

Insights into the biogenesis of the human mitochondrial ribosomal large subunit

–

Characterisation of mL44 and mL45

Dissertation

for the award of the degree

“Doctor rerum naturalium”
of the Georg-August-Universität Göttingen

within the doctoral program: Biomolecules: Structure-Function-Dynamics
of the Georg-August University School of Science (GAUSS)

submitted by

Elisa Hanitsch

from Lutherstadt Wittenberg

Göttingen, 2020

Members of the Thesis Committee

Dr. Ricarda Richter-Dennerlein (Supervisor and First Referee)	University Medical Center Department of Cellular Biochemistry Göttingen, Germany
Prof. Dr. Heike Krebber (Second Referee)	Georg-August University of Göttingen Institute for Microbiology and Genetics Department of Molecular Genetics Göttingen, Germany
Prof. Dr. Marina Rodnina (Third Referee)	Max Planck Institute for Biophysical Chemistry Department Physical Biochemistry Göttingen, Germany

Members of the Examination Board

Prof. Dr. Michael Meinecke	University Medical Center Department of Cellular Biochemistry Göttingen, Germany
Prof. Dr. Ralph Kehlenbach	University Medical Center Department of Molecular Biology Göttingen, Germany
Prof. Dr. Henning Urlaub	Max Planck Institute for Biophysical Chemistry Department Bioanalytical Mass Spectrometry Göttingen, Germany

Date of oral examination: 04th November 2020

Table 1: Abbreviations

A	Adenine
Å	Ångström
A260	Absorbance at 260 nm
ADP	Adenosine diphosphate
AF	assembly factor
Ala	Alanine
Aqua dest.	Aqua destillata
ArfB	Alternative ribosome-rescue factor B
Arg	Arginine
Arg	Arginine
A-site	Aminoacyl - site
Asn	Asparagine
Asp	Aspartic acid
ATP	Adenosine triphosphate
bp	Base pair(s)
BSA	Bovine serum albumin
C	Cytosine
CP	Central protuberance
Cryo-EM	Cryogenic electron microscopy
C-terminus	Carboxyl-terminus
Cys	Cysteine
Del	Deletion
Dig.	Digitonin
DMEM	Dulbecco's modified Eagle's medium
DNA	deoxyribonucleic acid
dNTP	2'-deoxynucleoside-5'-triphosphate
DRP1	Dynamin related protein 1
DTT	Dithiothreitol
Dup	Duplication
<i>E. coli</i>	<i>Escherichia coli</i>
EDTA	Ethylendiaminetetraacetic acid
ER	Endoplasmic Reticulum
E-site	Exit - site
EtOH	Ethanol
F	Fraction
FAD	Flavin adenine dinucleotide
FADH ₂	Reduced flavin adenine dinucleotide
FASTKD4	FAST kinase domain-containing protein 4
FCS	Fetal calf serum
Fe-S	Iron-sulfur
FIS1	Mitochondrial fission protein 1
fs	Frame shift
G	Guanine
gDNA	genomic DNA
GDP	Guanosine diphosphate
Gln	Glutamine
Glu	Glutamic acid
GTP	Guanosine triphosphate

h	Helix
<i>H. sapiens</i>	<i>Homo sapiens</i>
HEK293T	Human embryonic kidney cell line
HEPES	4-(2-hydroxyethyl)-1-piperazinethanesulfonic acid
His	Histidine
HSP	Heavy strand promoter
H-strand	Heavy strand
IBM	Inner boundary membrane
IMJ	Intermitochondrial junctions
IMM	Inner mitochondrial membrane
IP	Immunoprecipitation
kD	Kilo-Dalton
LB	Lysogeny broth
Leu	Leucine
LFQ	Label free quantification
LRPPRC	Leucine-rich pentatricopeptide repeat containing protein
LSP	Light strand promoter
L-strand	Light strand
LSU	Large subunit
Lys	Lysine
M	Crude mitochondria
MAM	Mitochondria-associated endoplasmic reticulum membrane
Mba1	Multi-copy bypass of AFG3 protein
MCU	Mitochondrial Ca ²⁺ uniporter
Met	Methionine
MetOH	Methanol
MFN	Mitofusin
MIA	Mitochondrial import and assembly machinery
MICOS	Mitochondrial contact site and cristae organizing system
MIM	Mitochondrial import complex
MPP	Mitochondrial processing peptidase
mRNA	Messenger ribonucleic acid
MRP	Mitoribosomal protein
mt	Mitochondrial
mtDNA	Mitochondrial deoxyribonucleic acid
mtEFG1	Mitochondrial elongation factor G
mtEFTu	Mitochondrial elongation factor Tu
MTERF1	Mitochondrial termination factor 1
MTFMT	Methionyl-tRNA formyltransferase
mtIF2	Mitochondrial initiation factor 2
mtIF3	Mitochondrial initiation factor 3
mtPAP	Mitochondrial polyA polymerase
mtRF1	Mitochondrial peptide chain release factor 1
mtRF1a	Mitochondrial peptide chain release factor 1-like
NCBI	National Center for Biotechnology Information
NCR	Non-coding region
NTD	N-terminal domain
N-terminal	Amino-terminal
OD	Optical density
OMM	Outer mitochondrial membrane
OPA1	Optic atrophy 1
OXPHOS	Oxidative phosphorylation system
P	Pellet

PAGE	Polyacrylamide gel electrophoresis
PAM	Presequence translocase-associated motor
PBS	Phosphate buffered saline
PCR	polymerase chain reaction
PDB	Protein Data Bank
Pdf	Peptide deformylase
PES	Polypeptide exit site
Phe	Phenylalanine
PK	Proteinase K
PMSF	Phenylmethylsulfonylfluoride
PNPase	Polynucleotide phosphorylase
POLRMT	Mitochondrial DNA-directed RNA polymerase
PPR	Pentatricopeptide repeat
Pro	Proline
P-site	Peptidyl - site
PTC	Peptidyl transferase centre
PVDF	Polyvinylidene fluoride
qMS	Quantitative mass spectrometry
RNA	ribonucleic acid
ROS	Reactive oxygen species
rpm	Rounds per minute
RRF	Ribosome recycling factor
rRNA	Ribosomal ribonucleic acid
<i>S. cerevisiae</i>	<i>Saccharomyces cerevisiae</i>
SAM	Sorting and assembly machinery
SDS	Sodium dodecyl sulfate
SILAC	Stable isotope labelling by amino acids in cell culture
siRNA	Small interfering ribonucleic acid
SLIRP	Stem-loop-interacting RNA binding protein
SN	supernatant
SSU	small subunit
T	Thymine
<i>T. brucei</i>	<i>Trypanosoma brucei</i>
TAE	Tris/acetate/EDTA buffer
TEFM	Transcription elongation factor
TFAM	Mitochondrial transcription factor A
TFB2M	Mitochondrial transcription factor B2
TIM	Translocase of the inner mitochondrial membrane
TOM	Translocase of the outer mitochondrial membrane
tRNA	Transfer ribonucleic acid
TRNT1	tRNA nucleotidyltransferase 1
U	Uracil
UTR	Untranslated region
v/v	Volume / volume
Val	Valine
VDAC	Voltage-dependent anion-selective channel
WT	Wild type

1. Abstract

Due to the presence of high-resolution cryo-EM structures of the human mitoribosome, the understanding about the function and assembly of the intriguing mitochondrial ribonucleoprotein complex increased tremendously during the last years. Even if the human mitoribosome descended from a bacterial ancestor, its structure and composition differs remarkably. During evolution, the RNA content decreased to approximately 50 % of the original bacterial. In contrast, many mitochondrial ribosome specific proteins were recruited and the existing proteins were extended leading to an inverted RNA to protein ratio. Many *in vitro* and *in vivo* studies about the assembly of the 70S bacterial ribosome have been conducted in the past. However, the assembly of the 55S human mitoribosome is not completely solved even if analyses about the biogenesis of the 54S subunit of *Saccharomyces cerevisiae* and the assembly of the mtLSU of *Trypanosoma brucei* contributed to our understanding. The number of mutations in genes encoding for proteins required for the mitochondrial translational apparatus which are implicated in severe early-onset diseases with various clinical phenotypes is growing. Hence, a deep understanding about the complex mechanisms of mitoribosomal assembly is required to shed light into the molecular basis leading to the manifestation of these severe human mitochondrial diseases.

