9A and B (* $p=0.03$).

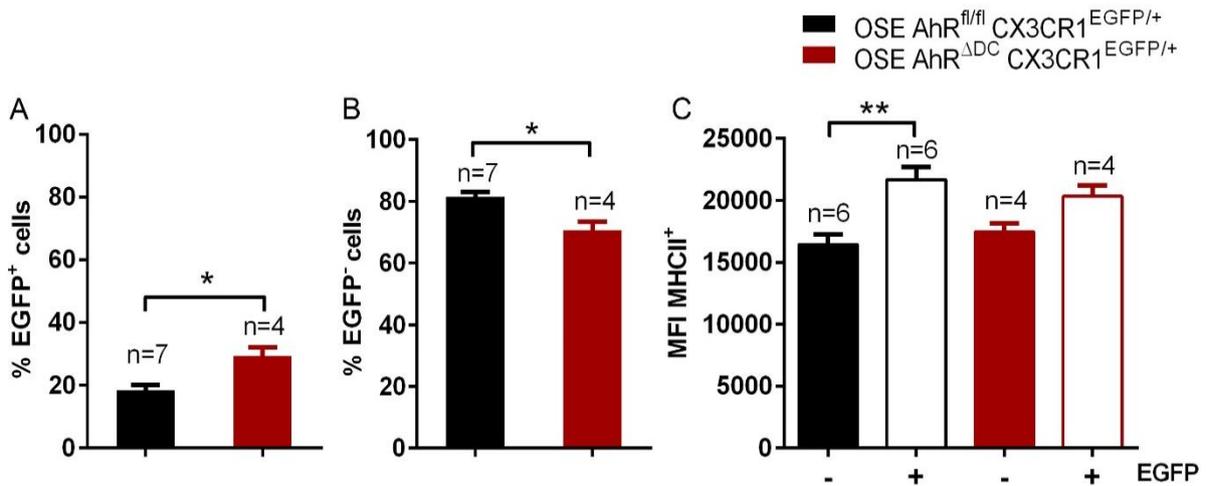

Figure 9. The percentage of $CX3CR1^{int}$ DC increases in OSE $AhR^{\Delta DC}$ $CX3CR1^{EGFP/+}$ mice compared to OSE $AhR^{fl/fl}$ $CX3CR1^{EGFP/+}$ transgenic animals. (A, B) Quantification of $EGFP^+$ and (A) $EGFP^-$ DC cell frequencies. (C) MHCII expression (MFI) on $EGFP^+$ or $EGFP^-$ DC in OSE $AhR^{\Delta DC}$ $CX3CR1^{EGFP/+}$ and OSE $AhR^{fl/fl}$ $CX3CR1^{EGFP/+}$ transgenic animals. Data are presented as mean \pm SEM. Data are pooled from at least four independent experiments. * $p < 0.05$, ** $p < 0.01$, Mann-Whitney U-test.

MHCII expression was analyzed in $CX3CR1^{int}$ and $CX3CR1^-$ $CD45^+$ $CD11c^+$ $CD64^-$ DC of both OSE $AhR^{\Delta DC}$ $CX3CR1^{EGFP/+}$ and OSE $AhR^{fl/fl}$ $CX3CR1^{EGFP/+}$ mice by flow cytometry analysis. Higher MHCII MFI was observed on $CX3CR1^+$ DC compared to $CX3CR1^-$ DC (figure 9C; ** $p=0.0025$ in OSE $AhR^{fl/fl}$ $CX3CR1^{EGFP/+}$ mice), suggesting that $CX3CR1^+$ DC might be better APCs for $CD4^+$ T cells compared to $CX3CR1^-$ DC.

Furthermore, the presence of LP $CX3CR1^+$ and $CX3CR1^-$ DC was detected in paraffin embedded sections of the small intestines of $CD11c^{tdTomato}$ $CX3CR1^{eGFP}$ reporter mice (figure 10). Some DC, which might extend transepithelial dendrites into the lumen of the small intestine were detected by immunohistochemistry (figure 11).

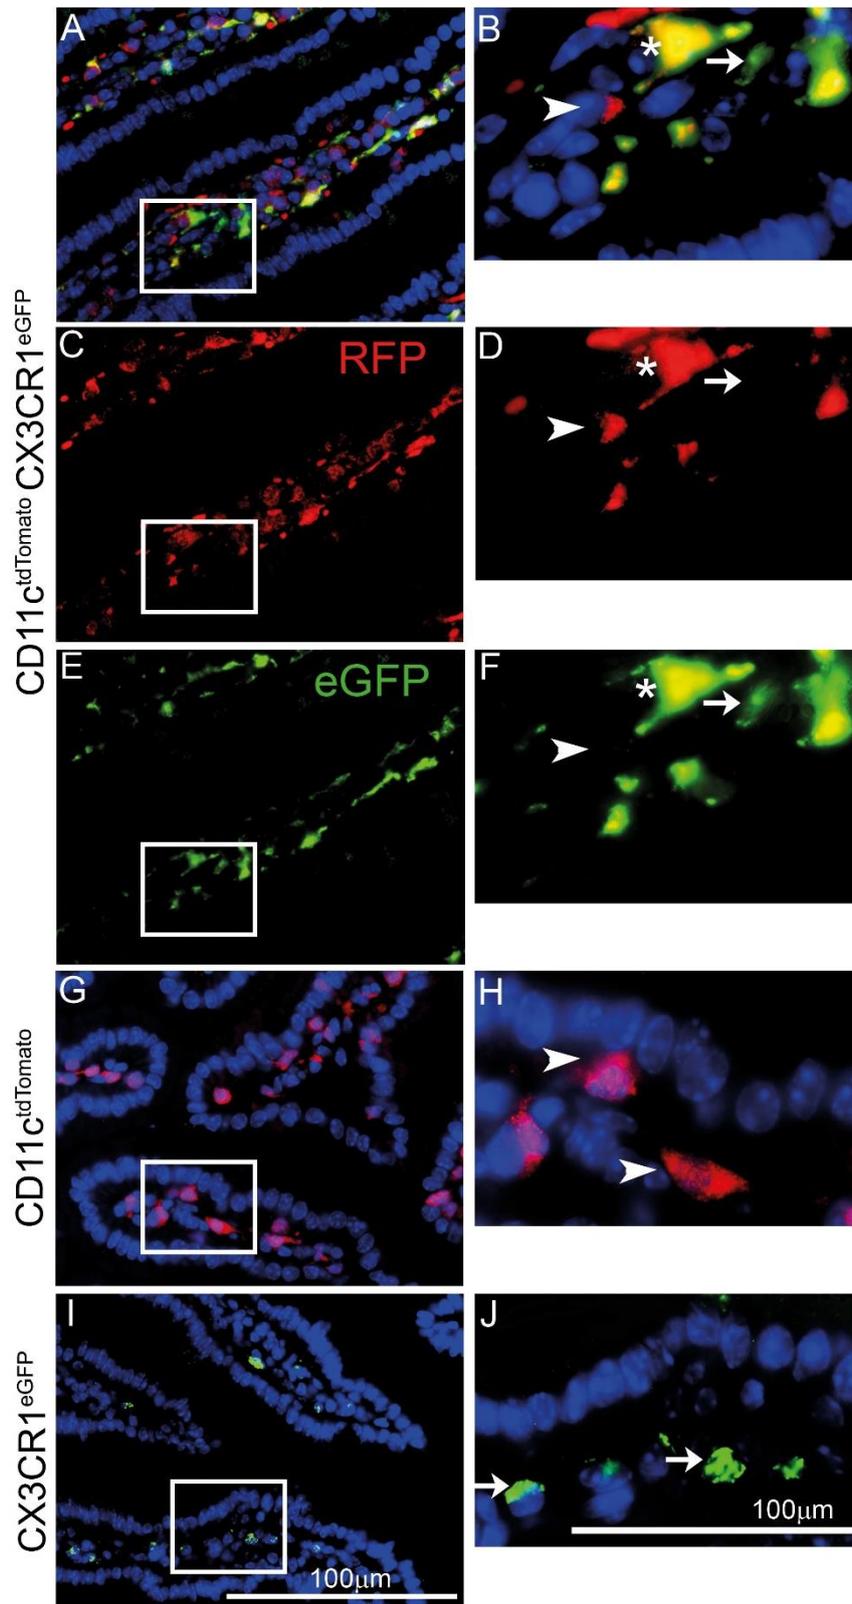

Figure 10. Visualization of intestinal APCs using the $CD11c^{tdTomato} CX3CR1^{eGFP}$ transgenic mice. Mice carrying an eGFP reporter gene under the control of the CX3CR1 promoter and a Cre dependent R26tdTomato gene that labels $CD11c^+$ cells upon Cre recombinase activation. Asterisks indicate $CD11c^+CX3CR1^+$ double positive cells, $CD11c^+$ cells are marked with arrow heads and $CX3CR1^+$ cells with arrows. (A, B) overlay, (C, D) tdTomato $CD11c^+$ cells, red. (E, F) eGFP $CX3CR1^+$ cells, green. (G, H) $CD11c^{tdTomato}$ and (I, J) $CX3CR1^{eGFP}$ single transgenic mice are shown as controls. A, C, E, G and I were acquired using 400x magnification. B, D, F and H are the corresponding insets at 1000x magnification.

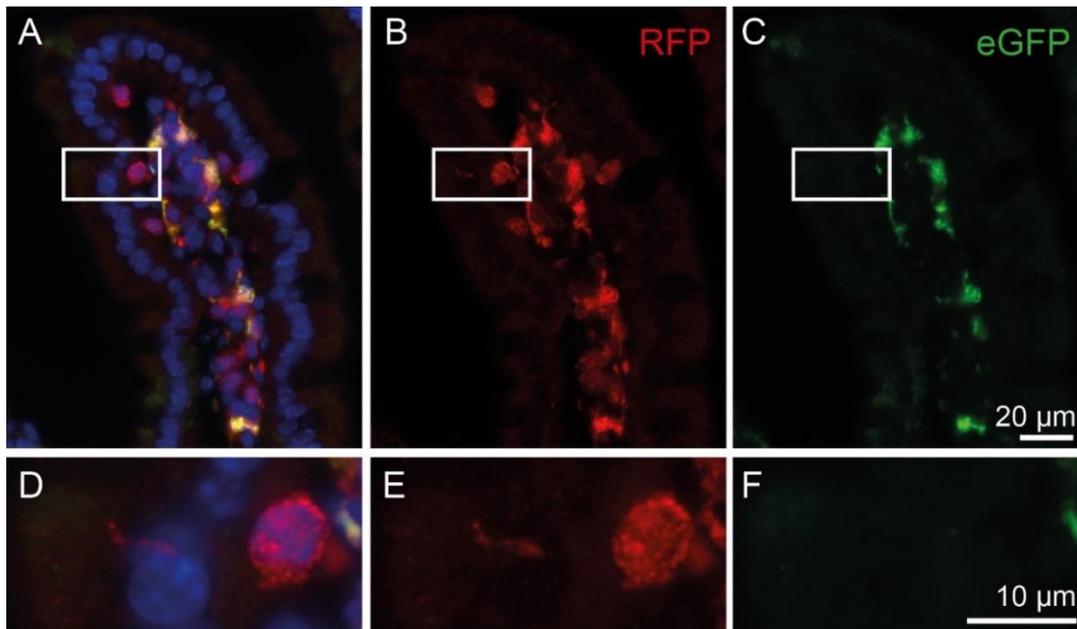

Figure 11. DC might sample luminal antigens by small transepithelial dendrites. Intestinal sections of $CD11c^{tdTomato} CX3CR1^{eGFP}$ reporter mice. (A, D) overlay, (B, E) tdTomato $CD11c^+$ cells, red. (C, F) eGFP $CX3CR1^+$ cells, green. A, B and C were acquired using 400x magnification. D, E and F are the corresponding insets at 1000x magnification.

As shown in figure 8D and E and quantified in figure 12A fewer cells in the lamina propria of OSE $AhR^{\Delta DC} CX3CR1^{EGFP/+}$ mice compared to OSE $AHR^{fl/fl}$ control littermates were bona fide macrophages defined as $CD45^+ CD64^+ F4/80^+ CX3CR1^{high}$. Interestingly, also the macrophage population in OSE $AhR^{\Delta DC} CX3CR1^{EGFP/+}$ compared to the macrophage population in OSE $AHR^{fl/fl}$ mice harbored a more activated phenotype as suggested by downregulation of F4/80 (figure 8D and E) and upregulation of MHCII (figure 12B, MFI=20333 \pm 865 in OSE $AHR^{\Delta DC} CX3CR1^{EGFP/+}$ mice compared to MFI=17467 \pm 706 in control mice).

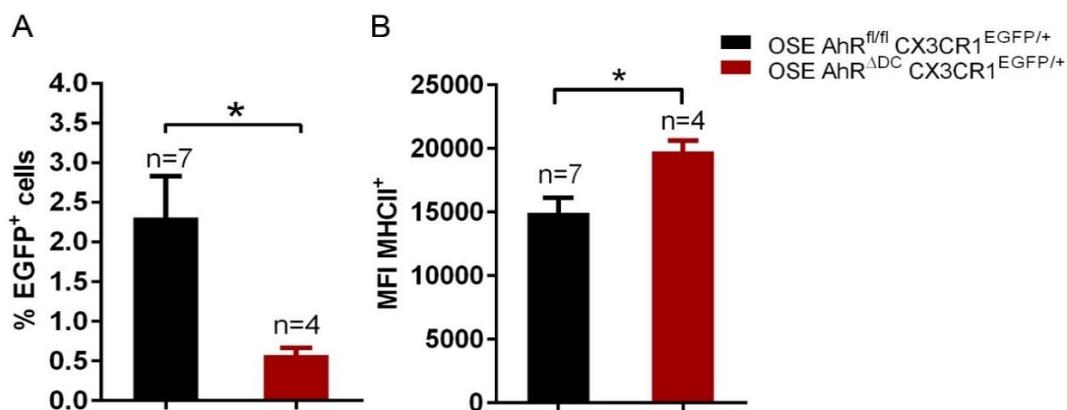

Figure 12. OSE $AhR^{\Delta DC} CX3CR1^{EGFP/+}$ mice showed reduced numbers of intestinal LP macrophages compared to OSE $AhR^{fl/fl} CX3CR1^{EGFP/+}$ control animals. (A) Percentage of $CD64^+ F4/80^+ CX3CR1^{high}$ macrophages among $CD45^+$ leukocytes in the LP of OSE $AhR^{\Delta DC} CX3CR1^{EGFP/+}$ compared to OSE $AhR^{fl/fl} CX3CR1^{EGFP/+}$ mice (B) MHCII MFI of $CD64^+ F4/80^+ CX3CR1^{high}$ LP macrophages. Data are shown as mean \pm SEM. * $p < 0.1$, Mann-Whitney U-test.

To improve the tools to dissect the difference between AhR competent and AhR deficient DC, AhR^{fl/+} CD11c^{Cre+} R26R^{eYFP} and AhR^{fl/-} CD11c^{Cre+} R26R^{eYFP} mice were generated. The former mice have YFP tagged AhR competent DC and the latter YFP tagged AhR deficient DC.

High frequencies of YFP⁺ cells were observed among the DC purified from the spleens of both transgenic strains using MACS separation (figure 13B and C). An upregulation of the AhR reporter gene, CYP1A1, was observed in YFP⁺ AhR competent DC in response to the potent AhR agonist, FICZ, while no changes were observed in YFP⁺ AhR deficient DC.

Thus, these preliminary experiments suggest that the AhR^{fl/+} CD11c^{Cre+} R26R^{eYFP} and AhR^{fl/-} CD11c^{Cre+} R26R^{eYFP} mice might be valuable tools to purify AhR competent and AhR deficient DC *ex vivo* for functional studies.

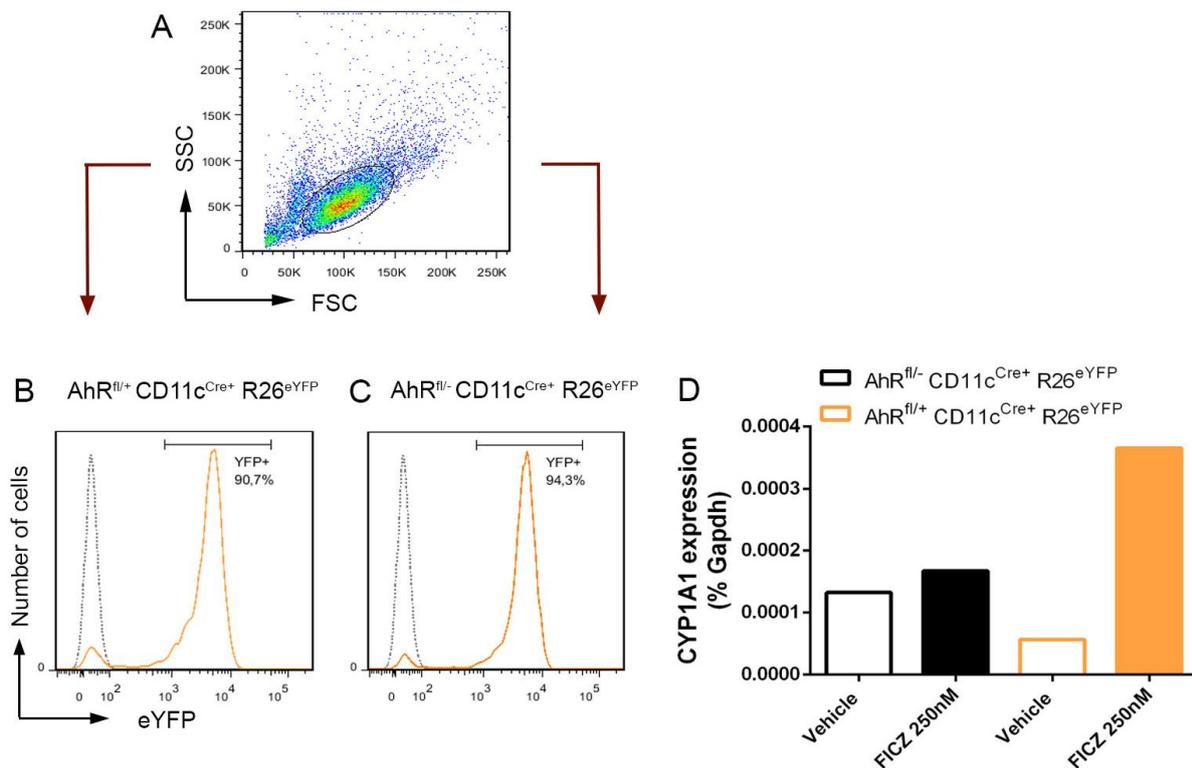

Figure 13. Quantification of CYP1A1 expression in YFP⁺ AhR competent and AhR deficient DC. (A) Representative FACS dot plot of the forward and side scatter of the splenic cells obtained from the transgenic lines. (B) YFP expression of DC purified from AhR^{fl/+} CD11c^{Cre+} R26R^{eYFP} and (C) AhR^{fl/-} CD11c^{Cre+} R26R^{eYFP} mice was analyzed by flow cytometry. (D) Expression of CYP1A1 was quantified by qPCR after FICZ stimulation.

3.2.1 OSE AhR^{ΔDC} mice present increased numbers of IFN γ ⁺ transgenic T cells in the lamina propria of the small intestine

In order to test if the higher percentage of CX3CR1^{int} DC in OSE AhR^{ΔDC} CX3CR1^{EGFP/+} compared to OSE AhR^{fl/fl} CX3CR1^{EGFP/+} mice translates into higher frequencies of cytokine producing CD4⁺ T cells, intestinal leukocytes were isolated from the lamina propria and stimulated with PMA and ionomycin (figure 14B and D). Unstimulated cells were used as controls (14A and C).

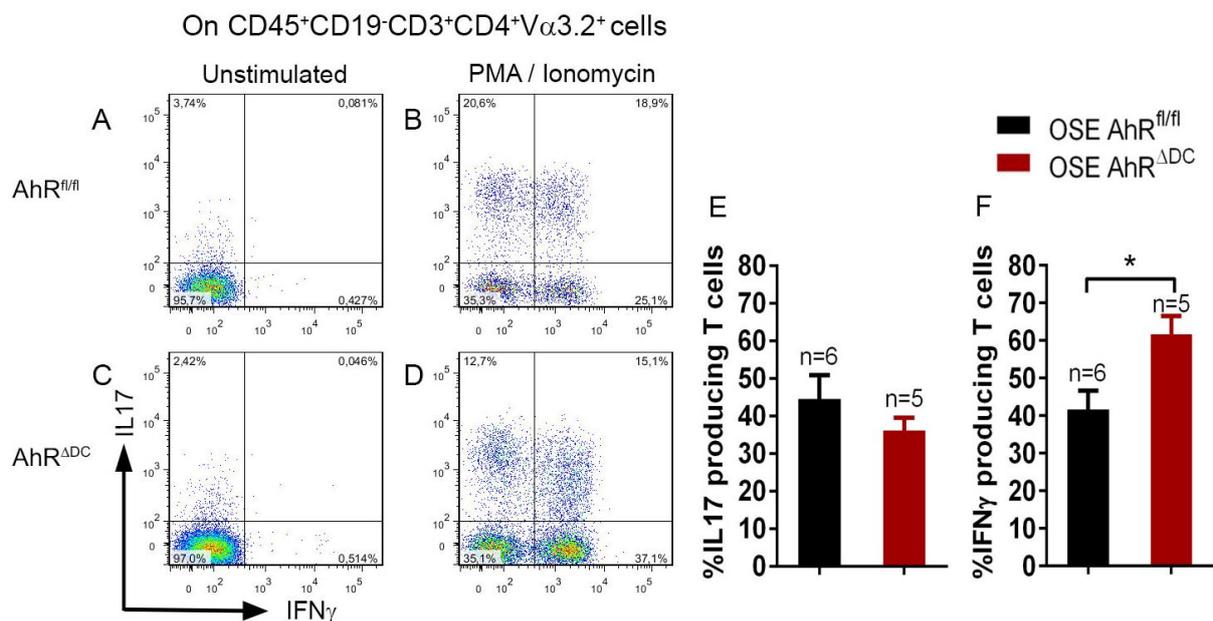

Figure 14. OSE AhR^{ΔDC} mice have significantly higher frequencies of IFN γ producing MOG specific T cells in the lamina propria of the small intestines. (A, B) Representative flow cytometry analysis of intestinal V α 3.2 CD4⁺ T cells obtained from the small intestines of OSE AhR^{fl/fl} control mice and (C, D) OSE AhR^{ΔDC} littermates. (E) The production of IL17 and (F) IFN γ was quantified *ex vivo* by flow cytometry after stimulation with PMA and ionomycin. Data are presented as percentage of the total number of transgenic CD4⁺ T cells and shown as mean \pm SEM. * $p=0.038$, Mann-Whitney U-test.

Cytokine secretion was blocked with Golgi Stop and intracellular detection of IL17 and IFN γ was performed by flow cytometry in V α 3.2⁺ MOG specific TCR transgenic CD4⁺ T cells (described in section 2.4.8.3). A significantly higher frequency of IFN γ (figure 14B, D and F) but not IL17 (figure 14B, D and E) producing transgenic CD4⁺ T cells were detected in response to stimulation with PMA and Ionomycin in OSE AhR^{ΔDC} animals compared to OSE AhR^{fl/fl} control littermates.

3.2.2 OSE AhR^{ADC} mice have significantly higher MOG specific IgG2a antibody titers

IFN γ is known to promote isotype switching to IgG2a production²⁷⁹. Thus, anti-MOG IgG1 and IgG2a antibody titers were quantified in the sera of OSE AhR^{ADC} and OSE AHR^{fl/fl} mice by ELISA performing 5-fold serial dilutions starting at 1:500 as described in section 2.4.13. Significantly higher MOG specific IgG2a (figure 15B) but not IgG1 antibody titers (15A) were found in OSE AhR^{ADC} compared to OSE AHR^{fl/fl} mice at 1:500 (**p=0.008) and 1:2500 dilutions (*p=0.012).

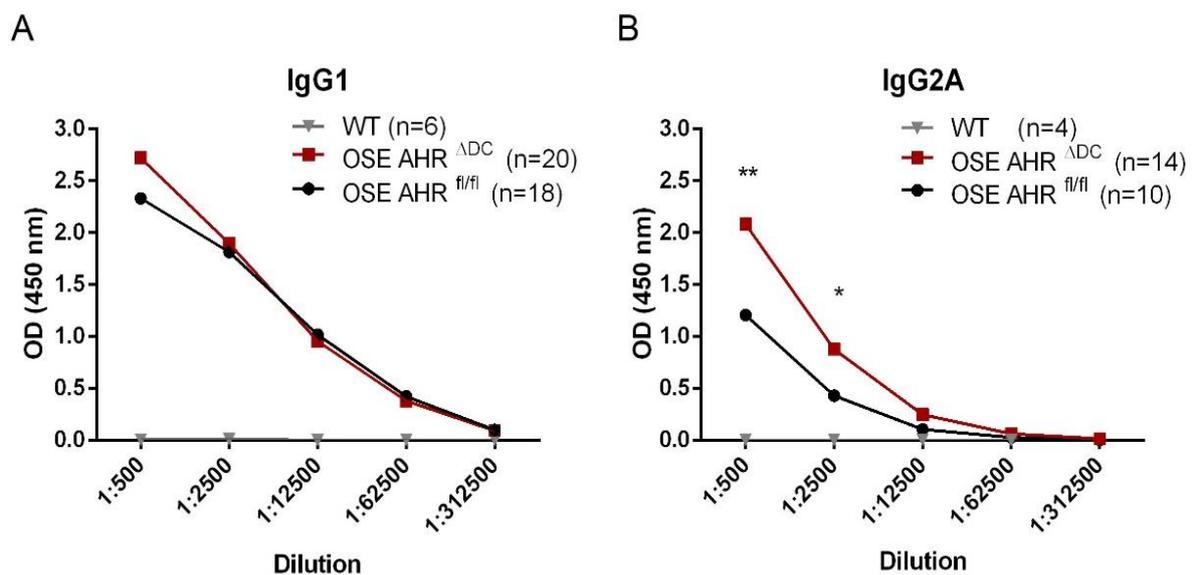

Figure 15. Quantification of MOG specific antibody titers in the sera of OSE AhR^{ADC} and OSE AHR^{fl/fl} mice by ELISA. (A) IgG1 and (B) IgG2A anti-MOG antibody concentrations were measured in the serum of sick OSE AHR^{ADC} and OSE AhR^{fl/fl} mice by indirect ELISA. Serum obtained from healthy WT animals was used as a negative control. Nonspecific binding to BSA was subtracted from all values to calculate the mean absorbance (OD 450 nm) and compared by multiple t tests. * p<0.05, ** p<0.01.

3.3 AhR competent DC are relevant for Laquinimod to suppress EAE

Laquinimod, a quinoline-3-carboxamide derivative, is an oral DMT with moderate efficacy against RRMS²⁸⁰. Previous EAE experiments have suggested that the immunomodulatory properties of Laquinimod might be attributed to its ability of promoting the shift of proinflammatory immune cells towards less immunogenic and more regulatory phenotypes.

Daily oral treatment with Laquinimod from the day of immunization ameliorates or completely abolishes acute EAE development in C57BL/6 mice¹⁸³. In particular, Laquinimod

treatment decreases the immunogenicity of DC, reduces the frequency of proinflammatory IFN γ and IL17 producing T cells and increases the percentage of T $_{regs}$ ¹⁸². In addition, the modulation of nonimmune cells such as astrocytes¹⁸⁹ and endothelial cells¹⁹² might be relevant for Laquinimod's therapeutic efficacy in EAE.

Recent results demonstrated that Laquinimod's ability to suppress EAE is greatly decreased in AhR KO mice^{193,194}. Therefore, the therapeutic efficacy of Laquinimod was evaluated in cell specific AhR deficient mice immunized with MOG₃₅₋₅₅.

3.3.1 Laquinimod's therapeutic effect cannot be attributed to a single AhR competent cell type

EAE was actively induced by MOG₃₅₋₅₅ immunization (as described in section 2.4.2) in AhR Δ CD4, AhR Δ Treg, AhR Δ Astro, AhR Δ DC and AhR^{fl/fl} control mice treated with Laquinimod (25 mg/kg_{body weight}) or vehicle from the day of immunization (section 2.4.4). EAE incidence, onset and maximum disease score were recorded for all transgenic lines in table 22. Animals were handled and scored as explained in 2.4.3 (scoring scale described in table 20).

| | Vehicle | | | Laquinimod | | |
|----------------------|-----------|-------------|---------------|------------|-------------|---------------|
| | Incidence | Max. Score | Disease Onset | Incidence | Max. Score | Disease Onset |
| AhR ^{fl/fl} | 28/41 | 2.92 ± 0.84 | 16.03 ± 4.17 | 3/44 | 2.83 ± 0.58 | 23.00 ± 1.73 |
| AhR Δ DC | 9/10 | 3.06 ± 0.73 | 17.00 ± 4.18 | 7/11 | 2.42 ± 0.53 | 23.00 ± 2.28 |
| AhR Δ Astro | 20/20 | 3.37 ± 0.55 | 15.45 ± 3.16 | 5/20 | 3.25 ± 0.50 | 17,4 ± 1.81 |
| AhR Δ Treg | 12/18 | 3.37 ± 0.70 | 14.33 ± 3.17 | 1/16 | 3 | 22 |
| AhR Δ CD4 | 7/12 | 2 ± 1 | 17.28 ± 5.61 | 2/11 | 2.75 ± 0.35 | 19 ± 7.07 |

Table 22. EAE incidence, maximum disease score and EAE onset. Cell specific AhR deficient mice were immunized with MOG₃₅₋₅₅ and treated with Laquinimod or vehicle. Incidence, maximum disease score of clinically affected mice and EAE onset were assessed for 30 days post immunization and presented as mean ± SD. AhR^{fl/fl} littermates were used as controls.

Vehicle treated AhR^{fl/fl} control mice developed EAE in 68% of the cases (28/41). The EAE incidence in vehicle treated AhR Δ CD4, AhR Δ Treg, AhR Δ DC, AhR Δ Astro varied between 58% (AhR Δ CD4), 67% (AhR Δ Treg), 90% (AhR Δ DC) or 100% (AhR Δ Astro) respectively and was significantly different between vehicle treated AhR Δ Astro and AhR^{fl/fl} controls (figure 18B).