Within this thesis, a new purification protocol was established to obtain 55S human mitoribosomes from HEK293T cells. Therefore, the separation of mitoribosomal complexes on sucrose gradients was optimised in regard of sucrose concentration, buffer conditions and purity of starting material. This was done to ensure a reasonable separation of 28S mtSSU, 39S mtLSU and 55S monosome from each other as well as to improve the stability of the before mentioned complexes. By using the established protocol, 55S human mitoribosomes were successfully isolated for future analyses of the assembly pathway.

In addition, to analyse the biogenesis of the 39S subunit, two proteins of the mtLSU were further characterised. The disease associated protein mL44 was shown to be crucial for *de novo* synthesis of mtDNA-encoded proteins as well as mtLSU assembly. Investigations using a FLAG-tagged variant of mL44 revealed that this protein is probably part of an early assembly intermediate together with bL20m and bL21m. Furthermore, by characterising mL45 it was observed that the mitoribosomal membrane anchor is required for functional mitochondrial translation and hierarchical assembly of the 39S mtLSU.

2. Introduction

2.1 Mitochondria

2.1.1 General aspects

During evolution two billion years ago, ancient eukaryotic cells engulfed α -proteobacteria (Friedman and Nunnari, 2014). Thus, a new organelle emerged: the mitochondrion. During evolution 99% of the genetic information encoded in the mitochondrial genome was outsourced to the nucleus (Richter-Dennerlein et al., 2015). Just 1 % is still encoded by the mitochondrial genome, which is located within the mitochondrial matrix. This innermost compartment is separated from the cytosol by an inner mitochondrial membrane (IMM) (Figure 1), inner membrane space (IMS) and outer mitochondrial membrane (OMM) (Wiedemann and Pfanner, 2017). Each compartment or membrane fulfils specialized functions within mitochondria.

Figure 1: Mitochondrial structure. Abbreviations not mentioned in the text: mitochondrial Ca^{2+} uniporter (MCU), inner boundary membrane (IBM). Picture taken from Giacomello et al., 2020. The OMM serves as a barrier to the cytosol, but small hydrophilic molecules are able to diffuse through voltage-dependent anion-selective channels (VDAC)/ porins as reviewed by Benz, 1994. In addition, it is a contact site to the endoplasmic reticulum (ER) via the mitochondria-associated endoplasmic reticulum membrane (MAMs) and to other mitochondria via intermitochondrial junctions (IMJ) (Cogliati et al., 2016; Rowland and Voeltz, 2012).

In contrast, the IMM is highly impermeable to most molecules. The IMM has a much higher protein content than the OMM and is characterized by the presence of a specific phospholipid: cardiolipin (Comte et al., 1976). The characteristic morphology of mitochondria is formed through invaginations of the IMM into cristae. The cristae junctions are mediated by the MICOS complex (mitochondrial contact site and cristae organizing system) and OPA1 (optic atrophy 1), whereas the apex of the cristae is built through dimerization of ATP-synthase complexes (Cogliati et al., 2016; Strauss et al., 2008). These cristae are specialized compartments where most of the respiratory chain complexes are situated (Cogliati et al., 2016).

Depending on the cell type, mitochondria display a variety of different shapes from tubular to spheroid (Bereiter-Hahn and Vöth, 1994). Regulated mitochondrial fusion and fission events are required for proper functionality of the organelle. MFN1 (mitofusin 1), MFN2 and OPA1 are players in mitochondrial fusion, whereas DRP1 (dynamin related protein 1) and FIS1 (mitochondrial fission protein 1) are components of the fission machinery (Chan, 2006).

2.1.2 Import of proteins

Due to the fact that the mitochondrial proteome comprises about 1000 proteins, an import of nuclear-encoded proteins across the mitochondrial double membrane layer is required. Depending on the properties and final destination of the protein to be imported, there are five different pathways currently described, but it is highly likely that there are more existing (Wiedemann and Pfanner, 2017). Four of them are using the translocase of the outer mitochondrial membrane (TOM complex) for translocation of proteins across the OMM.

Presequence pathway: Many mitochondrial proteins are synthesized in the cytosol as precursor proteins, containing mostly cleavable N-terminal presequences. Receptors of the TOM complex recognize these presequences due to their positively charged amphipathic α -helical properties. The preproteins are translocated via the OMM and handed over to the presequence translocase of the inner membrane (TIM23 complex). If a stop transfer signal is present within the cargo, the protein is inserted into the IMM. Otherwise the preprotein is transferred to the presequence translocase-associated motor (PAM), which facilitates the final import into the matrix under ATP consumption, where the mitochondrial processing peptidase (MPP) cleaves off the presequence (Callegari et al., 2020; Harbauer et al., 2014; Schulz et al., 2015; Wiedemann and Pfanner, 2017).

Carrier pathway. Hydrophobic inner membrane carrier proteins containing non-cleavable presequences within the mature protein are imported via the carrier pathway. After translocation via the TOM complex, the proteins are further transported across the IMS by small TIM

chaperones and inserted into the IMM by the TIM22 complex using membrane potential (Rehling et al., 2003; Wasilewski et al., 2017).

β -barrel pathway. β -barrel protein precursors are translocated via the TOM complex, handed over to small TIM chaperones within the IMS and inserted into the OMM by the sorting and assembly machinery (SAM) (Harbauer et al., 2014; Paschen et al., 2003; Wiedemann and Pfanner, 2017).

MIA pathway. Cysteine-rich IMS proteins are imported via the MIA pathway. Therefore, unfolded reduced precursor proteins are imported by the TOM complex and further processed by the mitochondrial import and assembly (MIA) machinery, which inserts disulphide bonds for proper folding (Harbauer et al., 2014).

MIM pathway. The import of α -helical transmembrane proteins of the OMM is not completely solved until now, but it was suggested that these proteins do not use the TOM complex but rather the mitochondrial import complex (MIM) (Harbauer et al., 2014).

2.1.3 Function of mitochondria

Mitochondrial function within eukaryotic cells is diverse as they contribute to Ca^{2+} signalling (Clapham, 2007), ROS production (Shadel and Horvath, 2015), amino acid biosynthesis and biogenesis of lipids. Various pathways of apoptosis are triggered by mitochondria. Amongst them are different mechanisms as: a) release of cytochrome *c* as caspase activator, b) change of redox potential and c) alteration of electron transport and disruption of oxidative phosphorylation system (Green and Reed, 1998). In addition, mitochondria are essential for Fe/S protein and heme biogenesis (Lill and Mühlenhoff, 2008). Several metabolic pathways are situated within the mitochondrial matrix such as the Krebs cycle, urea cycle and β -oxidation.

However, mitochondria are best known for their role in ATP production. As mitochondria are termed “powerhouse of the cell”, their main function is to supply the cell with energy. NADH and FADH_2 are generated within glycolysis, citric acid cycle and β -oxidation. In order to produce energy in form of ATP by oxidative phosphorylation (OXPHOS), those molecules are oxidized by the respiratory chain complex I and II in the inner mitochondrial membrane. Movement of electrons along the complexes I – IV is linked to pumping of protons from the matrix into the IMS by complex I, III and IV leading to an electrochemical gradient. The driving force of this membrane potential is utilized by the fifth OXPHOS complex to produce ATP (Hosler et al., 2006; Saraste, 1999; Winge, 2012).