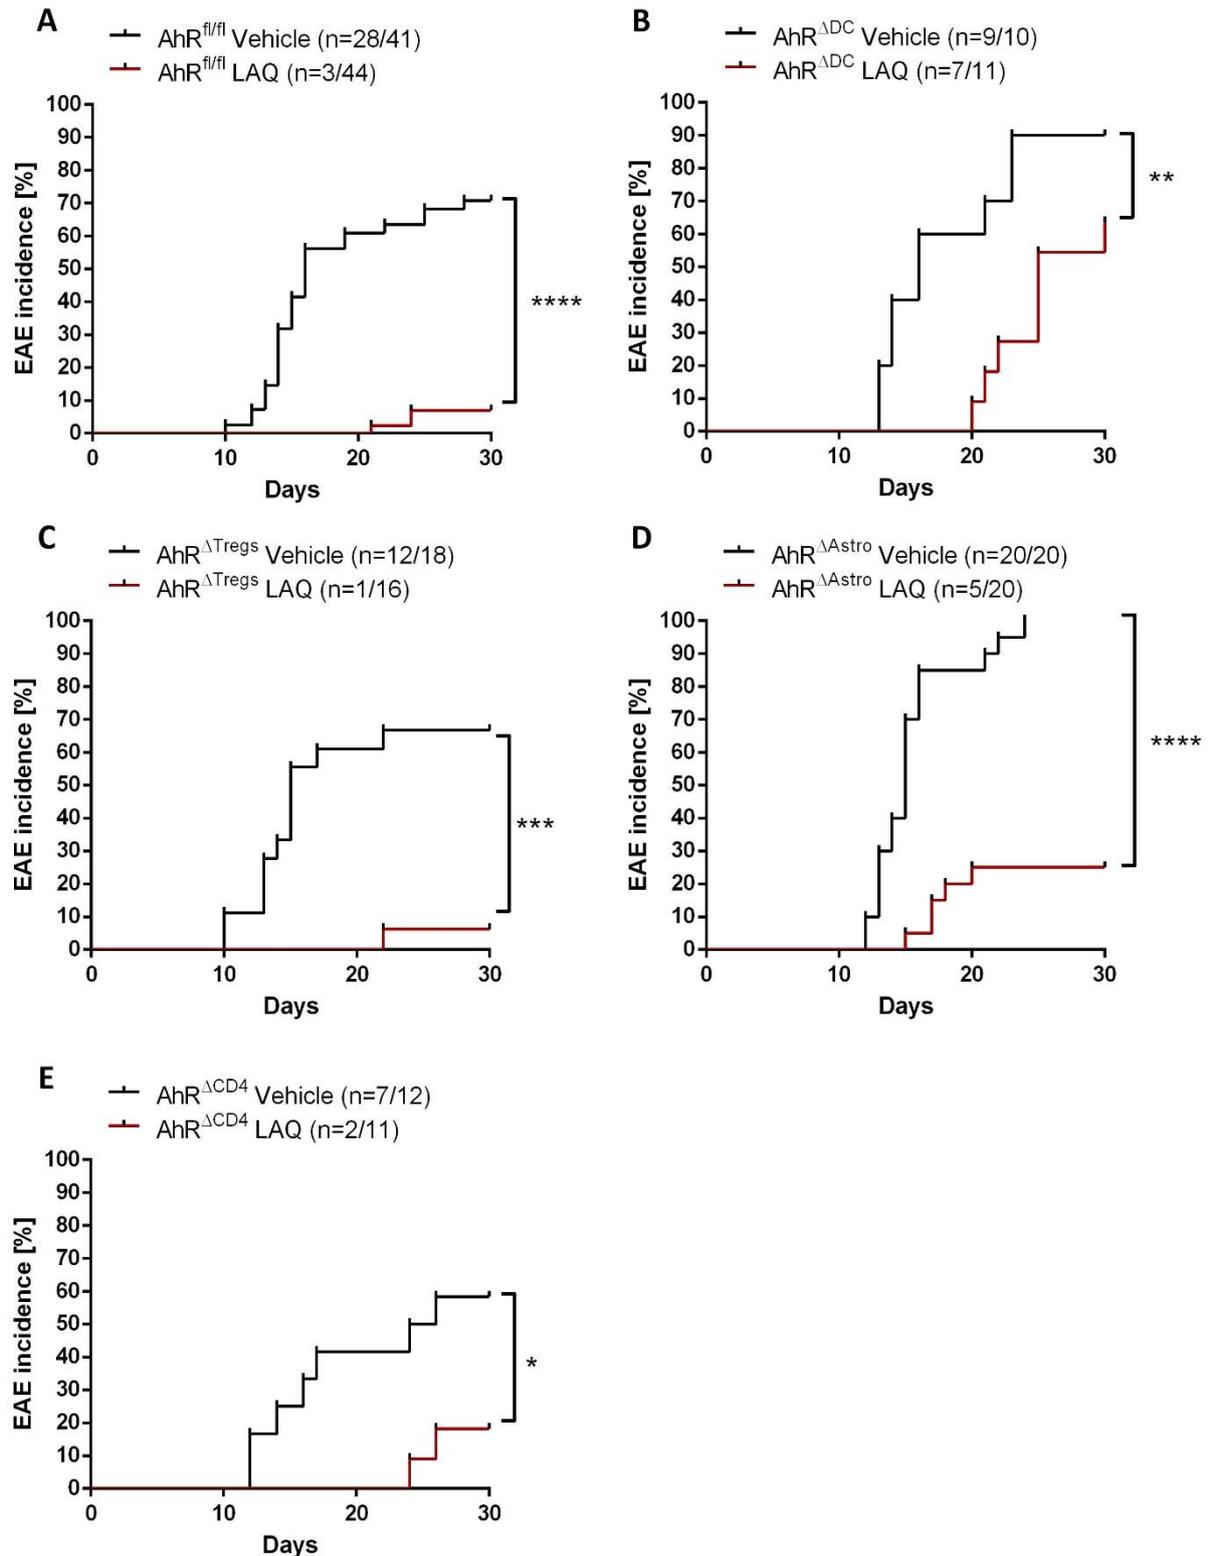

Figure 16. The Laquinimod mediated EAE incidence decrease is less sustained in AhR^{ΔDC} mice. (A) EAE incidence curve of AhR^{fl/fl} control group, (B) AhR^{ΔDC}, (C) AhR^{ΔTreg}, (D) AhR^{ΔAstro} and (E) AhR^{ΔCD4} animals. AhR was deleted in specific cell populations including DC (CD11c^{Cre}), T_{regs} (FoxP3^{Cre}), astrocytes (GFAP^{Cre}) and CD4⁺ T cells (CD4^{Cre}) using the Cre lox system. Mice were daily monitored and treated with Laquinimod (25 mg/kg_{body weight}) or vehicle from the day of immunization to day 30 p.i. Data are shown as mean ± SEM and are representative of three to five independent experiments. *p<0.05, **p<0.01, ***p<0.001, ****p<0.0001, Log-rank (Mantel-Cox) test.

The disease onset was comparable between all vehicle treated cell specific AhR deficient mice and vehicle treated AhR^{fl/fl} controls. The maximum disease scores of the affected animals were slightly higher in mice with AhR deficiency in astrocytes and T_{regs}.

Laquinimod administration delayed the development of EAE symptoms and decreased the EAE incidence in AhR^{fl/fl} control animals and in all cell specific AhR deficient mice compared to littermates treated with water. However, this protective effect was less sustained in AhR^{ΔAstro} (figure 16D) and particularly in AhR^{ΔDC} mice (figure 16B). In descending order, 64% of AhR^{ΔDC}, 25% of AhR^{ΔAstro}, 18% of AhR^{ΔCD4} and 6% of AhR^{ΔTreg} mice developed disease if treated with laquinimod compared to 6.8% of mice in AhR^{fl/fl} controls.

3.3.2 AhR competent DC contribute to Laquinimod's protection against EAE

Laquinimod significantly protected AhR^{ΔDC} mice against EAE induced by active immunization evidenced by a delayed disease onset (EAE onset of vehicle treated AhR^{ΔDC} mice at day 17 ± 4.18 and EAE onset of Laquinimod treated AhR^{ΔDC} mice at day 23 ± 2.28) and a reduction of the mean maximum score of the clinically affected animals compared to vehicle treated AhR^{ΔDC} mice (vehicle treated = 3.06 ± 0.73 and Laquinimod treated = 2.42 ± 0.53).

Nonetheless, the protective effect of Laquinimod was not as sustained as in Laquinimod treated AhR^{fl/fl} mice (figure 16A and 17A) and a significant number of AhR^{ΔDC} animals developed mild EAE symptoms during the last 10 days of the observation period (figure 16B, 17B and 18G).

Laquinimod was also therapeutically effective in AhR^{ΔAstro} mice (figure 16D and 17D). Of note, vehicle treated AhR^{ΔAstro} mice harbored more severe EAE than vehicle treated AhR^{fl/fl} mice (figure 18B and F). Therefore, the slight increase of unprotected Laquinimod treated AhR^{ΔAstro} mice compared to Laquinimod treated AhR^{fl/fl} mice might reflect an increased susceptibility of AhR^{ΔAstro} mice to develop EAE rather than a necessity of the astrocytic AhR mediating the protective effect of Laquinimod (figure 18D and H).

Laquinimod treatment protected AhR^{ΔCD4} (figure 16E and 17E) and AhR^{ΔTreg} mice (figure 16C and 17C) compared to AhR^{fl/fl} littermates. As shown in table 22, the disease onset

was delayed from day 14.33 ± 3.17 (control group) to 22 in the AhR $^{\Delta Treg}$ Laquinimod treated group and there was a slight reduction of the mean maximum score of the diseased mice (AhR $^{\Delta Treg}$ vehicle treated = 3.37 ± 0.70 and Laquinimod treated = 3).

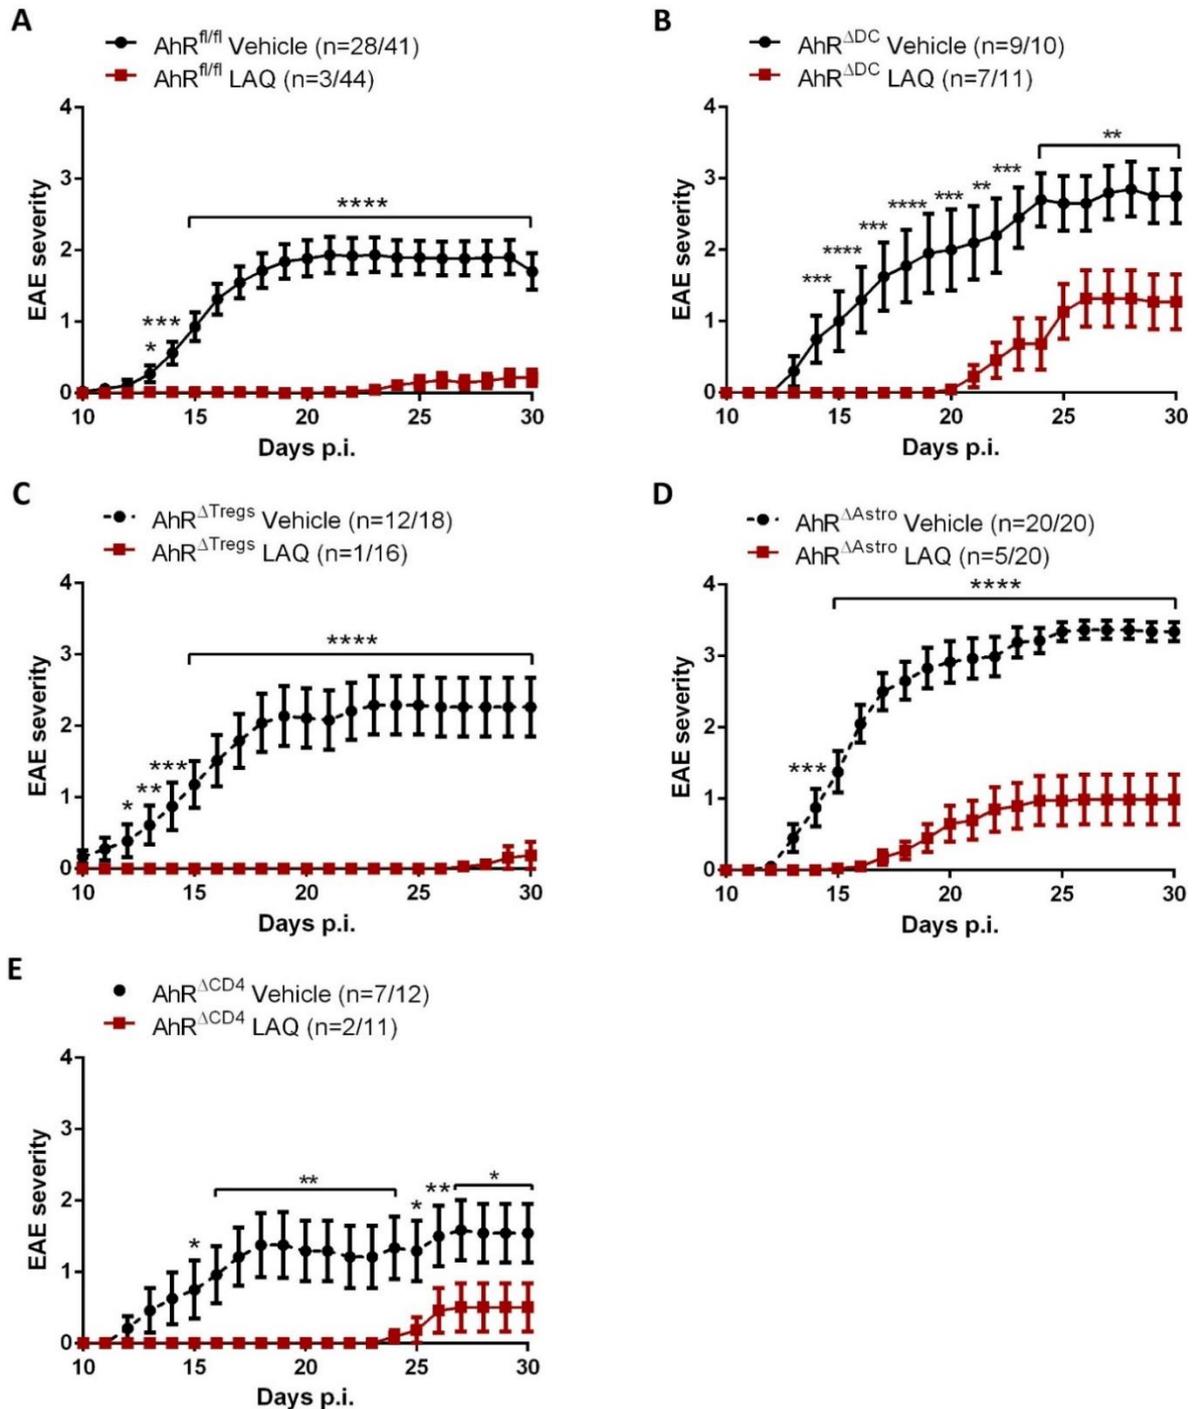

Figure 17. Expression of AhR on DC, T_{regs} and astrocytes is not essential for Laquinimod mediated decrease of EAE severity. Cell specific AhR KO mice were MOG₃₅₋₅₅ immunized and daily treated with Laquinimod (25 mg/kg_{body weight}). Oral administration of the drug or vehicle started on the day of immunization to day 30 p.i. (A) Disease severity curves of AhR^{fl/fl} control mice, (B) AhR^{ΔDC}, (C) AhR^{ΔTreg} and (D) AhR^{ΔAstro} mice. Data are shown as mean \pm SEM and represent three independent experiments. AhR^{fl/fl} mice were used as control group (A). * $p < 0.05$, ** $p < 0.01$, *** $p < 0.001$ and **** $p < 0.0001$. All severity curves were analyzed using multiple t tests.

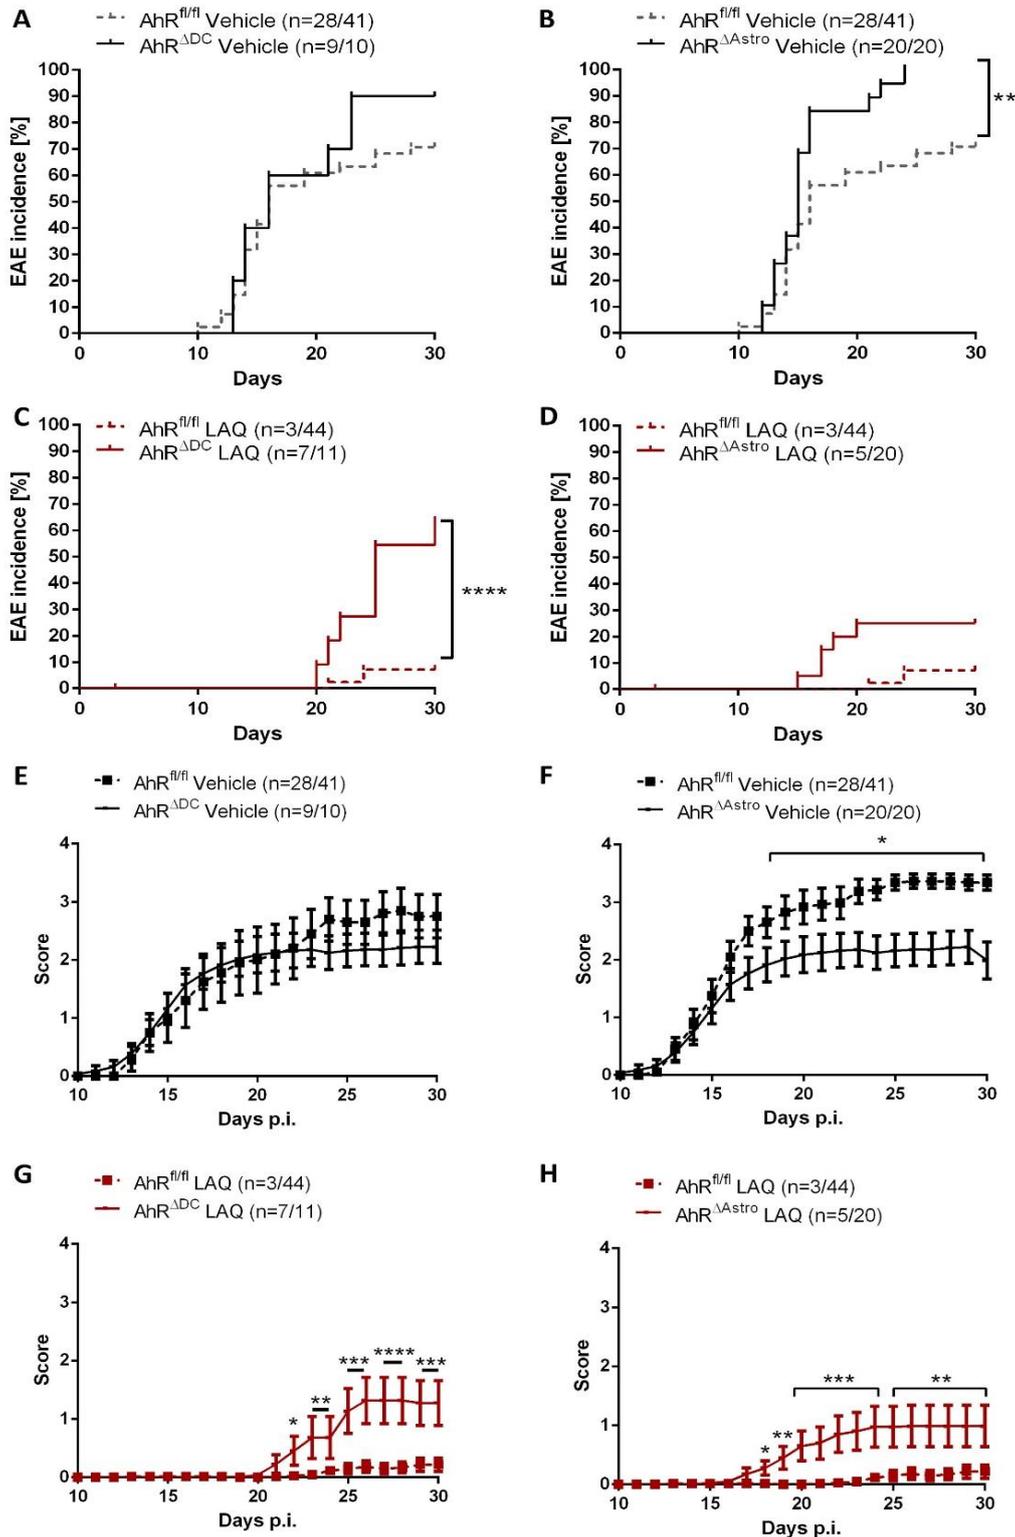

Figure 18. Laquinimod's effect on AhR^{ΔAstro} and AhR^{ΔDC}. (A) EAE incidence curves corresponding to vehicle treated AhR^{ΔDC}, (B) vehicle treated AhR^{ΔAstro}. AhR deficiency in GFAP⁺ but not in CD11c⁺ cells potentiates EAE incidence and does not affect Laquinimod's protective effect. (C) Graphs representing the EAE incidence of Laquinimod treated AhR^{ΔDC} and (D) Laquinimod treated AhR^{ΔAstro}. AhR expression in CD11c⁺ cells is not essential but plays a role in the Laquinimod mediated EAE inhibition, while AhR deficiency in GFAP⁺ cells is not required. (E) EAE severity curves obtained from Laquinimod treated AhR^{ΔDC} and (F) vehicle treated AhR^{ΔAstro}. Data are shown as mean \pm SEM and represent three to four independent experiments. AhR competent (AhR^{fl/fl}) mice were used as control group and are represented with dotted lines. The EAE incidence curves of AhR^{ΔAstro} and AhR^{ΔDC} mice are depicted with solid lines. ** p<0.01, ****p<0.0001, Log-rank (Mantel-Cox) test. The EAE severity curves of AhR^{ΔAstro} and AhR^{ΔDC} mice were analyzed by multiple t tests. * p<0.1, ** p<0.01 and ****p<0.0001.

Laquinimod was able to significantly reduce EAE in all cell specific AhR KO lines compared to vehicle treated littermates. Even though Laquinimod significantly protected AhR^{ADC} mice against EAE compared to AhR^{fl/fl} littermates ($p=0.001$), fewer number of animals were fully protected, arguing for a moderate effect of AhR competent DC mediating the therapeutic efficacy of Laquinimod.

3.3.3 Laquinimod treatment reduces the percentage of CD11c⁺MHCII^{high} DC cells in AhR^{ADC} mice

To date, different mechanisms have been proposed to describe how Laquinimod could suppress EAE. Previous results obtained in C57BL/6 mice suggested that APCs such as CD11c⁺CD11b⁺CD4⁺ DC were reduced and CD11b⁺ cells were modulated towards an anti-inflammatory phenotype^{180,182}.

Ex vivo and *in vivo* experiments displayed a reduction of MHCII, costimulatory molecules (CD80, CD86) and the activation marker CD40 on DC and macrophages after Laquinimod therapy²⁸¹, suggesting that T cell activation and proliferation might be indirectly impaired²⁸². Hence, it was tested if a reduction of CD11c⁺ MHCII^{high} DC can be still observed in Laquinimod treated AhR^{ADC} mice, but also in AhR^{ADC4}, AhR^{AAstro} and AhR^{ATreg} mice.

All Cre lines and AhR^{fl/fl} controls were treated with vehicle or Laquinimod from the day of immunization. At day 10 splenic CD11c⁺ MHCII^{high} DC were evaluated *ex vivo* by flow cytometry as explained in 2.4.8.

All Laquinimod treated mice, including AhR^{ADC} animals, had reduced DC frequencies compared to control littermates. AhR^{ADC} $p=0.036$, AhR^{ATreg} $p=0.009$, AhR^{AAstro}: $p=0.001$, AhR^{ADC4} $p=0.003$, corresponding to figure 19B, C, D and E. AhR^{fl/fl} animals were used as controls (figure 19A, $p=0.002$).

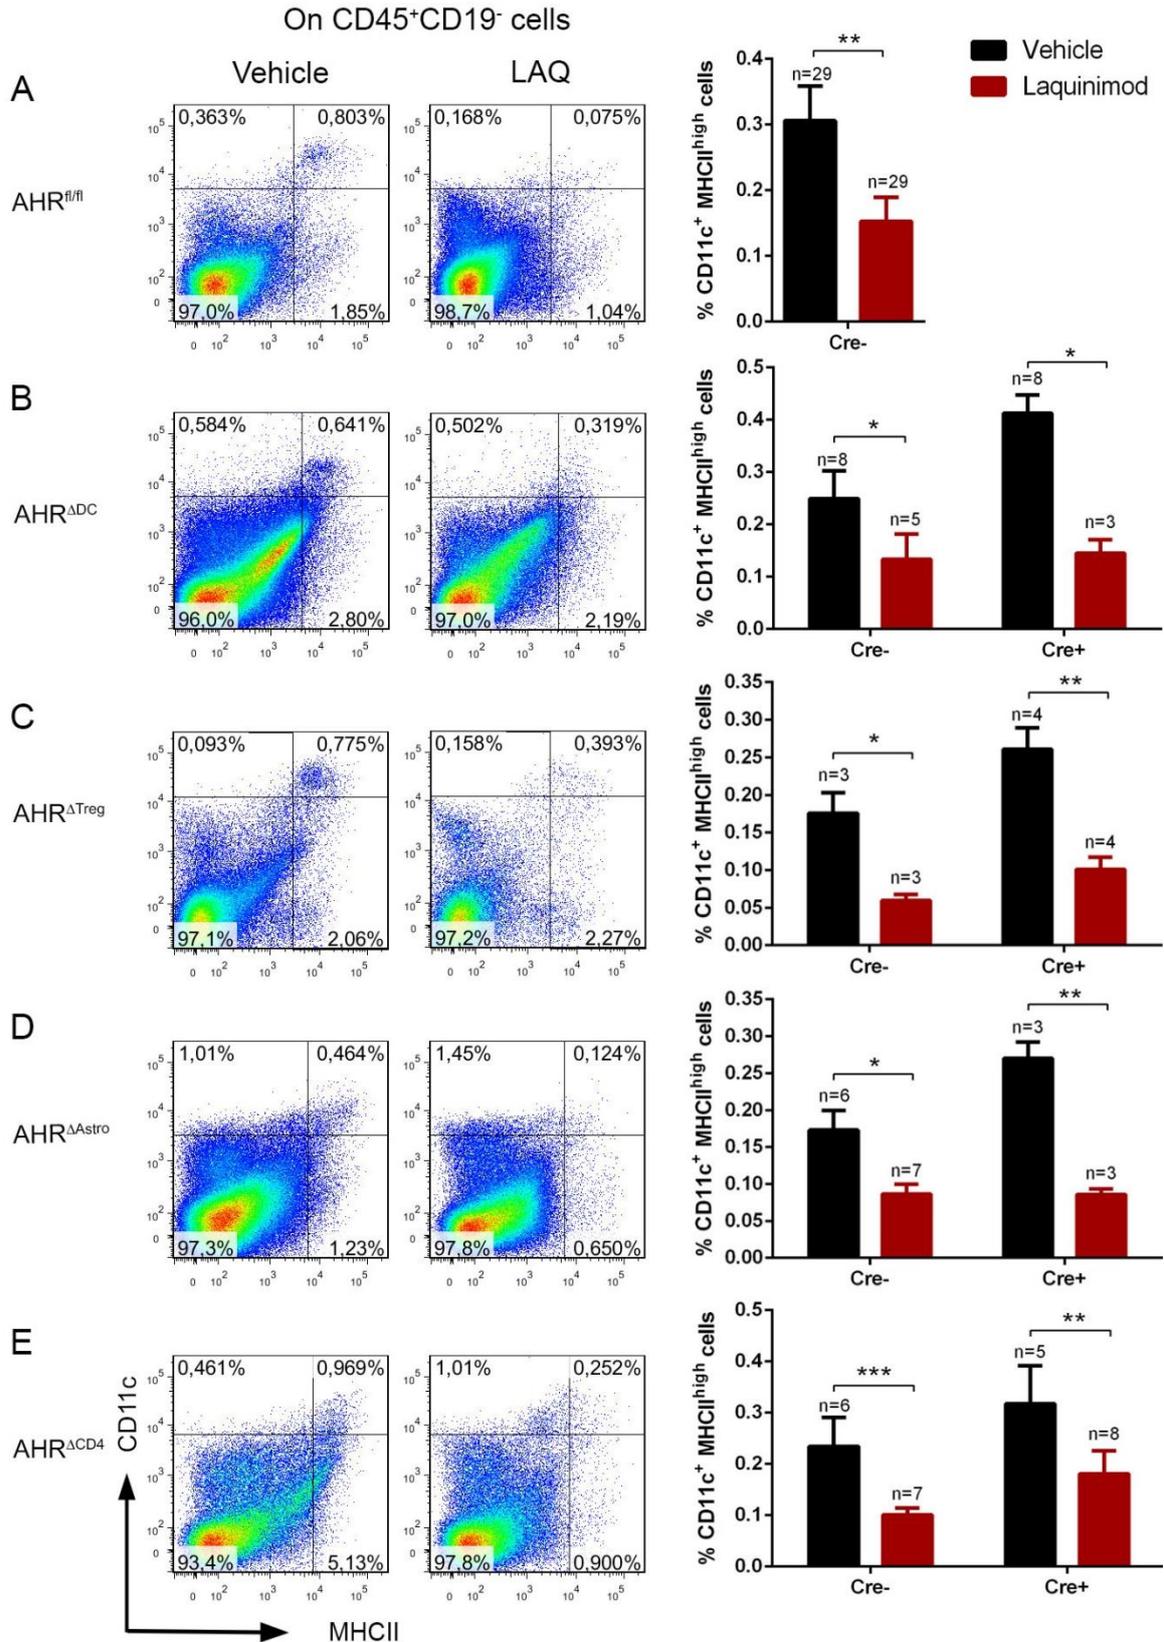

Figure 19. Laquinimod decreases the percentage of CD11c⁺MHCII^{high} DC in AhR^{ADC} mice. Representative dot plots of CD11c and MHCII expression in CD45⁺ CD19⁻ cells of MOG₃₅₋₅₅-immunized (A) AhR^{fl/fl}, (B) AhR^{ADC}, (C) AhR^{ΔTreg}, (D) AhR^{ΔAstro} and (E) AhR^{ΔCD4} mice, which were treated daily with Laquinimod (25 mg/kg_{body weight}) or vehicle from the day of immunization to day 10 p.i. Bar graphs depict the percentage of CD11c⁺ MHCII^{high} cells among total CD45⁺ cells. Data are shown as mean ± SEM. *p < 0.05, **p < 0.01. Mann-Whitney U-test.

3.3.4 Laquinimod requires AhR competent DC to reduce the frequency of Th17 cells

Previous studies performed in Laquinimod treated mice showed that the frequency of proinflammatory Th1 or Th17 CD4⁺ T cells decreases whereas the numbers of T_{regs} increase in the periphery¹⁸² and CNS¹⁹⁶.

In addition, it was demonstrated that AhR is involved in the development of Th17 cells, as well as in the production of IL17 and IL22 cytokines²⁸³. Until now, it remains unclear if Laquinimod directly interacts with T cells or if the shift towards anti-inflammatory T cell populations is indirectly induced by the drug.

Splenocytes were *ex vivo* stimulated with PMA and ionomycin to induce cytokine production. Monensin and brefeldin were added to the cultures in order to block protein transport and to promote cytokine accumulation in the Golgi complex. Intracellular staining of IL17 and IFN γ was analyzed by flow cytometry in splenic CD45⁺CD19⁻CD3⁺CD4⁺ T cells as explained in section 2.4.8.3.

Preventive treatment with Laquinimod significantly decreased 3 to 4-fold the number of IL17 producing CD4⁺ T cells in AhR^{fl/fl} control mice ($p=0.004$), as well as in AhR^{Astro}, (0.002) and AhR^{CD4} ($p=0.004$) corresponding to figure 20A, C and D.

Interestingly, Laquinimod failed to significantly decrease the percentage of IL17 producing CD4⁺ T cells in AhR^{ADC} mice (figure 20B; $p=0.1$), suggesting that the reduction of proinflammatory cytokine producing CD4⁺ T cells is indirectly mediated via AhR competent DC.