The NADH dehydrogenase complex is the first and biggest complex within the OXPHOS system, consisting of 38 nuclear and 7 mtDNA-encoded proteins (Brandt, 2006). Through oxidation of NADH two electrons are transferred to ubiquinone and 4 protons are pumped from the matrix to the IMS. The succinate dehydrogenase (complex II), also part of the citric acid cycle, is the smallest complex within the electron transport chain consisting of just four proteins (Bezawork-Geleta et al., 2017). It catalyses the oxidation of succinate to fumarate and the subsequent transfer of 2 electrons to ubiquinone. The cytochrome *c* reductase (complex III) passes electrons from ubiquinol to cytochrome *c* coupled with a proton transfer across the membrane in a process called the Q-cycle (Saraste, 1999). The fourth and final complex of the electron transport chain is called cytochrome *c* oxidase, which reduces molecular oxygen into water by concomitant pumping of one proton per transferred electron across the IMM (Saraste, 1999). The ATP synthase (complex V) is part of the OXPHOS complex but not of the respiratory chain. Upon flow of protons through the channel of complex V, ATP is produced (Walker, 2013).

Figure 2: Components of the oxidative phosphorylation system are of dual genetic origin (besides complex II). Most of the proteins are encoded in the nucleus, expressed by 80S cytosolic ribosomes and imported via TOM and TIM complexes. Core components of OXPHOS are still expressed within mitochondria. Numbers above the complexes depict the amount of nuclear and mitochondrial encoded proteins. Picture adapted from (Hanitsch and Richter-Dennerlein, 2020).

The majority of components of the OXPHOS complexes are encoded within the nucleus and transported into mitochondria (Figure 2). Nevertheless, some proteins are expressed within mitochondria (complex I: ND1, ND2, ND3, ND4, ND4L, ND5, ND6, complex III: CYTb, complex IV: COX1, COX2, COX3 and complex V: ATP6, ATP8). One assumption was that the genetic information of these 13 proteins was not transferred to the nucleus due to their high hydrophobicity. In

addition, rRNA components and tRNAs required for final protein expression are also still encoded on the mtDNA. Transport of very hydrophobic protein cargos molecules would be challenging for the cell. For this reason, it was hypothesized that the genetic information of some OXPHOS proteins and parts of the gene expression machinery was maintained within mitochondria during evolution (Kehrein et al., 2013).

2.1.4 Mitochondrial gene expression

2.1.4.1 Mitochondrial genome

Depending on the type of tissue there is a great variance of mtDNA copy number spanning from 1×10^5 (human oocytes) to 3×10^3 (human fibroblasts) (Chen et al., 1995; Hällberg and Larsson, 2014; Kukat et al., 2011). The mtDNA is organized within nucleoids – clusters of DNA and protein, which are closely associated to the IMM (Brown et al., 2011). Per nucleoid just one copy of mtDNA together with the main packaging factor TFAM (mitochondrial transcription factor A) was found to be present (Kukat et al., 2011).

The mitochondrial genome itself is composed of a 16.5 kb-sized circular DNA molecule consisting of a heavy (H) and a light (L) strand. Historically, these terms are used due to the fact that one strand has a high guanine content, which leads to a separation of the strands by CsCl_2 gradient ultracentrifugation (Berk and Clayton, 1974; Borst, 1972; Gustafsson et al., 2016). The H-strand contains most of the genetic information as it encodes for 2 rRNAs, 14 tRNAs and 8 monocistronic and 2 bicistronic mRNAs giving rise to 12 proteins. On the L-strand, just 1 mRNA and 8 tRNAs are encoded (Figure 3) (Anderson et al., 1981; Ott et al., 2016).

Figure 3: Mitochondrial genome and transcripts. mtDNA consists of H- and L-strand. The mt genome encodes for 22 tRNAs, 2 rRNAs and 11 mRNAs. Just one longer non-coding region (NCR) is present containing regulatory sequences. The transcripts have nearly no 5' untranslated region (UTR) and also no 7-methylguanosine cap. All mRNAs, besides ND6, have a short polyA tail. Just ND5, ND6, CO1,

and CO2 contain a short UTR before their 3' end. Picture adapted from (Hällberg and Larsson, 2014; Richter-Dennerlein et al., 2015).

Codon usage in mitochondria differs from the universal genetic code. Besides AUG, AUA encodes for methionine (Barrell et al., 1979). In addition, AUU also codes for methionine during initiation, but codes for isoleucine during elongation (Fearnley and Walker, 1987). UGA decodes for tryptophan, instead of being a termination codon (Barrell et al., 1979). Furthermore, AGA and AGG do not code for arginine and provoke a -1 ribosomal frameshift leading to the termination of ND6 and COX1 in the stop codon UAG (Temperley et al., 2010a).

2.1.4.2 Transcription and post-transcriptional modifications

Transcription of mtDNA takes place within nucleoids (Pearce et al., 2017). For each strand of the mtDNA exists one promoter: HSP and LSP (Hällberg and Larsson, 2014; Terzioglu et al., 2013). Each of them gives rise to one transcript which has to be further processed. For transcription initiation, the DNA-dependant RNA polymerase POLRMT requires help from other factors in contrast to other structurally related RNA polymerases (D'Souza and Minczuk, 2018). First, TFAM needs to associate with the mtDNA, bends the DNA and recruits POLRMT to the promoter region building the closed pre-initiation complex (Gustafsson et al., 2016; Hillen et al., 2017a; Ramachandran et al., 2017). Next, the mitochondrial transcription factor B2 (TFB2M) binds to POLRMT and melts the initiation region of the promoter, creating the open initiation complex and allowing the polymerase to start transcription (Hillen et al., 2017a; Ramachandran et al., 2017). In order to allow transcription elongation, TFB2M is released and the transcription elongation factor (TEFM) is bound to POLRMT, enhancing its processivity (Hillen et al., 2017b; Minczuk et al., 2011). If transcription is finished, POLRMT and TEFM are released from the mtDNA (Hillen et al., 2017b). However, transcription termination initiated by HSP remains still unsolved, whereas LSP transcription is terminated by binding of the mitochondrial termination factor 1 (MTERF1) (Hillen et al., 2018).

Due to just two promoter areas existing within the mitochondrial genome, there are only two resulting polycistronic transcripts. Besides Cytb/ND5 and ATP6/COIII, all rRNA and protein coding areas are separated by tRNAs (Figure 3). Already in 1981 it was proposed with the "tRNA Punctuation Model" that endonucleolytic cleavage excises the tRNAs and thereby releases the other mRNAs and rRNAs (Ojala et al., 1981). Cleavage of the polycistronic transcript is carried out by mitochondrial RNase P at the 5' end of tRNAs, followed by a cleavage at the 3' end by RNase Z (ELAC2) (Hällberg and Larsson, 2014). Nevertheless, as not all mRNAs are flanked by tRNAs, their release cannot be explained by the aforementioned model and is still subject of ongoing research (D'Souza and Minczuk, 2018).

After release of mRNAs from the polycistronic transcript, 10 of 11 mRNAs are polyadenylated by mitochondrial polyA polymerase (mtPAP) (Hällberg and Larsson, 2014; Nagaike et al., 2005; Tomecki et al., 2004). Polyadenylation is required to stabilize specific mRNAs or to destabilize other ones. In addition, seven mRNAs do not contain a complete stop codon. Their open reading frame is completed by addition of the poly-A tail (Temperley et al., 2010b). Another player in enhancing mt mRNA stability is the leucine-rich pentatricopeptide repeat (PPR)-containing protein (LRPPRC). LRPPRC acts in a complex together with the stem-loop-interacting RNA-binding protein (SLIRP) (Sasarman et al., 2010). Upon blockage of polynucleotide phosphorylase (PNPase) and the helicase SUV3, this complex prevents mRNA from being degraded and stimulates mtPAP for further polyadenylation of mRNAs (Chujo et al., 2012; Ruzzenente et al., 2012). Also FASTKD4 (FAST kinase domain-containing protein 4) modulates mRNA stability in some cases (Wolf and Mootha, 2014).