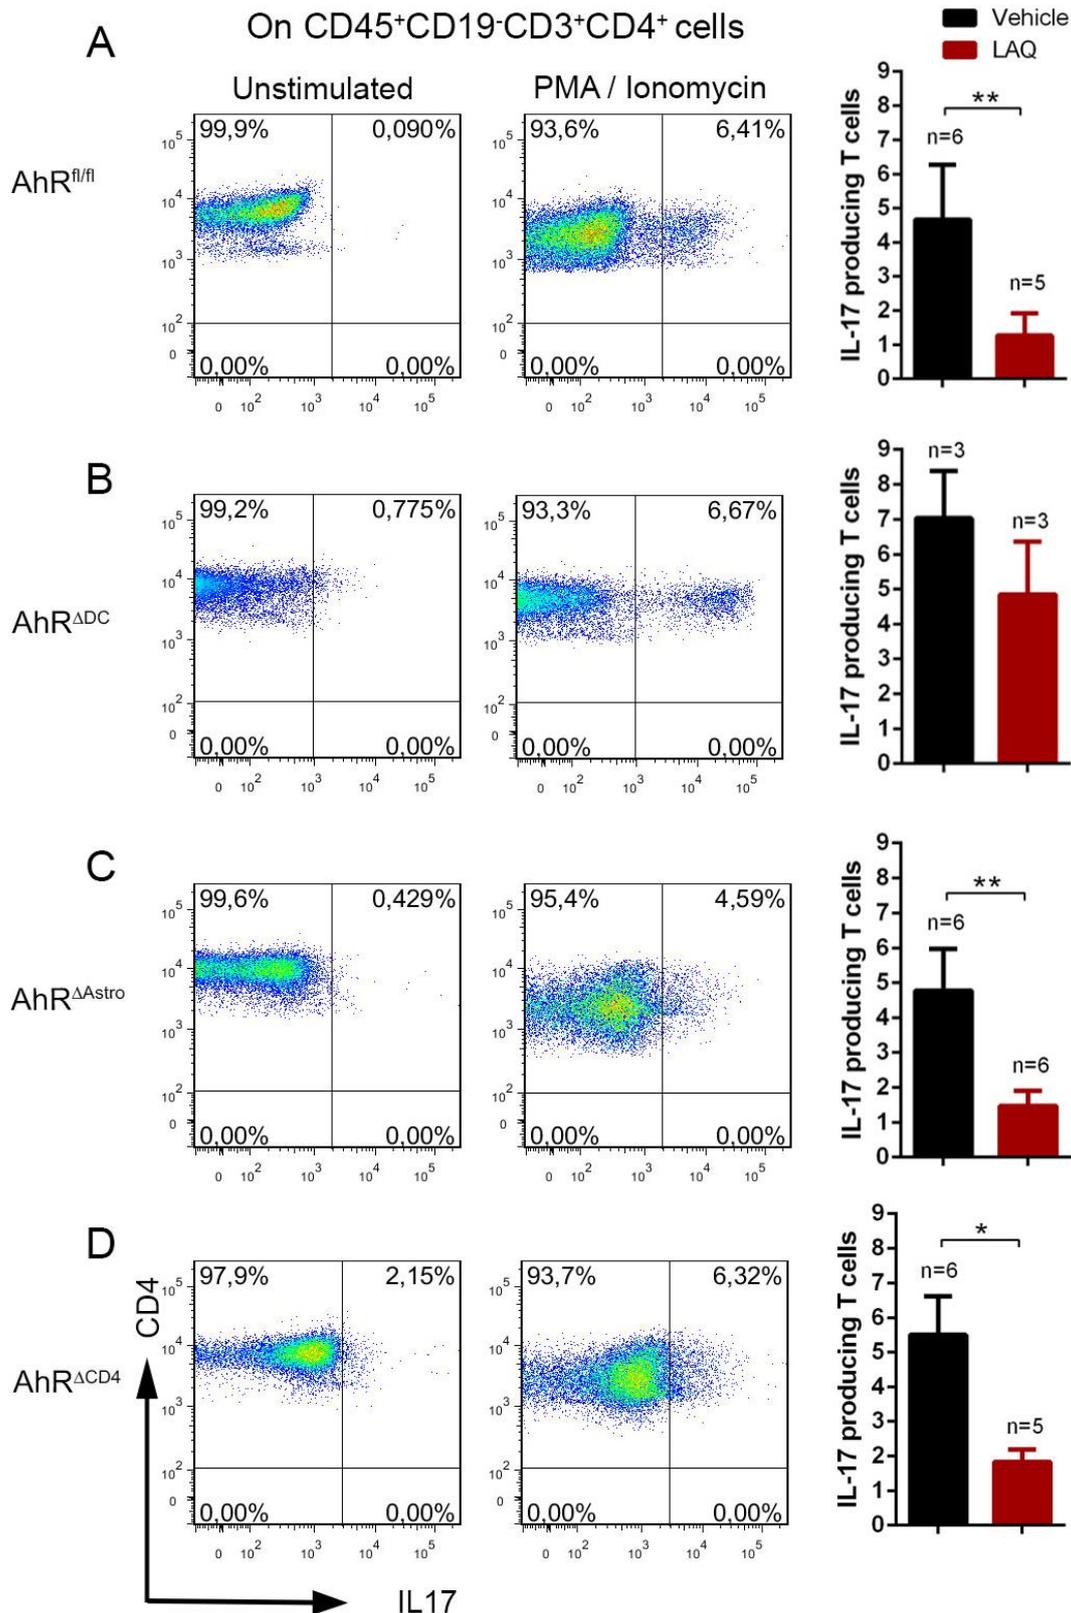

Figure 20. Laquinimod fails to decrease IL17 producing CD4⁺ T cells in AhR^{ΔDC} mice but not in AhR^{ΔCD4} and AhR^{ΔAstro}. Representative flow cytometry analysis of the IL17 producing CD4⁺ T cells isolated from (A) AhR^{fl/fl} control mice, (B) AhR^{ΔDC}, (C) AhR^{ΔAstro} and (D) AhR^{ΔCD4} animals treated daily with Laquinimod (25 mg/kg_{body weight}) or vehicle from the day of immunization to day 10 p.i. IL17 producing T cells were *ex vivo* analyzed by flow cytometry following stimulation with PMA and ionomycin. Data are presented as percentage from the total number of CD4⁺ T cells shown as mean ± SEM and are representative from three different experiments. * p<0.1, **p<0.01, Mann-Whitney U-test.

3.3.5 The AhR-IDO-1 axis does not mediate Laquinimod's protective effect in the EAE model

AhR signaling is required for the expression of indoleamine 2,3 dioxygenase (IDO) in DC, an immunosuppressive enzyme that catabolizes tryptophan into kynurenine^{168,174,284}. Furthermore, the absence of the AhR in bone marrow derived DC skewed the differentiation of naïve T cells towards Th17 and inhibited the differentiation into T_{regs}²⁸⁵.

To assess whether the AhR-IDO-1 signaling loop contributes to the efficacy of Laquinimod to suppress EAE, IDO-1 KO mice and C57BL/6 controls were immunized with MOG₃₅₋₅₅ and treated with vehicle or Laquinimod for 30 days from the day of immunization. Laquinimod inhibited EAE regardless of IDO-1 deletion. IDO-1 competent ($p=0.0003$), as well as IDO-1 KO mice ($p=0.0007$) were fully protected by Laquinimod administration from day 16 onwards compared to vehicle treated animals (figure 21).

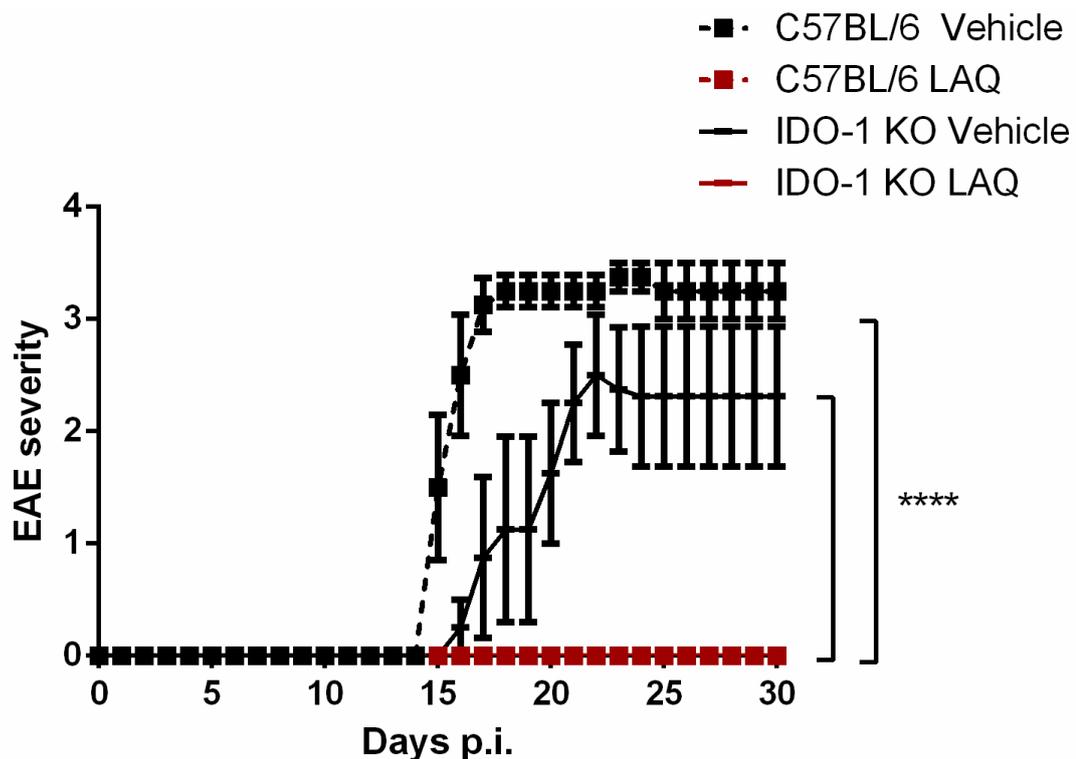

Figure 21. The lack of IDO-1 does not impair Laquinimod's protection against EAE. IDO-1 KO and C57BL/6 mice were immunized with MOG₃₅₋₅₅ and treated daily with vehicle or Laquinimod (25 mg/kg_{body weight}) from the day of immunization to day 30 p.i. Data are shown as mean \pm SEM. **** $p < 0.0001$, Laquinimod versus vehicle treated groups were analyzed by multiple t tests. Control littermates were treated with water as vehicle. $n=10$ for each of the four experimental groups.

3.3.6 Laquinimod increases CD25⁺ FoxP3⁺ T cells in AhR^{ΔCD4} and AhR^{ΔTreg} mice

Laquinimod was previously shown to promote anti-inflammatory conditions by significantly decreasing Th1 and Th17 responses¹⁹⁰ and favoring T_{regs} differentiation and expansion in the CNS¹⁹⁶ and periphery¹⁸².

Different groups have shown that acutely immunized mice with MOG₃₅₋₅₅ and daily treated from the day of immunization with the AhR agonist, Laquinimod, present an elevation of the percentage of splenic CD4⁺ CD25⁺ Foxp3⁺ cells compared to vehicle treated animals^{194,196,286}.

On the other hand, it is known that AhR signaling triggered by physiological ligands is an important regulator of murine and human T_{regs} differentiation¹³⁷. Furthermore, Laquinimod treatment has been shown to be unable to alter T_{regs} frequencies in AhR KO mice compared to control littermates¹⁹⁴.

As a subpopulation of CD4⁺ T cells, T_{regs} were defined by the expression of the transcription factor FoxP3 and the surface marker CD25 as shown in figure 22. Flow cytometry analysis (described in section 2.4.8.2) showed that Laquinimod treatment increased the percentage of T_{regs} in EAE mice devoid of AhR in DC (p=0.0007), T_{regs} (p=0.0002) and CD4 T cells (p=0.03), corresponding to figure 22B, C and D, as well as in AhR^{fl/fl} control animals (figure 22A, p=0.005).

In contrast to an impaired suppression of Th17 cells in AhR^{DC} mice treated with Laquinimod, AhR competent DC, CD4⁺ T cells or FoxP3⁺ T cells were not required in Laquinimod treated mice to increase the percentage of T_{regs}.

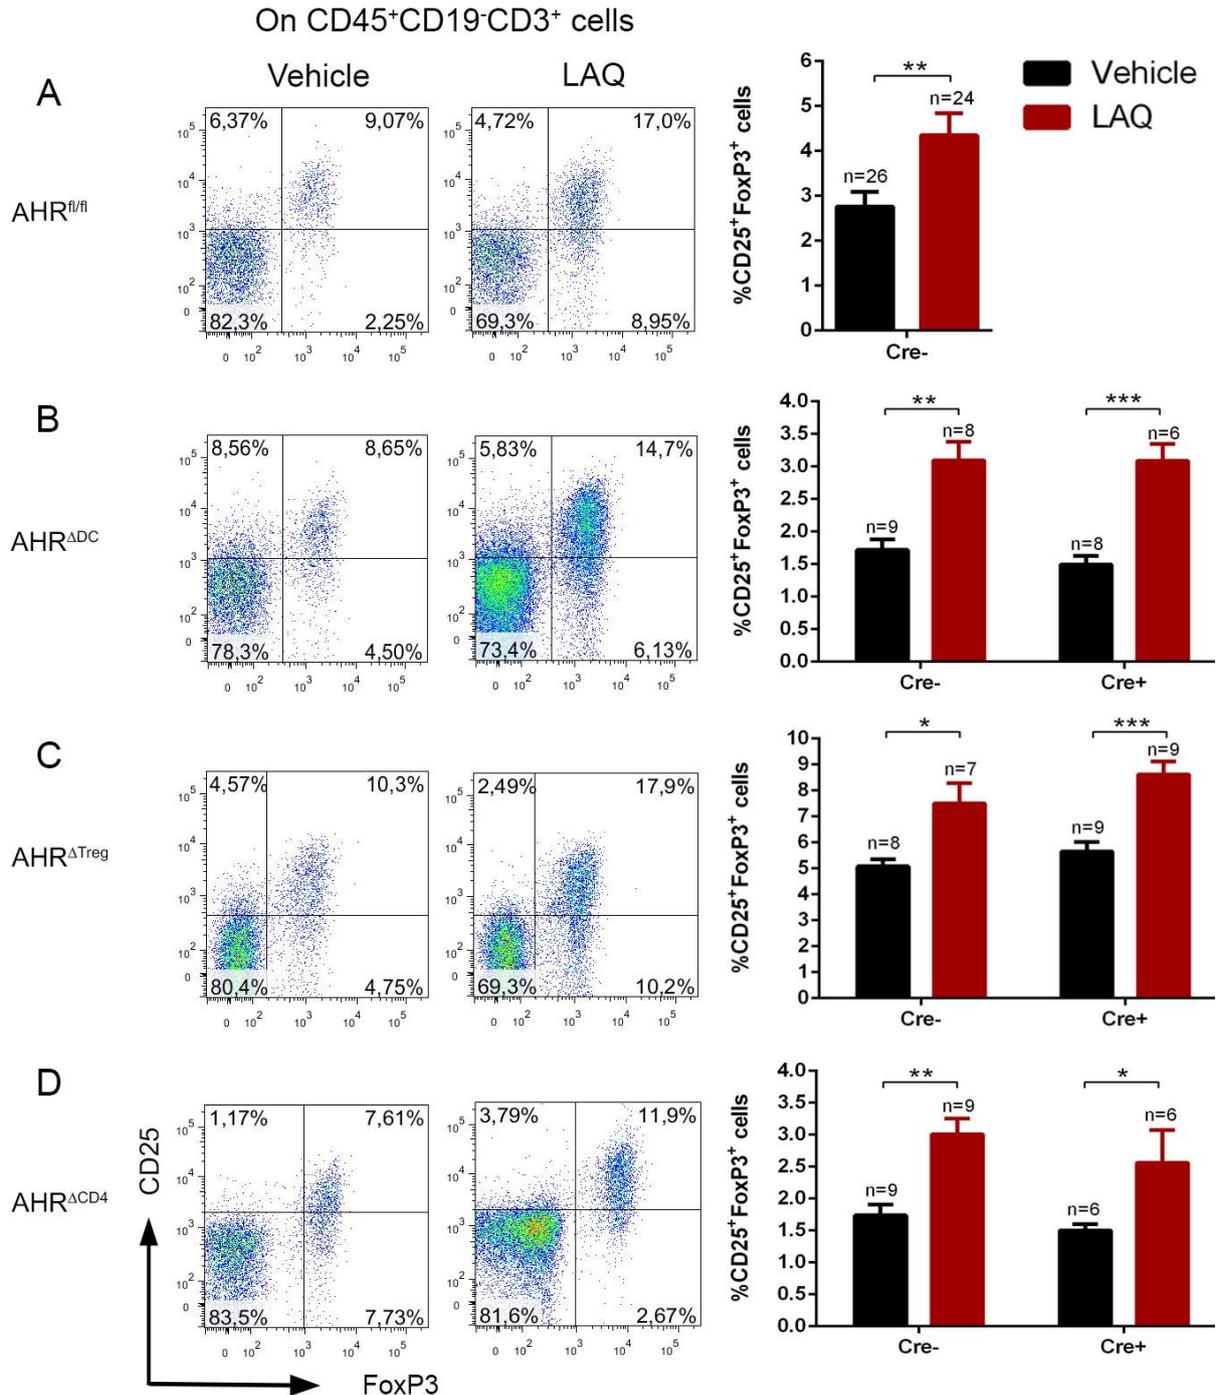

Figure 22. Laquinimod increases the percentage of CD25⁺FoxP3⁺ cells in *AhR^{ADC}*, *AhR^{ΔTreg}* and *AhR^{ΔCD4}* animals. Representative FACS dot plots showing the expression of CD25 and FoxP3 in T cells of (A) *AhR^{fl/fl}* control mice, (B) *AhR^{ADC}*, (C) *AhR^{ΔTreg}* and (D) *AhR^{ΔCD4}* animals treated with Laquinimod (25 mg/kg_{body weight}) or vehicle from the day of immunization to day 10 p.i. CD25⁺FoxP3⁺ cells were *ex vivo* analyzed by flow cytometry and presented as percentage from the total lymphocyte count (CD45⁺ cells), except for the cells obtained from *AhR^{ΔTreg}* mice (YFP labeled FoxP3⁺ cells), which are expressed as a percentage of the CD19⁻CD3⁺ cells. Data are shown as mean ± SEM and are pooled from three independent experiments. **p*<0.05, ***p*<0.01, ****p*<0.001, Mann-Whitney U-test.

3.3.7 NK cell activation by Laquinimod is independent of AhR expression on DC and CD4⁺ T cells

NK cells are effectors of the innate immune system that constantly monitor stressed, infected or abnormally proliferating cells. NK cells belong to the innate lymphoid cell (ILC) family²⁸⁷, which has been shown to require AhR signaling in many of its subsets to differentiate and survive²⁸⁸. It has been shown that AhR activation through tryptophan derived ligands potentiates NK cell activation leading to cytokine production, cytolytic and tumor control activity²⁸⁹.

The interplay between NK and DC potentially elicits cell activation and maturation of both cell types and impacts on CD4⁺ T cell responses²⁹⁰. Previous work from our group has shown that Laquinimod activates NK cells *in vivo* and *in vitro* and CD69 was among the NK cell markers upregulated by laquinimod treatment.

Ex vivo purified NK cells from Laquinimod treated mice killed B16F10 melanoma cells *in vitro* more efficiently than NK cells isolated from vehicle treated littermates. Furthermore, in a co-culture system with DC and MOG specific CD4⁺ T cells, NK cells from Laquinimod treated mice inhibited T cell proliferation better than NK cells from vehicle treated animals. This inhibition required cell to cell contact of NK cells with DC. Additionally, the depletion of NK cells impaired the efficacy of Laquinimod to suppress EAE [*in revision*].

In order to evaluate NK cell activation in response to Laquinimod administration and in the absence of AhR in different immune cell players relevant for its signaling, expression of the activation marker CD69 was measured by flow cytometry in splenic NK cells obtained from AhR^{ΔDC}, AhR^{ΔTreg}, and AhR^{ΔCD4} mice immunized with MOG₃₅₋₅₅.