Mitochondrial tRNAs undergo a variety of post-transcriptional modifications to become fully functional. A complete list of all known factors was summarized by Suzuki and Suzuki, 2014. In brief, the nucleotides of tRNAs are chemically modified and the CCA trinucleotide is added to the 3' end of all mt tRNAs by TRNT1 (tRNA nucleotidyltransferase 1) (Nagaike et al., 2001; Suzuki et al., 2011). Following this addition, tRNAs are ready to be charged with their respective cognate amino acid by aminoacyl-tRNA synthetases (Hällberg and Larsson, 2014). In total, the 22 tRNA recognize 60 sense codons (Suzuki et al., 2011). In mitochondria, just one tRNA is available to decode methionine codons during initiation and elongation in contrast to two distinct cytosolic tRNA^{Met}. It was reported that formylation of a cytosine residue at the wobble position (f⁵C34) of the specific tRNA contributes to recognition of all three codons (AUG, AUU, AUA) (Bilbille et al., 2011). Later in translation, Met-tRNA^{Met} is used during elongation. A subset of Met-tRNA^{Met} is formylated by mitochondrial methionyl-tRNA formyltransferase (MTFMT) and subsequently recruited during translation initiation (Tucker et al., 2011).

The rRNA molecules also undergo excessive post-transcriptional modifications. This will be described in chapter 2.2.2.1. Most of the post-transcriptional processing events of mRNAs, tRNAs and rRNAs are suggested to take place within mitochondrial granules, located in close proximity of nucleoids (Ott et al., 2016).

2.1.4.3 Translation and translational regulation

Translation on mitoribosomes can be divided into four distinct steps (initiation, elongation, termination, ribosome recycling), each requiring a specific subset of regulation factors (Figure 4). Translation initiation in mammalian mitochondria requires the presence of two initiation factors (mtIF2 and mtIF3) instead of three as in bacteria (IF1, IF2, IF3). Detailed mechanisms of translation initiation in mitochondria were revealed by cryo-EM (Koripella et al., 2019; Kummer et al., 2018). In the beginning, mtIF3 binds to 28S mtSSU. In presence of mRNA, a conformational change takes place, to allow binding of fMet-tRNA^{Met}-mtIF2^{GTP} forming the initiation complex. If no mRNA is present, mtIF3 bound to mtSSU blocks association with this complex and the mtLSU (Koripella et al., 2019).

The mRNA binds in proximity of the mitoribosomal PPR protein mS39 located at the entrance of mt mRNA-channel (Amunts et al., 2015; Greber et al., 2015). Another mitoribosomal protein, uS5m, assists to place the mRNA to the aminoacyl (A) and peptidyl (P) site. mtIF2 specifically recognizes fMet-tRNA^{Met} and supports its binding to mtSSU. Upon correct anticodon binding in the P-site, the 39S mtLSU joins, promoted by the mtLSU protein bL12m (Kummer et al., 2018). Association of the mtLSU encourages hydrolysis of GTP to GDP within mtIF2 and the initiation is completed (Kummer et al., 2018). mtIF2^{GDP} and mtIF3 are released concomitantly (Mai et al., 2017). However, very recently a distinct mechanism of translation initiation was proposed by Khawaja et al. They suggested, if mtIF3 is associated with the 28S mtSSU, binding of the initiator tRNA is inhibited. By accommodating mtIF2^{GTP}, mtLSU is recruited, mtIF3 is released and replaced by fMet-tRNA^{Met}. Association of the mRNA was described as final step, which is completely different from the bacterial ancestor of the mitoribosome (Khawaja et al., 2020). Future analyses need to provide evidence for which pathway is more likely to occur.

Before translation elongation can proceed, the N-terminal tail of mL45 has to be removed from the polypeptide exit tunnel in order to enable the growing peptide chain to leave the mitoribosome (Koripella et al., 2020; Kummer et al., 2018). Cryo-EM studies revealed a conformational change of mL45 between initiation and elongation stage, suggesting that this is necessary to anchor the mitoribosome to the inner mitochondrial membrane (Koripella et al., 2020).

Figure 4: Mitochondrial Translation. Picture adapted from Mai et al., 2017 including initiation steps described by Koripella et al., 2019; Kummer et al., 2018.

Translation elongation continues upon binding of a complex consisting of mtEFTu coupled with GTP and an aminoacylated tRNA to the A -site of the 55S ribosome. If the anticodon of the tRNA matches the codon presented from the mRNA in the A -site, GTP is hydrolysed and mtEFTu^{GDP} is released. The ribosome catalyses the peptide bond formation between the newly entered aminoacylated tRNA present in the A -site and the peptide chain coming from the P -site. The prolonged peptide chain is now situated in the A -site and the P -site tRNA is deacylated. Upon

binding of mtEFG1^{GTP}, the deacylated tRNA is released to the E -site and the tRNA coupled with the peptide chain fills the P -site, leaving the A -site empty (Hällberg and Larsson, 2014). A specific structure of the mtLSU called the P -site finger supports correct tRNA positioning in the A - and P -site (Greber et al., 2015). To restore the activity of mtEFTu, it builds a complex with mtEFTs, which facilitates dissociation of GDP. Upon association of GTP, mtEFTs is released and mtEFTu^{GTP} is available for the next elongation cycle (Cai et al., 2000).

As reviewed by Chrzanowska-Lightowlers, 2011, this mechanism proceeds until a stop codon encoded on the mRNA reaches the A -site. As there is no matching tRNA, a termination factor binds to release the nascent polypeptide. The termination factor recognizes the stop codon in the A -site by the tripeptide motif (PXT motif) and the α -helical tip. This leads to a conformational change of domain 3 of the termination factor leading to the translocation of the GGQ motif into the peptidyl transferase centre. This enables the release factor to facilitate the hydrolysis of the ester bond between the peptidyl tRNA and the nascent peptide chain (Chrzanowska-Lightowlers et al., 2011). Four release factors have been identified in human mitochondria: mtRF1, mtRF1a, ICT1 (mL62) and C12orf65 (D'Souza and Minczuk, 2018; Huynen et al., 2012; Lind et al., 2013; Richter et al., 2010; Soleimanpour-Lichaei et al., 2007). The question, why the mitoribosome affords four factors for one purpose is subject of still ongoing research.

For recycling of the mitoribosome after translation, the binding of mtRRF and mtEFG2^{GTP} is required. The complex of mtRRF-mtEFG2^{GTP} splits the 55S ribosome into 28S and 39S and releases the mRNA as well as the deacylated tRNA (Rorbach et al., 2008; Tsuboi et al., 2009). GTP consumption and mtIF3 are necessary to dissociate the before mentioned factors from the 39S LSU (Tsuboi et al., 2009).

All of the proteins synthesized from 55S ribosome are highly hydrophobic membrane proteins. For this reason, it is necessary that the newly synthesized polypeptides are released in close proximity of the IMM (Mai et al., 2017) or even co-translationally (Richter-Dennerlein et al., 2015). Therefore, it was suggested that the translational apparatus needs to be situated close to the IMM. By cryo EM tomography it was shown that the mitoribosomal protein (MRP) mL45 mediates this contact between 55S and IMM (Englmeier et al., 2017). Nevertheless, insertion of the synthesized proteins into the IMM is not completely understood in the mammalian system. In yeast, the translocase Oxa1 was described to serve this purpose amongst others (Mai et al., 2017; Stiller et al., 2016). In mammals, OXA1L is the homologue of the yeast Oxa1 and was hypothesized to fulfil this function (Haque et al., 2010). Until now, only an interaction of OXA1L to the 55S ribosome has been shown (Mai, 2016), but functional studies and the concrete interaction partner within the mitoribosome are still missing.