Laquinimod treatment increased the early activation marker CD69 in NK cells obtained from AhR^{fl/fl} control mice (figure 23A, p=0.032) and all cell specific AhR KO mice, including AhR^{ΔDC} (p=0.029), AhR^{ΔTreg} (p=0.015) and AhR^{ΔCD4} mice (p=0.006) corresponding to figure 23B, C and D, as well as in their corresponding AhR competent controls (p=0.022, 0.0003, 0.022).

On CD45⁺CD19⁻CD3⁻NK1.1⁺ cells

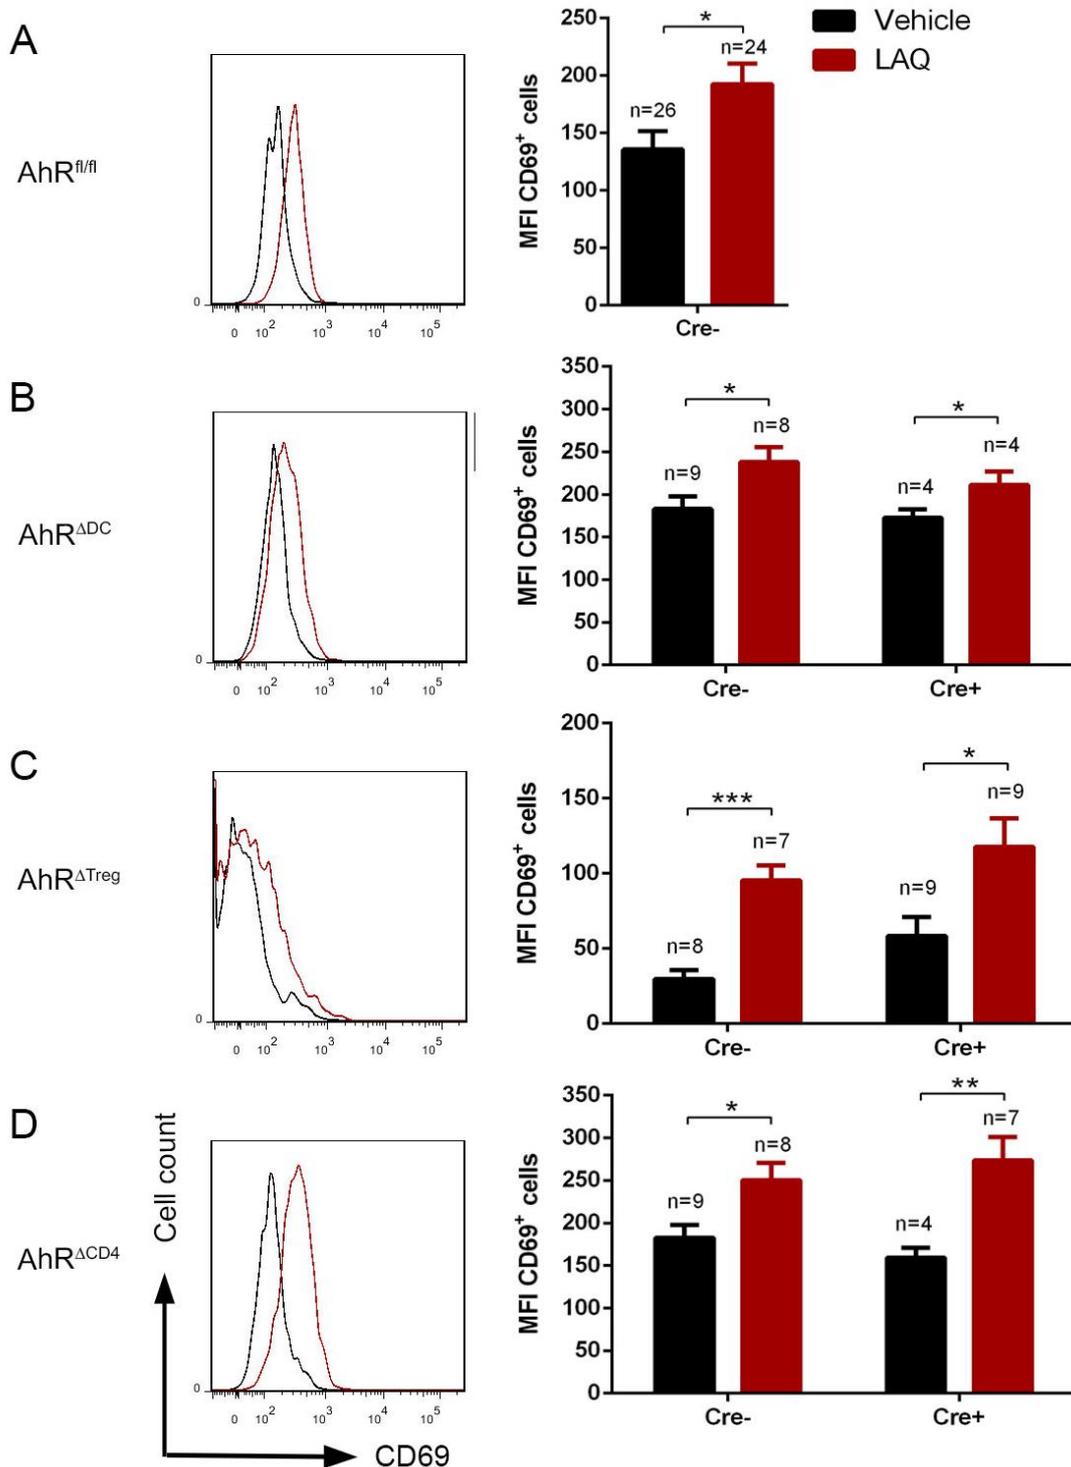

Figure 23. Laquinimod activates NK cells in the absence of AhR competent CD4⁺ T cells or DC. FACS histograms of CD69 expression on the surface of splenic NK cells obtained from (A) AhR^{fl/fl} control mice, (B) AhR^{ΔDC}, (C) AhR^{ΔTreg} and (D) AhR^{ΔCD4} animals treated with Laquinimod (25 mg/kg_{body weight}) or vehicle from the day of immunization to day 10 p.i. The CD69 MFI of the bar graphs is depicted as mean ± SEM pooled from 3 independent experiments. *p<0.05, **p<0.01, ***p<0.001, Mann-Whitney U-test.

3.3.8 Laquinimod reduces pulmonary B16F10 metastases

NK cells' antitumor functions have been extensively studied in different cancer models²⁹¹. They are usually more effective impairing the metastatic spread of malignant cells in the blood stream than reducing the size of established tumors. *In vivo* and *in vitro* approaches have previously shown that AhR activation enhances the anti-tumor properties and cytolytic activity of NK cells in the murine model^{289,292}.

Laquinimod mediated control of B16F10 melanoma metastases was evaluated *in vivo* using two experimental approaches. In a first model Laquinimod was preventively administrated to C57BL/6 and AhR KO mice before i.v. injection of B16F10 melanoma cells (figure 24A). In a second model the treatment of Laquinimod was initiated in C57BL/6 mice with established metastases 11 days after i.v. B16F10 melanoma cell injection (figure 24B).

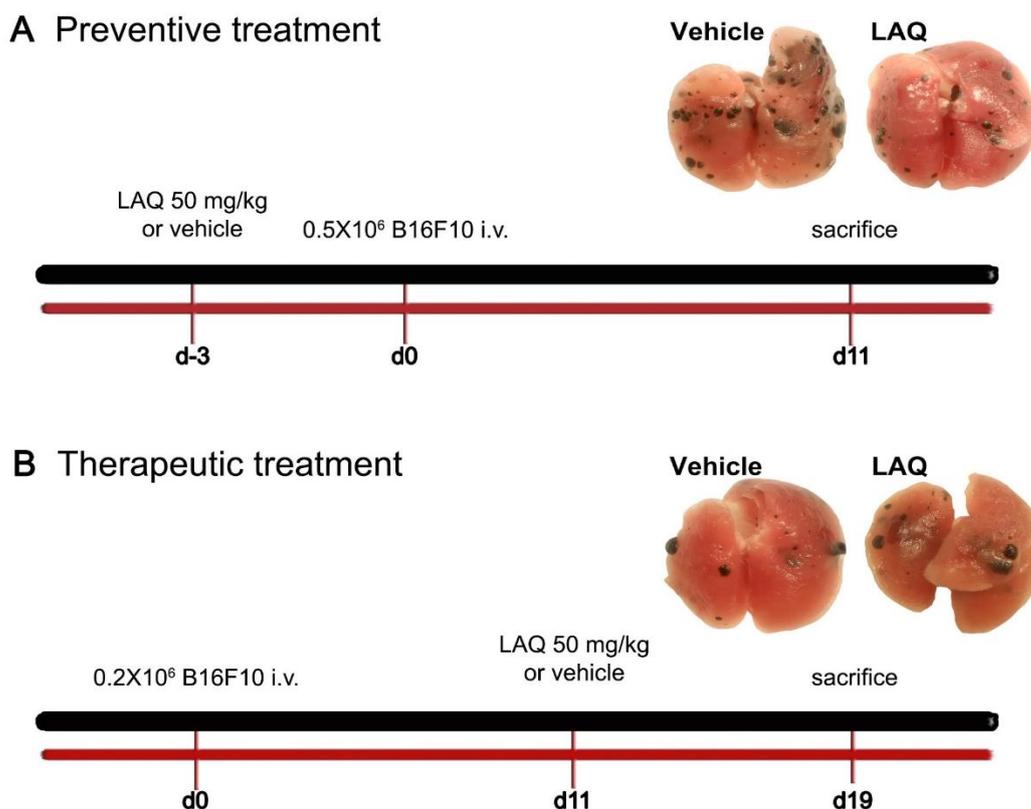

Figure 24. Preventive and therapeutic approaches used to study the efficacy of Laquinimod to suppress B16F10 melanoma metastases *in vivo*. Timelines corresponding to the (A) preventive and (B) therapeutic approaches. Animals submitted to the preventive treatment received daily Laquinimod administration starting three days before the i.v. transfer with 0.5×10^6 B16F10 melanoma cells and the lungs were isolated 10 days after inoculation. Mice under a therapeutic regimen were sacrificed 19 days after i.v. injection of 0.2×10^6 B16F10 melanoma cells and Laquinimod treatment was started 11 days after tumor inoculation.

Laquinimod was administrated in a dosis of 50 mg/kg_{body weight} and vehicle treated littermates were used as control. After preventive or therapeutic regimens the mice were sacrificed and the metastatic burden was quantified in the lungs as described in 2.4.12.3.

C57BL/6 animals preventively treated with Laquinimod showed a decrease in the number of metastatic colonies in the lungs (figure 25B) compared to vehicle treated mice ($p=0.04$). These results were confirmed by assessing the total lung weight, showing that the lungs obtained from mice receiving Laquinimod weighted significantly less ($p=0.001$) than those isolated from control animals (figure 25A).

When the same experiment was repeated with Laquinimod or vehicle treated AhR KO animals, the drug's protective effect was abolished. Vehicle treated AhR KO animals had less pulmonary metastases than vehicle treated C57BL/6 mice, which were not further reduced by laquinimod treatment. (figure 25D). In addition, Laquinimod was ineffective to reduce the number of already established pulmonary metastases (figure 25C).

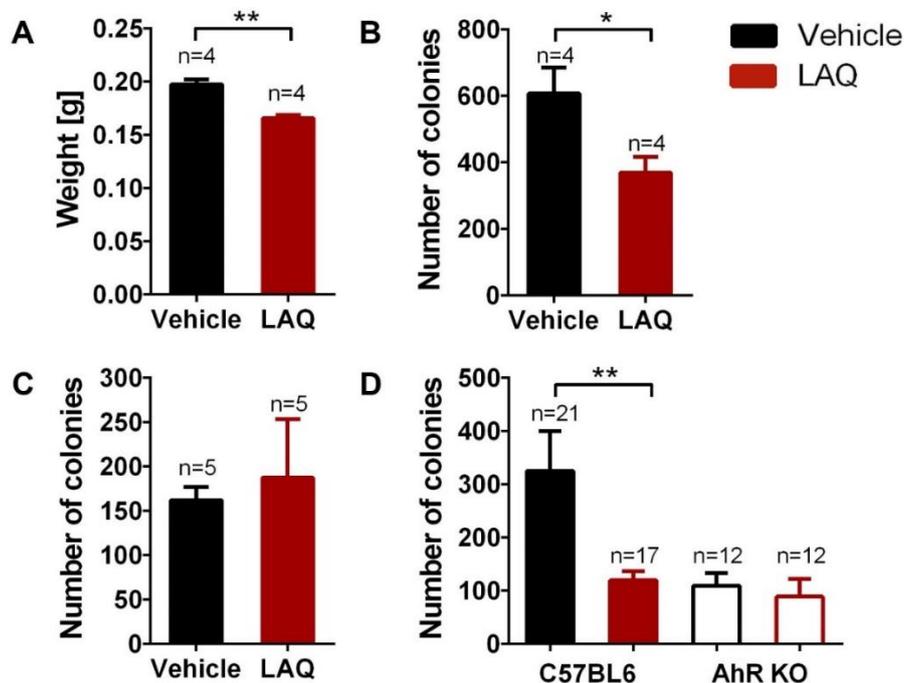

Figure 25. Laquinimod reduces the number of pulmonary B16F10 metastases if given preventively. (A) Pre-fixation total lung weight and (B) number of pulmonary metastatic colonies observed in WT mice receiving preventive daily oral gavage of Laquinimod 50mg/kg_{body} compared to water treated controls. (C) Number of pulmonary B16F10 metastases of mice submitted to the therapeutic regimen. (D) Number of pulmonary metastases in B16F10 melanoma cell-transferred C57BL/6J and AhR^{-/-} mice treated with Laquinimod or vehicle prior to the tumor cell challenge.

4. DISCUSSION

There is increasing evidence that the gut microbiome found in demyelinating CNS diseases such as MS and NMO might differ from the gut microbiome found in healthy controls^{293–296}. While the causality of these findings needs to be clarified in the light of potential confounders from comorbidity to concomitant medications, growing experimental evidence from a number of transgenic animal models shows that the germ status of the animal facility influences the incidence of spontaneous autoimmunity as in MBP TCR transgenic mice²⁹⁷. Dysbiosis of the gastrointestinal microflora promotes the differentiation of proinflammatory T cells and organ-specific autoimmunity^{118,121}. OSE mice raised in germ-free conditions are impervious to spontaneous EAE¹⁰³, suggesting that the intestinal microbiome contributes to the priming of pathogenic transgenic T cells.

The AhR is a ligand activated transcription factor that participates in broad molecular interactions, including the interplay of the immune system, diet and microbiome. The last two provide a wide range of AhR ligands leading to different effects on immune homeostasis such as control of T_{regs} and Th17 responses, dampen of DC maturation and regulation of gastrointestinal tolerance or inflammation mechanisms⁷⁴. The present study is mainly focused on the influence of AhR expression in CNS autoimmunity and its modulation by natural ligands that can be ingested through the diet.

In the first part, a dramatic decrease in the spontaneous EAE incidence was observed in the OSE mouse model after altering one AhR ligand in their diet. Next, the repercussions of the specific AhR deletion in astrocytes and immune cells, such as DC, CD4⁺ T cells and T_{regs}, were evaluated in the spontaneous EAE incidence, maximum disease scores and EAE severity of the OSE mice. Due to the effect of AhR deletion in DC, which significantly increased the disease incidence in this transgenic line, a closer look was taken into the APCs compartment and the CD4⁺ T cell proinflammatory cytokines production of the OSE mice.

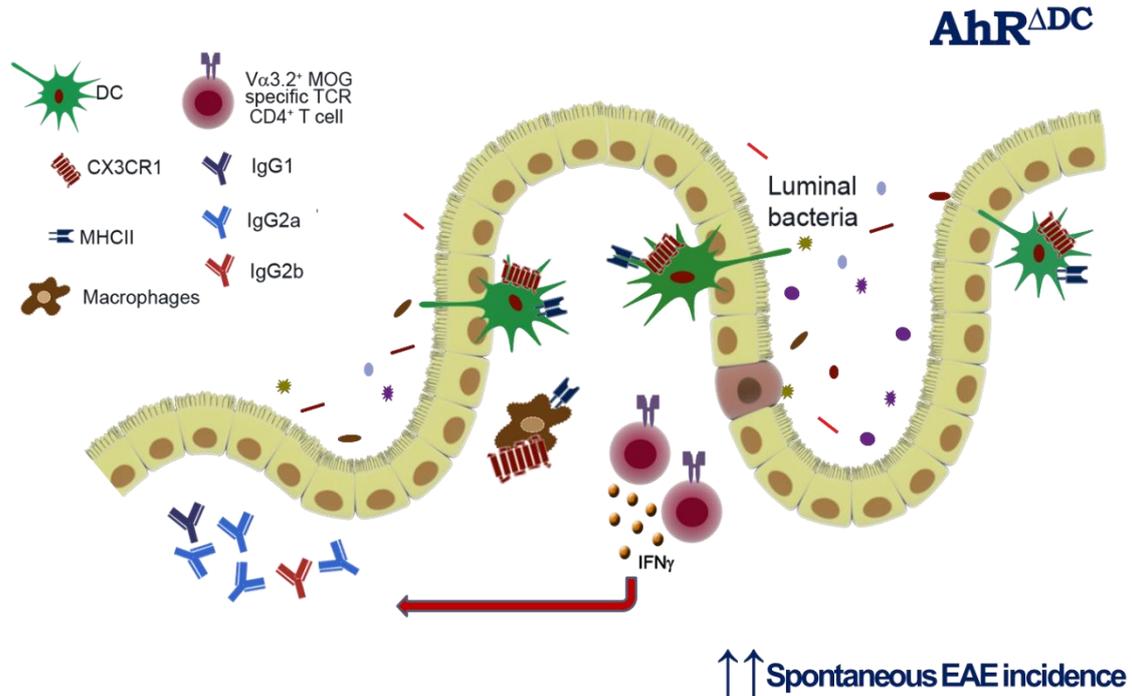

Figure 26. Graphical summary of the observed effects in the OSE mouse model harboring an AhR deletion in DC. Schematic representation of the small intestines of OSE $AhR^{fl/fl} CX3CR1^{EGFP/+}$. OSE mice lacking AhR in DC showed higher frequencies of LP $CX3CR1^{int}$ DC (depicted in green) and IFN γ producing $V\alpha 3.2^+$ MOG specific TCR $CD4^+$ T cells (depicted in red-brown). Isotype switching towards IgG2a secretion was enhanced and the spontaneous EAE incidence in OSE $AhR^{\Delta DC} CX3CR1^{EGFP/+}$ mice doubled in comparison to their OSE AhR competent littermates. DC might capture luminal antigens by extending transepithelial dendrites.

As shown in the graphical summary (figure 26), the specific AhR deletion in $CD11c^+$ cells led to an increase in the frequencies of $CX3CR1^{int}$ DC compared to $CX3CR1^-$ DC measured in the LP of the OSE $AhR^{\Delta DC} CX3CR1^{EGFP/+}$ reporter mice. Besides, higher expression of MHCII was quantified in $CX3CR1^{int}$ DC, suggesting that OSE $AhR^{\Delta DC} CX3CR1^{EGFP/+}$ might exhibit DC that are better prepared for antigen presentation. In addition, a discrete increase of the IFN γ producing $V\alpha 3.2^+$ MOG specific TCR $CD4^+$ T cells was shown in the LP of these transgenic animals, which supports the increase of IgG2a secretion measured in the OSE mice sera.

In the last part, Laquinimod, a presumed AhR ligand known by its immunomodulatory effects in DC and $CD4^+$ T cells, was tested in AhR specific KO animals. Laquinimod's therapeutic effect seemed to be attenuated by AhR expression in DC. On the one hand, all transgenic mice with AhR deletion in DC, $CD4^+$ T cells, T_{regs} or astrocytes, were protected from

EAE by the drug, even though in a less sustained way in AhR^{ΔDC} mice. On the other hand, the frequencies of IL17 producing CD4⁺ T cells were reduced in mice lacking AhR in CD4⁺ T cells but not in animals devoid of AhR in DC.

4.1 AhR deletion in DC doubles disease incidence in the OSE mouse model

Research conducted in AhR KO mice has shown important implications on Th17 and T_{regs} responding to AhR signals. Yet there was no previous evidence on a spontaneous EAE model reporting the particular repercussions of AhR specific deletion in DC, astrocytes and CD4⁺ cells.

The data presented in figure 7A showed that the lack of AhR in DC doubles the occurrence of spontaneous CNS autoimmunity in the OSE mice. This results support that physiological AhR ligands in the regular animal diet influence the development of spontaneous CNS autoimmunity via AhR competent DC²⁸⁸.

AhR ablation in CD11c⁺ (figure 7A) cells but not in GFAP⁺ and CD4⁺ (figure 6A and D) led to a significant increase in the spontaneous EAE incidence suggesting important regulatory functions of AhR signaling in DC and certain macrophages subsets.

DC are the most potent APCs modulating immune responses and they express high AhR protein levels¹³¹. Intestinal DC have important functions maintaining the integrity of the epithelial barrier by continuously sensing gut lumen antigens. Due to their close proximity to commensal bacteria, the activation status of intestinal DC and APCs has to be tightly regulated. Imbalanced APCs might contribute to the development of gut specific autoimmunity^{298,299}.

AhR in DC has been demonstrated to act through the Wnt signaling regulating mucosal immunity and development. For example, AhR deficient DC have a direct effect in the intestine morphogenesis affecting the differentiation of secretory epithelial cells, such as goblet and Paneth cells¹⁷³. Impairment of AhR in DC is enough to elicit gut epithelium dysfunction and to increase the propensity to bowel inflammation. The disruption of the intestinal epithelium's

integrity is considered an early EAE event, which may support disease progression and worsening³⁰⁰.

AhR^{fl/+} CD11c^{Cre+} R26R^{eYFP} and AhR^{fl/-} CD11c^{Cre+} R26R^{eYFP} mice were generated in order to sort out AhR competent and AhR deficient DC *ex vivo*. More than 90% of the MACS purified DC were YFP labeled. Besides, CYP1A1, a prototypic AhR regulated gene, is readily induced by FICZ in sorted YFP⁺ DC of AhR^{fl/+} CD11c^{Cre+} R26R^{eYFP} mice (AhR competent), but not in YFP⁺ DC purified from AhR^{fl/-} CD11c^{Cre+} R26R^{eYFP} mice (AhR deficient). Thus, this model might be valuable to further dissect the DC phenotype and to generate functional data with AhR competent or deficient DC.

4.2 Evaluation of intestinal APCs in the OSE AHR^{ADC} mice

Taking a closer look into the intestinal APCs compartment, AhR deficient and AhR competent DC were characterized in OSE AHR^{ADC} and OSE AHR^{fl/fl} mice, respectively. Since the LP is the mucosal effector site where most of the APCs reside and contribute to the gastrointestinal immune system, DC were obtained and characterize from this compartment.

DC have a unique feature that allows them to migrate from the intestine to the mesenteric lymph nodes in the vicinity starting adaptive immune responses by priming naive T cells. Macrophages are LP residents and thus, unlikely to play a major role in the priming of naive cells. As innate effector cells, macrophages engulf and clear bacteria, secrete cytokines, and maintain intestinal homeostasis They are also very abundant and express CD11c⁺ in some subsets, which is considered a prototypical DC marker^{301–304}.

Besides the ability to migrate, the intestinal APCs can be differentiated by the expression of cell surface markers. The chemokine receptor CX3CR1 (fractalkine receptor) and the high affinity IgG receptor FcγR CD64 were used to evaluate the different APCs population through a consistent gating approach. The fractalkine receptor (CX3CR1) is often used to characterize functionally and phenotypically different subsets of the intestinal immune cells, being present in the LP DC (CX3CR1^{int}) and macrophages (CX3CR1^{high})^{301,302,305,306}.

The lack of AhR in DC affected the composition of the APCs compartment in the lamina propria of the OSE AhR^{ΔDC} CX3CR1^{EGFP/+} reporter mice by increasing the percentage of CX3CR1^{int} DC while decreasing the percentage of CX3CR1⁻ DC.

Initial studies using CX3CR1^{EGFP/+} reporter mice suggested that DC could extend transepithelial dendrites (TED) through tight junctions in the epithelium to capture luminal bacteria³⁰⁷. Further studies proposed that TED formation was CX3CR1 dependent³⁰⁸

In addition, CD64 expression was used to distinguish DC from macrophages within the lymphocytes isolated from the gut (figure 8). Until now, CD64 seems to be the most reliable intestinal macrophage marker in the small and large bowel of humans and mice, under inflammation or steady state^{306,309} to unambiguously discriminate CX3CR1^{int} (CD64⁻) DC from CD11c⁺ (CD64⁺) macrophages.

Furthermore, the murine receptor F4/80 expressed in most tissue resident macrophages³¹⁰ was used to further characterize intestinal APCs, even though it is present in some DC subtypes, such as CD103⁻ CD11b⁺ DC³¹¹.

Of note, CX3CR1^{int} DC showed higher expression of MHCII by flow cytometry than CX3CR1⁻ DC. Also the CD64⁺ F4/80⁺ CX₃CR1^{high} macrophage population in the OSE AhR^{ΔDC} CX3CR1^{EGFP/+} mice expressed higher levels of MHCII and lower levels of F4/80 compared to the CD64⁺ F4/80⁺ CX₃CR1^{high} macrophages of OSE AhR^{fl/fl} CX₃CR1^{EGFP/+} mice, suggesting that macrophages are more activated in the OSE AhR^{ΔDC} CX3CR1^{EGFP/+} mice than in control animals.

During this project CD11c^{tdTomato} CX3CR1^{EGFP} reporter mice were generated in order to visualize the APC populations *in situ*, which were described by flow cytometry after tissue digestion. CD11c^{tdTomato} single and CD11c^{tdTomato} CX3CR1^{EGFP} double positive cells were mainly found in the LP of the small intestines while EGFP single positive cells were sparse (figure 10). Single TED were visualized using the same mice (figure 11).

4.3 OSE AHR^{ΔDC} mice produce higher amounts of IgG2a MOG antibody titers and IFN γ

The protective effect of ITE in EAE was attributed to the generation of tolerogenic DC, which secreted less proinflammatory cytokines but expressed similar MHC I, MHC II, CD40 or CD80 levels compared to DC obtained from vehicle treated controls.

It was tempting to speculate that the lack of AhR in DC might increase CX3CR1^{int} DC populations, which might be better equipped for luminal bacterial sampling. Thereby, the microbiological cues in the LP could increase and MOG specific CD4⁺ T cells could be better activated.

Therefore, it was next assessed if the frequency of MOG specific CD4⁺ T cells that produce proinflammatory cytokines is higher in the lamina propria of OSE AhR^{ΔDC} mice compared to OSE AhR^{fl/fl} control littermates.

Ex vivo analysis of CD4⁺ T cells isolated from that OSE AHR^{ΔDC} mice showed a moderate increase of IFN γ but not IL17 producing MOG specific T cells (figure 14D and F). Additionally, higher MOG specific IgG2a antibody titers were found in the serum of OSE AHR^{ΔDC} mice compared to control animals. These results correlate well with the higher production of IFN γ , known to influence immunoglobulin isotypes. Previous studies have shown that IFN γ inhibits IgG3, IgG2b, IgG1 and IgE secretion, whereas IgG2a production is enhanced^{279,312}.

IFN γ producing T cells seem to be particularly relevant for the OSE mouse model, since the IFN γ , but not the IL17 transcripts were increased in CNS lesions of these animals. Furthermore, *in vitro* stimulation of OSE splenocytes with MOG led to the secretion of IFN γ and IL17 to a lesser extent¹⁰¹.

Interestingly, studies using AhR KO mice showed an increase of IFN γ production compared to AhR competent animals. Similar results were found at mRNA level, when AhR

KO lymphocytes were analyzed and presented higher IFN γ levels than the WT ones, suggesting an AhR mediated downregulation of IFN γ ³¹³.

4.4 AhR effect on T cell differentiation

The lack of AhR in CD4⁺ T cells in the OSE mice did not change spontaneous EAE development and severity, suggesting that physiological amounts of AhR ligands do not modulate MOG specific CD4⁺ T cells directly or effectively enough to change spontaneous EAE. However, different publications have suggested a direct effect of the AhR on T cell differentiation.

It has been shown that AhR activation modulates *in vitro* Th17 differentiation and thus, IL17 and IL22 secretion, in splenic CD4⁺ T cells²⁸³ and intestinal $\gamma\delta$ T cells¹³³. The first publication showed that T cells express the AhR under Th17 polarizing conditions, whereas AhR deficiency reduces IL17 production of splenic naïve CD4⁺ T cells *in vitro*. In the second paper, it was shown a higher production of IL17 in AhR deficient $\gamma\delta$ T cells. Moreover, results obtained in a model of skin inflammation support these findings showing increased IL17 levels in the skin of AhR KO mice³¹⁴.

The AhR has been shown to play complex roles in the differentiation of T_{regs}¹⁴² and Th17 by modulating the activation of Stat1²⁸³ and through the generation of kynurenines by IDO in DC scattered within the gut microenvironment¹³⁵. Possibly, due to the strong implications of AhR signaling in IL17 producing T cells, it was unlikely that Th17 were increased in mice lacking AhR in DC.

4.5 AhR repercussions on astrocytes

Similarly, OSE mice which lacked AhR in astrocytes did not show any differences in the incidence of spontaneous EAE. Thus, the results presented in 3.1.2 disagree with Rothhammer and colleagues¹²⁶, who report that astrocytes can be exploited to suppress EAE if activated by AhR ligands.

As shown in figure 18b, an increased EAE susceptibility of vehicle treated AhR^{ΔAstro} mice was observed compared to vehicle treated AhR^{fl/fl} mice in our Laquinimod experiments performed with MOG₃₅₋₅₅ immunized animals, suggesting that the relevance of the astrocytic AhR in EAE might be model dependent.

4.6 EAE incidence can be altered by modifying AhR ligands in the diet

Although the AhR was exhaustively studied for its actions mediating the toxicity of certain xenobiotics, different physiological functions have been slowly unraveled in response to endogenous AhR ligands obtained from commensal bacteria and the diet.

Altering the composition of one natural AhR ligand, indol-3-carbinol (I3C), the disease incidence significantly dropped in a spontaneous EAE model. It was also shown that the OSE animals submitted to the I3C enriched diet possess the necessary immune elements to start an immune response and are fully susceptible to develop EAE if immunized (figure 5A and B).

Previous reports treating EAE immunized mice with potent AhR agonists obtained conflicting results with different outcomes depending on the mode of ligand application. For example, systemic administration of the high affinity AhR agonist FICZ (6-formylindolo[3,2-b]carbazole) by i.p. injection suppressed EAE¹⁴², whereas FICZ injection (incorporated to the antigen and CFA emulsion) exacerbated EAE pathology and promoted a Th17 response¹⁵⁹.

In contrast, the i.p. injection of the endogenous AhR ligand 2-(1'H-indole-3'carbonyl)-thiazole-4-carboxylic acid methyl ester (ITE) suppressed EAE¹⁷⁴ and the addition of tryptophan to the diet, which is metabolized to a number of AhR ligands by gut microbiota, ameliorates actively induced EAE as well¹²⁶. Ingestion of indole metabolites, phytochemicals and tryptophan seemed to unequivocally help to homeostasis maintenance at epithelial barriers by producing a vast variety of AhR ligands^{125,275}.

4.7 AhR mediated effect of Laquinimod on EAE

Laquinimod, a quinoline-3-carboxamide with immunomodulatory properties³¹⁵, has been presumed an AhR agonist based on the induction of CYP1A1 and AhRR (AhR repressor), two prototypical AhR regulated genes, in a number of tissues including the CNS¹⁹⁴.

Daily oral treatment with Laquinimod completely abolishes the development of murine EAE in an AhR dependent manner, as shown by Kaye and collaborators using AhR KO and bone marrow chimeras¹⁹⁴. It was previously demonstrated that the presence of AhR in the immune system is sufficient and necessary for Laquinimod's actions^{193,194}. However, the exact immune population that mediates Laquinimod's therapeutic effect remains to be demonstrated. Furthermore, there is no evidence that AhR expression is directly required one single cell type.

Cell specific AhR knockout mice were used in order to define which cellular players are relevant mediators of the therapeutic efficacy of Laquinimod, including mice devoid of AhR in DC, CD4⁺ T cells, T_{regs} and astrocytes (AhR^{ΔDC}, AhR^{ΔCD4}, AhR^{ΔTreg}, and AhR^{ΔAstro}).

All cell specific AhR KO mice were significantly protected by the drug as evidenced by a lack or delay of EAE symptoms in treated animals. In particular, Laquinimod treated AhR^{ΔCD4}, AhR^{ΔTreg}, and AhR^{ΔAstro} mice were protected against EAE similarly to Laquinimod treated AhR^{fl/fl} controls. The initial protection of AhR^{ΔDC} mice against EAE was less sustained over time and 2/3 of the animals developed EAE symptoms compared to 7% of the AhR^{fl/fl} mice.