Since proteins of the OXPHOS complexes are of dual genetic origin, a tight regulation of mitochondrial and cytosolic translation is required. For the assembly of cytochrome *c* oxidase, it was shown if COX4 (first nuclear encoded protein to bind in complex IV assembly) is missing, translation of COX1 (mtDNA-encoded) is stalled. Thereby, mt translation is regulated by the presence of nuclear encoded subunits (Richter-Dennerlein et al., 2016). Another feedback mechanism was described for complex I biogenesis, as the nuclear encoded MITRAC15 regulates ND2 expression within mitochondria (Wang et al., 2020). Moreover, factors to regulate cytosolic translation were found to act as well in mitochondria. miR-1 bound to the mt mRNA together with AGO2 stimulates mt translation (Zhang et al., 2014). This was surprising due to the fact that the microRNA miR-1 acts in the cytosol together with AGO2 and GW182 as translational silencing factors and also mediates mRNA degradation (Czech and Hannon, 2011). Future research on mt translation regulation will most likely reveal more regulation pathways.

2.2 Mitochondrial Ribosome

2.2.1 Structure of 55S mitoribosome

The mitochondrial 55S mitoribosome consists of two individually shaped subunits like all ribonucleoprotein complexes termed ribosomes. It is composed of a 39S mt large subunit (LSU) and a 28S mt small subunit (SSU) (O'Brien, 1971). In 2003, a first structure of the mitoribosome at 13.5 Å was published and revealed tremendous differences to the bacterial ribosome as well as the eukaryotic cytosolic ribosome (Sharma et al., 2003) (see Table 2).

Table 2: Overview of ribosomal properties. Table adapted from (Greber and Ban, 2016)

	Bacteria (<i>Escherichia coli</i>)	Eukaryotic cytosol	Yeast mitochondria	Mammalian mitochondria
Ribosome	70S	80S	74S	55S
Molecular weight	2.3 MDa	3.3-4.3 MDa	3-3.3 MDa	2.7 MDa
rRNAs	3	4	2	2 + 1 tRNA
Proteins	54	79-80	82	82
Large subunit	50S	60S	54S	39S
rRNAs	23S/5S	26-28S/5.8S/5S	21S	16S + tRNA ^{Phe} /tRNA ^{Val}
Proteins	33	46-47	46	52
Small subunit	30S	40S	37S	28S
rRNAs	16S	18S	15S	12S
Proteins	21	33	36	30

As mitochondria evolved from a bacterial ancestor, the same is true for the mitochondrial ribosome. It was suggested, that the mitoribosomal evolution happened within two phases: a constructive and a reductive phase. First, mitoribosome-specific proteins were recruited in order to compensate for mutations in mtDNA encoded rRNAs. During the second phase, the rRNA content was reduced (Van Der Sluis et al., 2015). Therefore, the rRNAs of the mitoribosome were reduced to approximately 50 % of the bacterial rRNAs (reviewed by O'Brien, 2003). Shortening of rRNAs happened in all domains, distributed across the complete mitoribosome (Brown et al., 2014). In contrast, the protein content increased by incorporation of specific mitoribosomal proteins and extensions of proteins having homologues in bacteria. Hence, the rRNA core of the mitoribosome is nearly completely covered by proteins (Figure 5) (Amunts et al., 2015; Bieri et al., 2018; Brown et al., 2014; Sharma et al., 2003).

Figure 5: Proteins of the human 55S ribosome. Conserved proteins of 70S and 55S are depicted in blue. Homologous proteins with extensions are shown in yellow and mitoribosome-specific proteins are visualized in red. rRNA is shown in grey. Picture taken from Amunts, A., Brown, A., Toots, J., Scheres, S.H.W., and Ramakrishnan, V. (2015). The structure of the human mitochondrial ribosome. *Science* (80). 348, 95–98. Reprinted with permission from AAAS. DOI: <https://doi.org/10.1126/science.aaa1193>

The 36 mitoribosomal-specific proteins do not only protect the RNA but also display various other functions, which will be described later (Amunts et al., 2015; Bieri et al., 2018; Greber et al., 2015). As a result of the RNA compression and protein acquisition, the RNA to protein ratio was inverted between bacterial ribosomes and mitoribosomes (Sharma et al., 2003). Only a small number of the recruited proteins stabilize the 55S ribosome by compensating for the rRNA loss leading to a more porous architecture of the mammalian mitoribosome (Brown et al., 2014; Sharma et al., 2003). Most of the mitoribosomal-specific proteins are clustered around the existing core as described by the onion shape model of the ribosome (Hsiao et al., 2009; Petrov et al., 2019). Due to this structure, the mitoribosome has a lower sedimentation coefficient than its bacterial counterpart even though it has a greater molecular mass (Sharma et al., 2003).

2.2.1.1 Structure of the 39S mtLSU

The 39S mtLSU consists of 52 nuclear encoded mitoribosomal proteins and a 16S rRNA (as reviewed by Bieri et al., 2018). The 50S bacterial LSU contains a 5S rRNA as core structure in the central protuberance (CP), which is absent in mitoribosomes (O'Brien, 2003). In 2014, the Ban and the Ramakrishnan group published high-resolution structures of the porcine and human mtLSU at 3.4 Å resolution. These structures revealed tRNA molecules as architectural features within the CP of the 39S LSU to compensate for the loss of the 5S rRNA (Brown et al., 2014; Greber et al., 2014a). In the human structure, tRNA^{Val} was found to be present (Brown et al., 2014) in contrast to the porcine structure where tRNA^{Phe} was identified (Greber et al., 2014a). Just these two tRNAs were described to be incorporated into mitoribosomes of different species, as they are

flanking the 12S and 16S rRNA genes (Anderson et al., 1981; Rorbach et al., 2016). Upon loss of tRNA^{Val} it was described that the mitoribosome is able to switch to tRNA^{Phe} (Rorbach et al., 2016).

In 70S bacterial and 80S cytosolic ribosomes, the CP is built around the 5S rRNA (Greber and Ban, 2016). The 74S yeast mitoribosome does not contain an additional structural RNA element in the CP besides its 21S rRNA (Amunts et al., 2014). Even if the central protuberance of mammalian mitoribosomes is completely remodelled, it maintained its functions to interact with the head of the 28S mtSSU and to tRNAs in the intersubunit space (Brown et al., 2014). During evolution, uL5 and bL25 were lost from the 39S mtLSU CP most likely due to the absence of the 5S rRNA (Brown et al., 2014; Petrov et al., 2019). The structural tRNA is stabilized within the CP via uL18m and bL31m (proteins with bacterial homologues) as well as by mL38, mL40 and mL48 (Figure 6) (Bieri et al., 2018; Brown et al., 2014). The connection of the CP to the body of the 39S is mediated through mL62 (ICT1), mL52 and mL64 (CRIF1) (Brown et al., 2014).

Figure 6: Structure of the remodelled CP in mammalian mitoribosomes. Picture taken from Bieri et al., 2018. Reprinted from *Current Opinion in Structural Biology*, 49, Bieri, P., Greber, B.J., and Ban, N., *High-resolution structures of mitochondrial ribosomes and their functional implications*, 44-53, Copyright (2018), with permission from Elsevier. DOI: <https://doi.org/10.1016/j.sbi.2017.12.009>

tRNAs are bound during mt translation at the respective A-, P- or E -site located in the intersubunit space between LSU and SSU. In the past, the presence of an E -site within mitoribosomes was long subject of debates (Mears et al., 2002; Sharma et al., 2003). However, the structures published by the Ban and Ramakrishnan laboratories are showing that the ribosomal E -site is preserved (Brown et al., 2014; Greber et al., 2014a). The tRNA binding sites had to co-evolve together with the highly variable mitochondrial tRNAs (Bieri et al., 2018). Characteristic structures of tRNA binding sites in bacteria are absent in the 55S ribosome. In detail, bL25 and helix H38 of the 16S rRNA are missing at the A -site and uL5 and helix H84 at the P -site (Brown et al., 2014). To stabilize tRNAs located in A - and P -site, the mitoribosome evolved a new structural element: the P -site finger. The P -site finger is a structure protruding from the CP reaching to the A - and P -

site tRNAs (Greber and Ban, 2016). It was hypothesized that mL40 and mL48 are structural components of the P-site finger (Greber et al., 2014a). Even so, additional evidence is required to prove this assumption.

Figure 7: Polypeptide exit tunnel of mammalian 55S mitoribosome. Picture adapted from (Bieri et al., 2018). Reprinted from *Current Opinion in Structural Biology*, 49, Bieri, P., Greber, B.J., and Ban, N., *High-resolution structures of mitochondrial ribosomes and their functional implications*, 44-53, Copyright (2018), with permission from Elsevier. DOI: <https://doi.org/10.1016/j.sbi.2017.12.009>

One evolutionary conserved structure within the 39S mtLSU is the peptidyl transferase centre (PTC) which is mainly formed by the 16S rRNA (Petrov et al., 2019) and bL27m (Greber et al., 2014a) similar to the bacterial ribosome. The highly diverged polypeptide exit tunnel reaches from the PTC to the polypeptide exit site (PES) and was adapted during evolution to the hydrophobic translational products of the mitoribosome (Figure 7). In contrast to the 74S yeast ribosome, the exit tunnel in mammalian mitoribosomes resembles the bacterial one (Amunts et al., 2014; Bieri et al., 2018). Nevertheless, the exit tunnel of the 55S ribosome is prolonged because of the addition of mitochondrial-specific ribosomal proteins or extension of ribosomal proteins (reviewed by Bieri et al., 2018). The tunnel wall comprises hydrophobic residues mostly by uL22m (Brown et al., 2014). The absence of the two rRNA structures (h7 and h24) found in bacteria was compensated by adaptations of uL24m and uL29m, leading to a more protein-rich structure (Brown et al., 2014). The tunnel exit is formed by the conserved proteins uL23m, uL29m, uL22m, uL24m and bL17m as well as by the mitochondria-specific proteins mL39, mL44 and mL45 (Figure 8) (Bieri et al., 2018; Brown et al., 2014; Greber et al., 2014b). As already described, the MRP mL45 mediates the contact between the IMM and the mitoribosome. This contact is most likely built through the helices h2 (S101-K114) and h3 (V116-S128) of mL45 (Englmeier et al., 2017).

Figure 8: Comparison of bacterial (*E. coli* PDB 4YBB) and human mitoribosomal (PDB 3J9M) mRNA tunnel entrance site and polypeptide exit site. Asterisks indicate respective tunnel entrance/exit. Green = mtSSU, blue = mtLSU. Picture taken from Mai et al., 2017.

Another feature of the 39S mtLSU is the L7/L12 stalk, which is also larger compared to its bacterial ancestor due to the acquisition of additional ribosomal proteins (Sharma et al., 2003). At this stalk, translational factors bind and GTP is hydrolysed (Brown et al., 2014). In bacteria, L10, L11 and several copies of L12 cluster around h42-44 of the 23S rRNA (Kavran and Steitz, 2007). Within the mitoribosome, homologue proteins are bound around the h42 and h43 of the 16S rRNA (Brown et al., 2014). Additionally, mL53, mL66, uL16m and mL63 are recruited, leading to a less flexible structure (Brown et al., 2014).

2.2.1.2 Structure of the 28S mtSSU

The 28S mtSSU comprises a 12S rRNA and 30 ribosomal proteins (14 mitochondria specific). During translation initiation, the mRNA is bound by the mtSSU and gated through the mRNA channel. This mRNA channel was extensively remodelled during evolution. The bacterial mRNA entrance is characterized by a ring-like structure formed out of uS3, uS4 and uS5 (Figure 8). uS4 is missing in human mitoribosomes as well as the C-terminal domain of uS3. The 28S mRNA entrance side is mainly built by uS5m, which also accoutres the channel with its basic and aromatic residues. However, just single stranded RNA molecules are able to pass the channel even though it was widened during evolution (Amunts et al., 2015). Comparable to cytosolic ribosomes, the 3' end of the 12S rRNA is not involved in translation initiation due to the loss of the Shine-Dalgarno sequence from mitochondrial transcripts (Montoya et al., 1981). Instead, the 3' end interacts with mS37. At the exit of the tunnel, bS1m is situated similar to bacteria, probably supporting mRNA binding (Amunts et al., 2015). In addition, uS7m, uS11m, bS18m and bS21m have been described to be located at the tunnel exit (Figure 9) (Greber et al., 2015).

Figure 9: Structure of mtSSU. Proteins enclosing mRNA tunnel exit are labelled. Picture adapted from Bieri et al., 2018. Reprinted from *Current Opinion in Structural Biology*, 49, Bieri, P., Greber, B.J., and Ban, N., High-resolution structures of mitochondrial ribosomes and their functional implications, 44-53, Copyright (2018), with permission from Elsevier.

DOI: <https://doi.org/10.1016/j.sbi.2017.12.009>

The decoding centre, located within the mtSSU, is entirely built by rRNA as it was shown for bacterial and yeast mitochondrial ribosomes (Amunts et al., 2015; Bieri et al., 2018; Desai et al., 2017; Greber et al., 2015). Therefore, it was hypothesized that decoding was preserved within different species (Greber et al., 2015).

High resolution cryo-EM analyses of the mtSSU revealed that the GTP binding protein mS29 is an integral part of its structure (Amunts et al., 2015; Greber et al., 2015). It is located at the head of the mtSSU and contacts CP proteins via the intersubunit bridges mB1a and mB1b (Figure 6). In total, three protein-protein and six protein-RNA intersubunit bridges mediate the contact between the two ribosomal subunits (Amunts et al., 2015). As these interactions are mainly

situated in the centre of both subunits and are less extensive than in bacteria, the mammalian mitoribosome exhibits a much more flexible structure than its bacterial counterpart (Greber et al., 2015).

2.2.2 Assembly of the 55S mammalian mitoribosome

2.2.2.1 Lessons from the bacterial ancestor

First studies about the assembly of the 70S bacterial ribosome were carried out under harsh ionic conditions and high temperatures (Shajani et al., 2011). Traub and Nomura, 1968, were able to show that a functional 30S SSU can be reconstituted *in vitro* out of synthesized rRNA and purified proteins. By investigating the order of protein addition, they proposed an assembly map based on thermodynamic binding dependencies. A similar approach for the 50S bacterial LSU was carried out by Nierhaus and Dohme, 1979 (Figure 10).

Figure 10: Assembly of the bacterial 30S SSU and 50S LSU *in vitro*. A) 30S SSU assembly based on thermodynamic binding dependencies described by Nomura. Primary binding proteins (1°) interact directly with the 16S rRNA and are incorporated first, followed by binding of secondary binding proteins (2°), which require interaction with 1°-binders, but not with the rRNA. Last, tertiary binding proteins (3°) are incorporated. Depending on the binding site on the rRNA (red: 5' domain, green: central domain, blue: 3' domain) the ribosomal proteins are ordered. B) 50S LSU assembly visualized by the thermodynamic dependency studies of Nierhaus. Similar to A), proteins are depicted on the map based on their binding position on the 23S rRNA. Proteins required for 5S rRNA binding are situated within the orange triangle. Picture taken from Shajani et al., 2011. Republished with permission of Annual Reviews, Inc. from *Assembly of bacterial ribosomes*. Shajani, Z., Sykes, M.T., and Williamson, J.R., *Annu. Rev. Biochem.* 80, 501–526. (2011); permission conveyed through Copyright Clearance Center, Inc. DOI: <https://doi.org/10.1146/annurev-biochem-062608-160432>

Nevertheless, even if these *in vitro* data were the basis for later research on bacterial ribosome assembly, *in vivo* studies were required to understand the biogenesis under physiological conditions. One of the striking differences evident from *in vivo* data was that the rRNA assembly occurs in a co-transcriptional manner. In addition, many biogenesis factors are required for the

assembly of the bacterial ribosome *in vivo* (reviewed by Davis and Williamson, 2017). The latest assembly map of the 70S was published by Chen and Williamson (2013) using a quantitative mass spectrometry approach. Since then, structures of assembly intermediates obtained by cryo-EM contributed to nowadays understanding of the process.