If animals treated with Laquinimod developed clinical EAE at later time points, the mean maximum disease scores were not significantly different from water treated controls. This suggests that Laquinimod works better in the priming than the effector phase of EAE.

Previous experiments using C57BL/6 mice indicate that Laquinimod directly or indirectly regulates T cells through its influence on APCs^{179,181–183}. Thus, DC and T cells were the first compartments to be evaluated in all cell specific AhR KO mice treated with Laquinimod from the day of immunization.

Splenic T_{regs} were comparably induced in AhR^{ΔTreg}, AhR^{ΔCD4} and AhR^{fl/fl} mice by Laquinimod treatment. Decreased percentages of CD4⁺ T cells producing proinflammatory cytokines could be demonstrated equally well in Laquinimod treated AhR^{ΔCD4} and AhR^{fl/fl} mice. Nevertheless, their reduction was less impressive in AhR^{ΔDC} mice, suggesting that AhR competent DC might be required for Laquinimod to lower the percentage of CD4⁺ T cells producing proinflammatory cytokines, such as IL17. This indirect effect was astonishing given that Laquinimod reduced the percentage of CD11c⁺ MHCII^{high} DC in all Cre lines including treated AhR^{ΔDC} mice.

AhR activation in DC has been shown to promote a tolerogenic phenotype and the TCCD mediated activation of the AhR induced the expression of the potent immunosuppressive enzyme IDO in DC³¹⁶. Laquinimod therapy completely abolished EAE development in IDO deficient mice, demonstrating that a functional IDO1-AhR axis was not required.

The absence of AhR in astrocytes did not significantly impair the efficacy of the drug suppressing EAE. As mentioned in the previous section, AhR^{ΔAstro} mice that were MOG immunized and vehicle treated developed more severe EAE compared to vehicle treated AhR^{fl/fl} mice, arguing for a higher susceptibility to develop EAE.

Supporting these data (table 22 and figure 18B), Rothhammer et al¹²⁶ has previously shown that AhR^{ΔAstro} mice experience worsening of the EAE scores compared to control animals. Additionally, they used a lentivirus construct with an AhR targeting shRNA expressed under the control of the GFAP promoter to prove that the increase of the disease severity was due to lack of the expression of AhR in astrocytes and not in GFAP⁺ cells outside the CNS.

4.7.1 Laquinimod effect on NK cell cytotoxicity

Previous results of our group demonstrated that Laquinimod effectively activates NK cells *in vivo* and *in vitro*. NK cells contribution to Laquinimod's therapeutic efficacy has been observed *in vivo* by a marked reduction of the drug's protective effect in EAE after NK cell depletion. Additionally, Laquinimod improved NK cell mediated killing of B16F10 melanoma cells *in vitro*.

Figure 20 shows a consistent elevation of the activation marker CD69 in NK1.1⁺ cells obtained from Laquinimod treated mice from the day of immunization. However, AhR competent DC and CD4⁺ T cells were not required for NK cell activation after Laquinimod treatment.

Next, the ability of Laquinimod to suppress B16F10 melanoma cell metastases was evaluated *in vivo* using preventive and therapeutic approaches. Daily oral Laquinimod treatment significantly decreased lung metastasis if given before B16F10 melanoma cells were i.v. transferred.

Even though AhR KO mice developed less metastases than C57BL/6 controls, Laquinimod failed to reduce the number of B16F10 metastases further, suggesting the AhR mediated activation of NK cells might contribute to B16F10 metastasis control.

It has been shown that AhR modulates the differentiation and activation of murine²⁸⁹ and human³¹⁷ NK cells. In humans, CD56^{bright} NK cells were shown as highly sensitive to AhR ligands, which modulate their activation, receptor expression, cytokine production and antitumor capacity³¹⁷. Besides, the expression of AhR in NK cell developmental intermediates regulates their interaction with conventional DC within secondary lymphoid tissue modulating mucosal immunity during infection²⁹²

In mice, NK cell tumor control is significantly enhanced *in vivo* by administering endogenous AhR ligands in WT mice inoculated with murine lymphoma RMA-S cells. Such inhibition of tumor growth is AhR dependent because its protection is completely abolished in AhR KO mice. Besides, AhR deficient NK cells have reduced cytolytic activity and antitumor

effector functions²⁸⁹ and liver resident NK cells lacking AhR have an impairment of their maintenance and memory³¹⁸.

4.7.2 Final remarks on AhR mediated Laquinimod's effect

Taking all these data together leads to different possible hypotheses. For instance, Laquinimod's protection could require downstream targets of AhR signaling. Due to its promiscuity, the AhR signaling network is involved in different cellular processes and it is able to activate different pathways depending on the agonist that triggered the cascade³¹⁹ For example, Laquinimod induction of T_{regs} responses is probably occurring through different mechanisms to the AhR signaling activated by tryptophan metabolites (which induce IDO expression in DC and lead as well to T_{regs} responses)^{131,285,298,320}.

An alternative hypothesis would consider that Laquinimod's protection is not limited by one single cell player expressing AhR but rather regulated by the interplay of different AhR competent cells. It is also possible that Laquinimod's therapeutic efficacy might require AhR competent macrophages or B cells, which were not approached in the present thesis.

In summary, the most likely scenario is that additional cell types are involved in mediating the protective efficacy of Laquinimod and that the AhR is not the only receptor mediating the protective effect of the drug.

5. OUTLOOK

The present thesis showed that AhR deletion in DC augments spontaneous CNS autoimmunity, elevates the percentage of LP CX3CR1^{int} DC and induces a moderate increase of IFN γ producing MOG specific CD4⁺ T cells. It was also shown that dietary supplementation with I3C, an AhR ligand present in cruciferous vegetables, effectively suppresses spontaneous CNS autoimmunity of AhR competent OSE mice. In further experiments newly developed tools will allow us to understand the aforementioned observations better:

In order to clarify if the AhR deficiency in DC leads to local or more disseminated changes in the APCs compartment, their analysis in the OSE AhR Δ DC CX3CR1^{EGFP/+} and OSE AhR^{fl/fl} CX3CR1^{EGFP/+} reporter mice will be extended to the Peyer's patches, mesenteric lymph nodes and spleen.

Subsequently, it would be interesting to characterize in more detail the AhR^{fl/+} CD11c^{Cre+} R26R^{eYFP} and AhR^{fl/-} CD11c^{Cre+} R26R^{eYFP} mice and to further confirm the AhR deficiency in YFP⁺ DC in the latter. AhR competent or AhR deficient YFP⁺ DC could be sorted and used for RNA sequencing analyses or functional *ex vivo* studies with naïve MOG specific T cells as responders.

Due to the changes observed in the APCs compartment of the OSE AhR Δ DC CX3CR1^{EGFP/+} reporter mice, *in vitro* and *in vivo* functional studies would be desirable to test the APCs immunogenic capacity to prime T cells. *In vivo*, adoptive transfer of MOG specific RFP labeled V α 3.2⁺ CD4⁺ T cells into AhR^{fl/-} CD11c^{Cre+} R26R^{eYFP} mice or OSE AhR Δ DC CX3CR1^{EGFP/+} animals to analyze if MOG specific T cells colocalize with LP DC and differentiate into better cytokine producers in mice expressing AhR deficient DC. *In vitro*, co-cultures of MOG specific RFP labeled V α 3.2⁺ CD4⁺ T cells and intestinal DC sorted from AhR^{fl/-} CD11c^{Cre+} R26R^{eYFP} mice would allow to measure T cell activation and proliferation.

This work provided compelling evidence of the regulatory role of the AhR in spontaneous CNS autoimmunity. It was shown that the increase of one single AhR ligand (I3C)

dramatically diminished disease incidence in a model of spontaneous EAE. Having available the molecular tools, it would be interesting to evaluate which are the most relevant cells mediating AhR's actions through the diet. Therefore, following experiments aim to study the effect of the chemically defined diet (E1500) supplemented with I3C^{2mg/kg} in the cell specific AhR KO mice (OSE AhR^{ΔDC}, OSE AhR^{ΔCD4} and OSE AhR^{ΔAstro} transgenic lines). Furthermore, it will be investigated if the I3C supplied in the chow decreases the percentage of LP CX3CR1^{int} DC obtained from the small intestines.

Furthermore, spontaneous stool samples and the contents of the small intestines of OSE mice (kept under a regular, chemically defined or I3C^{2mg/kg} enriched chemically defined diet) have been snap frozen during this project. The next step will be to use the samples to characterize the composition and differences between the gut microbiomes.

The results obtained in this thesis indicated that Laquinimod's protection is either supported by additional cell types apart from the ones studied or is conferred by an effect on multiple cell types simultaneously. That is why it would be necessary to test mice with AhR deleted in further cell types, such as B cells, macrophages and NK cells (AhR^{ΔMac}, AhR^{ΔBcell} and AhR^{ΔNKcell}) using the corresponding Cre lines (LysM^{Cre}, NKp46^{Cre} and mb1^{Cre} mice). Furthermore, it is likely that AhR independent effects contribute to Laquinimod's protection from autoimmunity.

6. CONCLUSIONS

CNS autoimmune diseases are likely caused by a complex interplay of genetic and environmental factors. One of the well-established environmental sensors is the aryl hydrocarbon receptor (AhR), which is widely expressed in the immune and central nervous system (CNS). The AhR is not only activated by pollutants such as TCDD but also by a number of physiological ligands of the diet, the commensal flora and diverse metabolites produced by the host.

This study assessed if the incidence and severity of spontaneous EAE in OSE mice are modified by the selective deletion of AhR in immune cells (including DC, CD4⁺ T cells and T_{regs}) or in CNS resident cells, such as astrocytes. AhR deletion in CD11c⁺ cells significantly increased spontaneous EAE incidence in the OSE mice. In contrast, OSE animals lacking AhR competent CD4⁺ T cells, T_{regs} or astrocytes did not differ to OSE AhR^{fl/fl} control littermates in their ability to mount a CNS autoimmune response.

Using OSE AhR^{ΔDC} CX3CR1^{EGFP/+} reporter mice, it was demonstrated that AhR deficiency led to changes in the intestinal APCs by upregulating the percentage of DC intermediately expressing CX3CR1 (CX3CR1^{int} DC) in the lamina propria (LP) of OSE mice. CX3CR1⁺ DC expressed higher levels of MHCII compared to CX3CR1⁻ DC. Therefore, they might be better equipped to mount a CD4⁺ T cell response.

Generating CD11c^{tdTomato} CX3CR1^{EGFP} transgenic mice, the presence of CD11c⁺ and CD11c⁺ CX3CR1⁺ double positive DC was confirmed in histological sections of the intestinal LP. Interestingly, a number of previous studies emphasized the unique ability of CX3CR1⁺ DC in the LP to sample gut bacteria.

The ablation of AhR competent DC in OSE mice increased the frequency of IFN γ producing MOG specific CD4⁺ T cells in the LP and led to higher titers of MOG specific IgG2a antibodies in the sera of the mice.

Demonstrating the therapeutic potential of AhR targeted medications, the spontaneous EAE was almost completely abolished in OSE mice by increasing the dietary intake of one single AhR ligand present in cruciferous vegetables, the indol-3-carbinol (I3C).

While AhR deletion in astrocytes did not influence spontaneous autoimmunity in the OSE mouse model, it worsened EAE in MOG₃₅₋₅₅ immunized AhR^{ΔAstro} mice suggesting that the relevance of astrocytic AhR might be model dependent.

Laquinimod is a presumed AhR agonist, which was moderately effective in reducing relapse rates in clinical trials with RRMS patients. Cell specific AhR knock out mice were generated in order to analyze which cell type is relevant for the therapeutic efficacy of Laquinimod to suppress EAE. Laquinimod treatment protected all cell specific AhR deficient mice against EAE. However, its protective effect was less sustained in AhR^{ΔDC} mice. Moreover, Laquinimod reduced the percentage of IL17 producing CD4⁺ T cells in AhR^{ΔCD4} mice but not in AhR^{ΔDC} animals, arguing for a rather indirect effect of the drug on T cells.

In summary, it was demonstrated that physiological concentrations of AhR ligands modulate spontaneous autoimmunity via AhR competent DC. Additionally, MS patients might benefit from increasing their dietary uptake of AhR ligands

8. CURRICULUM VITAE

Erika Avendaño Guzmán

e.avendanoguzman@gmail.com

| | |
|-----------------------|-----------------------------|
| Nationality | Mexican |
| Date of birth | May 6th, 1988 |
| Place of birth | Tlalnepantla de Baz, México |

▪ EDUCATION:

- 2014 - 2018 **PhD student** Institute for Neuropathology, University of Göttingen, IMPRS (member of the International Max Planck Research School). Neuroscience graduate program, Göttingen, Germany.
- 2012 - 2014 **M.Sc. student** University of Göttingen, IMPRS Neuroscience graduate program, Göttingen, Germany.
- 2007 - 2011 **B.Sc. (Biology) Honorific Mention.** (Class rank: 2 of 1,756) Universidad Nacional Autónoma de México, Mexico City, Mexico.
- 2004 - 2007 **High school Honorific Mention.** (Class rank: 3 of ~1000) Instituto Tecnológico de Monterrey, Mexico City, Mexico.
- 2000 - 2004 **Secondary school. Honorific Mention.** (Class rank: 1 of 52) Liceo Ibérico Americano, Mexico City, Mexico.

▪ PROJECTS / RESEARCH:

- 09/2014 - 10/2018 **Evaluating the function of the Aryl Hydrocarbon Receptor in CNS autoimmunity.** PhD project at the Neuropathology department (Prof. Wolfgang Brück) of the University Medical Center Göttingen (UMG), Göttingen, Germany.
- 10/2013 - 07/2014 **Role of N-truncated A β 4-x and A β 5-x in Alzheimer's disease.** Master's project at the division of Molecular Psychiatry (Prof. Thomas Bayer) of the UMG, Göttingen, Germany.
- 05/2013 - 06/2013 **Activity dependent expression of TRPV1 in hippocampal neurons.** Lab rotation at the Trans-synaptic signaling department (Camin Dean, PhD) of the European Neuroscience Institute, Göttingen, Germany.
- 03/2013 - 05/2013 **Evaluation of antibody signal intensity and specificity in colorimetric and fluorescent protein microarray applications.** Lab rotation at the R&D Diagnostic Membranes department (Dr. Denise van Rossum) of Sartorius Stedim Biotech GmbH, Göttingen, Germany.
- 01/2013 - 03/2013 **Involvement of synaptic molecules in synapse formation and maturation.** Lab rotation at the Anatomy and Embryology department (Prof. Thomas Dresbach) of the Center for Anatomy, UMG, Göttingen, Germany.
- 08/2010 - 02/2012 **Role of reactive oxygen species in BDNF and NMDA trophic actions using cerebellar granule cells.** Bachelor's thesis project at the Neurodevelopment and Physiology department (Prof. Julio Morán Andrade) of the Universidad Nacional Autónoma de México, Mexico City, Mexico.
- 03/2011 - 09/2011 **Mechanisms or neuronal death.** Internship at the Neurodevelopment and Physiology department (Prof. Julio Morán Andrade) of the Universidad Nacional Autónoma de México, Mexico City, Mexico.

- **SCIENTIFIC PUBLICATIONS:**

Original publication:

- 2018 Ott M¹, **Avendaño-Guzmán E**¹, Ullrich E, Dreyer C, Strauss J, Harden M, Schön M, Schön MP, Bernhardt G, Stadelmann C, Wegner C, Brück W, Nessler S. Quinoline-3-carboxamides utilize a CD155-mediated NK/DC interaction to suppress CNS autoimmunity. 2018 [in revision].
- 2014 **Avendaño-Guzmán E**, Bouter Y, Richard BC, Lannfelt L, Ingelsson M, Paetau A, Verkoniemi-Ahola A, Wirths O, Bayer TA.. Mol Neurodegener. 2014; 9: 13.

Poster presentations:

- 2017 **Avendaño-Guzmán E**, Ott M, Wegner C, Hayardeny L, Ullrich E, Schoen M, Brück W, Nessler S. Laquinimod is a potent aryl hydrocarbon receptor dependent activator of natural killer cells. American Academy of Neurology, Boston, 2017.
- 2016 **Avendaño-Guzmán E**, Barrette B, Theiss R, Lagumersindez - Denis N, Hayardeny L, Stadelmann-Nessler C, Nave KA, Brück W, Nessler S. A new rodent model of progressive demyelination and neurodegeneration mimicking progressive MS. 13th International Congress of Neuroimmunology, Jerusalem, 2016.
- 2015 **Avendaño-Guzmán E**, Stadelmann-Nessler C, Brück W, Nessler S. Evaluating the function of MOG specific-TCR CD8⁺ T cells in CNS autoimmunity. 6th biennial neuroscience conference Neurizons, Göttingen, 2015.