However, as the structure and composition of the 55S mammalian mitoribosome differs from its ancestor and also from other eukaryotic ribosomes, the knowledge gained about their biogenesis is not directly transferable to draw conclusions about the assembly of the 55S, especially for the 36 MRPs without homologs in bacteria (Greber and Ban, 2016). During the past years, a lot of new insights into the assembly of the 55S mitoribosome have been gained. It was hypothesized that the assembly occurs in a co-transcriptional manner within nucleoids and RNA granules (Antonicka and Shoubridge, 2015; Bogenhagen et al., 2014; Rackham et al., 2016). Factors to orchestrate the hierarchical incorporation of proteins into the growing particle were identified as well as modifying enzymes. In 2018, a first assembly map for the 39S and 28S was published by the laboratory of Bogenhagen.

2.2.2.2 Assembly factors

Many factors are required to assemble and mature the complex structure of the mammalian 55S mitoribosome (Figure 11). After excision of 12S and 16S rRNA from the primary transcript, mt rRNAs undergo modifications as base methylations, pseudouridylations and 2'-O-ribose methylations to complete their functionality and to enhance their stability. However, these modifications are less abundant in the mt rRNA than in bacterial and cytosolic ribosomes (De Silva et al., 2015).

Within the 12S rRNA, two adenines are di-methylated by the methyltransferase TFB1M at position 936 and 937 (Liu et al., 2019; Seidel-Rogol et al., 2003) and two cytosine residues (C839 and C841) are methylated by METTL15 (Chen et al., 2020; Van Haute et al., 2019; Laptev et al., 2020) and NSUN4 (Metodieiev et al., 2014), respectively. In addition, TRMT2B methylates one uridine residue at position 429 (Powell and Minczuk, 2020). The GTPase ERAL1 was described as a RNA chaperone to protect the 12S rRNA during mtSSU assembly as it interacts with the 3'loop of the 12S rRNA prior methylation by TFB1M (Dennerlein et al., 2010). In contrast, mtRBFA, which binds at the same site as ERAL1, supports methylation of both adenine residues in the 12S rRNA (Rozanska et al., 2017). The protease CLPP regulates the biogenesis of the mitoribosome by regulation of ERAL1 (Szczezanowska et al., 2016). Additionally, the GTPase C4orf14 (NOA1) is required as a necessary factor for mtSSU assembly (He et al., 2012). For biogenesis of the 28S

mtSSU also the endoribonuclease YBEY is obliged as it recruits uS11m into the growing particle (D'Souza et al., 2019; Summer et al., 2020).

Figure 11: Known assembly factors for 55S mitoribosome biogenesis. Picture adapted from Hanitsch and Richter-Dennerlein, 2020.

In contrast to the 12S rRNA, there are three 2'-O-ribose methylations of the 16S rRNA at position G1145 (MRM1), U1369 (MRM2) and G1370 (MRM3) (Lee and Bogenhagen, 2014; Rorbach et al., 2014). TRMT61B catalyses the methylation of A947 (Bar-Yaacov et al., 2016) and RPUSD4 is responsible for pseudouridylation of U1397 (Antonicka et al., 2017). Three factors were described to support the stability of the 16S rRNA and to be required for mtLSU assembly, namely the RNA binding proteins MTERF3 and FASTKD2, as well as the RNA helicase DDX28 (Antonicka and Shoubridge, 2015; Popow et al., 2015; Tu and Barrientos, 2015; Wredenberget al., 2013). However, their exact function still remains elusive. Within a CRISPR death screen, a regulatory model consisting of NGRN, WBSR16, RPUSD3, RPUSD4, TRUB2 and FASTKD2 was found to coordinate 16S rRNA (Arroyo et al., 2016). In addition, NGRN was reported to contain a Pfam domain, possibly required for RNA binding (Arroyo et al., 2016).

C7orf30 (MALSU1) associates exclusively with the mtLSU as it co-precipitates with proteins of the mtLSU but not of the mtSSU. Loss of MALSU1 leads to atypical assembly of 39S mtLSU and concomitantly to reduced 55S levels, suggesting a role in biogenesis of the mtLSU (Rorbach et al., 2012). In addition, MALSU1 was detected in cryo-EM structures together with LOR8F8 and mt-ACP associated with a late assembly intermediate of the mtLSU. As the complex of MALSU1, LOR8F8 and mt-ACP would sterically prevent binding of the mtSSU to the mtLSU, it was hypothesized to function as an anti-association factor during late mtLSU biogenesis (Brown et al., 2017). The *m*-AAA protease was also described to act during a late assembly step of mtLSU biogenesis, as it processes bL32m prior incorporation into the growing 39S particle (Nolden et al., 2005). Besides methylating 12S rRNA, NSUN4 shares another function with MTERF4. The

NSUN4/MTERF4 complex associates with the mtLSU and prevents subunit joining in order to control that just mature 28S and 39S are used for 55S biogenesis (Metodieiev et al., 2014).

Recently, GTPases became the centre of interest regarding mitoribosome assembly. GTPases provide energy by GTP hydrolysis which can be used to facilitate structural changes as well as to incorporate or release proteins into or from pre-existing complexes (Mai et al., 2017). GTPBP7 (MTG1) is involved during a late assembly stage of the 39S mtLSU. It promotes binding of proteins to a late assembly intermediate and interacts with uL19m and mS27, suggesting that it is involved in building the mB6 intersubunit bridge (Kim and Barrientos, 2018). GTPBP10 (OBGH2) was hypothesized to act as well as a late 39S maturation factor as it associates exclusively to the mtLSU and its loss leads to ablation of 55S mitoribosomes (Lavdovskaia et al., 2018; Maiti et al., 2018). As final mtLSU maturation step, interaction of GTPBP5 (OBGH1/MTG2) with the mtLSU was proposed in order to facilitate methylation of G1145 and U1369 and to recruit bL36m to the mtLSU (Maiti et al., 2020).

Additionally, the factors DHX30 (RNA helicase), GRSF1 (RNA-binding protein) and MPV17L2 (IMM protein) are required for proper 55S biogenesis (Antonicka and Shoubridge, 2015; Antonicka et al., 2013; Dalla Rosa et al., 2014). Nevertheless, their exact function during assembly has to be further investigated. The putative GDP/GTP exchange factor WBSCR16 (RCC1L) exists in three isoforms (Reyes et al., 2020). Isoform 1 interacts with the 28S mtSSU and isoform 3 with the mtLSU. Their targets might be GTPBP10, ERAL1 or NOA1.

2.2.2.3 Assembly of the 39S mitochondrial large subunit

A first model for the order of incorporation of mtLSU proteins into the growing particle was suggested by Bogenhagen et al., 2018 (Figure 12).

Figure 12: Scheme of 39S LSU assembly. Early binding proteins are shown in red, intermediate binding proteins in green and late binding proteins in blue. Heavy dashed lines show interaction surface areas $> 1,000 \text{ \AA}^2$, whereas lighter dashed lines indicate interaction surface areas from $1,000 \text{ \AA}^2 - 350 \text{ \AA}^2$. Early binding proteins without vast RNA contacts are visualized in bold red. Picture taken from Bogenhagen et al., 2018. Creative Commons Attribution-Non Commercial-No Derivatives License (CC BY NC ND). DOI: <https://doi.org/10.1016/j.celrep.2018.01.066>

Clusters of early binding proteins are recruited to the 16S rRNA core. One cluster contains uL3m, uL14m, bL17m, bL19m, uL22m and bL32m, which mediates the incorporation of mL39 and mL45, which have very little direct rRNA contact. The heterodimer of uL4m/uL15m together with mL49 recruit mL50, which also lacks rRNA interactions (Figure 13).

Assembly of the central protuberance was suggested within two steps. At first, mL40/mL46/mL48 were reported to bind to one side of the tRNA, followed by bL27m/uL18m/mL38/mL62 incorporation. However, the protein bL31m situated in the centre of mL40/mL46/mL48, was designated as a late binding protein. To incorporate this protein at a later stage of assembly, disassembly of the before mentioned proteins would be required.

Figure 13: Assembly of the 39S mtLSU. A) Early binding proteins are depicted in red. B) Proteins binding at an intermediate state are coloured green. C) The late binding proteins are visualized in blue. 16S rRNA and structural tRNA are shown as grey spheres. Picture taken from Bogenhagen et al., 2018. Creative Commons Attribution-Non Commercial-No Derivatives License (CC BY NC ND). DOI: <https://doi.org/10.1016/j.celrep.2018.01.066>

The intermediate/late binding proteins mL41, uL23m, uL24m, uL29m and bL34m form parts of the peptide exit tunnel. Other intermediate binding proteins contact either early binding proteins and/or the 16S rRNA as uL13m and mL66, which bind in close proximity to uL10m. The early binding proteins are mainly situated in the periphery of the mtLSU. Instead, late binding proteins are located in the interface such as uL2m, mL37 and mL65. Interestingly, uL2m is not an early binding protein despite its large contact surface to the 16S rRNA.

2.2.2.4 Assembly of the 28S mitochondrial small subunit

Similar to the mtLSU assembly, early binding proteins of the mtSSU bind to the rRNA core of the subunit. The first clusters of proteins bind to the head and lower body of the 12S rRNA (Bogehagen et al., 2018). The module in the lower body comprises bS16m and mS40, which bind to the 5' end of the 12S rRNA. mS22 interacts then with the before mentioned proteins. In addition, mS34 and mS27 are a part of this cluster, having contact with the 3' end of the 12S rRNA. Incorporation of uS5m follows, probably to mediate the contact between proteins of this cluster (Figure 14).

Figure 14: 28S mtSSU assembly. A) Early binding proteins are coloured in red whereas late binding proteins are depicted in blue. The 12S rRNA is visualized as blue spheres. B) Cartoon of mtSSU assembly. Description of dashed lines as indicated in Figure 12. Picture taken from Bogehagen et al., 2018. Creative Commons Attribution-Non Commercial-No Derivatives License (CC BY NC ND). DOI: <https://doi.org/10.1016/j.celrep.2018.01.066>

The early binding proteins in the head region bind either directly to the rRNA core (uS7m, uS9m, mS29) or to proteins incorporated priorly (mS31, mS35, mS39). A smaller subset of proteins is also binding at an early stage (bS1m, uS2m, mS23), interacting with uS9m and uS5m. uS11m, uS12m and uS17m were also designated as early binding proteins. However, they bind individually to the rRNA core but not to the other protein clusters. It has been suggested that the early binding proteins recruit the late binding proteins. Thereby, the group of uS3m, uS10m, uS14m and mS33 binds to the head group, whereas uS15m, mS25 and mS26 are recruited to the body forming contacts to the bS16m cluster. In total, early binding proteins were described to

bind on the outer surface of the mtSSU. In contrast, late binding proteins are found closer to the LSU contact site (Bogenhagen et al., 2018).

2.2.3 Disease association of 55S mitoribosome

Diseases caused by impaired mitochondrial function have an incidence of about 1 in 5000 as reviewed by Boczonadi and Horvath, 2014. In recent years, more and more patients with mutations in genes encoding for mitoribosomal proteins were identified (Table 3).

Table 3: Disease associated mitoribosomal proteins (MRPs)

MRP	mutation	clinical phenotype	OMIM	Reference
bS1m	c.356A>G, p.(Lys119Arg), deletions of exon 2 and parts of intron 1 and 2	growth retardation, craniofacial dysmorphism, developmental delay	611990	(Pulman et al., 2019)
uS2m	c.328C>T (p.Arg110Cys) c.340G>A (p.Asp114Asn) c.413G>A (p.Arg138His)	sensorineural hearing loss, hypoglycemia	611971	(Gardeitchik et al., 2018)
uS7m	c.550A>G, (p.Met184Val)	congenital sensorineural deafness, progressive hepatic and renal failure, lactic acidemia	611974	(Menezes et al., 2015)
uS14m	c.322C>T (p.Arg108Cys)	perinatal hypertrophic cardiomyopathy, neonatal lactic acidosis, growth retardation, dysmorphism, mental retardation	611978	(Jackson et al., 2019)
bS16m	c.331C>T (p.Arg111*)	agenesis of corpus callosum, mild ventricular dilatation, dysmorphism, lactic acidosis	609204	(Emdadul Haque et al., 2008; Miller et al., 2004)
mS22	c.509G>A (p.Arg170His), c.644T>C (p.Leu215Pro) c.1032_1035dup (p.Leu346Asnfs*21)	agenesis of corpus callosum, skin oedema, hypotonia, hypertrophic cardiomyopathy, lactic acidemia, hyperammonaemia, tubulopathy, atrial and ventricular septal defects, Cornelia de Lange-like phenotype	605810	(Baertling et al., 2015; Emdadul Haque et al., 2008; Saada et al., 2007; Smits et al., 2011)
mS23	c.119C>G (p.Pro40Arg)	hepatic disease	611985	(Kohda et al., 2016)
mS25	c.215C>T (p.Pro72Leu)	encephalomyopathy, dyskinetic cerebral palsy, partial agenesis of corpus callosum	611987	(Bugiardini et al., 2019)
mS34	c.321+1G>T (p.Val100_Gln107del), c.322-10G>A (p.Asn108Leufs*12, Asn108Glyfs*50) c.37G>A (p.Glu13Lys), c.94C>T (p.Gln32*)	Leigh syndrome	611994	(Lake et al., 2017)
mS39	c.415-2A>G (p.Cys139Glufs*71), c.1747-1748insCT (p.PheSerfs*3)	Leigh syndrome	614918	(Borna et al., 2019)
uL3m	c.950C>G (p.Pro317Arg), deletion	hypertrophic cardiomyopathy, psychomotor retardation	607118	(Galmiche et al., 2011)
bL12m	c.542C>T (p.Ala181Val)	growth retardation, neurological deterioration	602375	(Serre et al., 2013)
uL24m	c.272T>C (p.Leu91Pro)	cerebellar atrophy, choreoathetosis of limbs and face, mental retardation	611836	(Di Nottia et al., 2020)
mL44	c.467T>G (p.Leu156Arg), c.233G>A (p.Arg78Gln)	cardiomyopathy, liver steatosis, pigmentary retinopathy, hemiplegic migraine, Leigh-like lesions in the brain, renal insufficiency, hepatopathy	611849	(Carroll et al., 2013; Distelmaier et al., 2015)

The clinical phenotypes among all patients are quite diverse. However, what they all have in common are early-onset, fatal, multi-system disorders. For this reason, profound knowledge

about the mitoribosome and its assembly are essential to understand the pathological mechanisms leading to those diseases and to determine possible treatment options.

2.3 Scope and aims of the thesis

Aim of this doctoral thesis was to dissect the assembly of the human 39S mtLSU in further detail. Thus, a triple SILAC approach was designed to investigate the biogenesis of the mitoribosome *in vivo*. For this purpose, isolated 55S mitoribosomes were required as an internal standard for mass spectrometry measurements.

Part one of this thesis focuses on the purification of human mitoribosomes. First, the separation of mitoribosomal complexes on sucrose gradients had to be optimized. Therefore, the following questions were addressed:

- i. Which sucrose concentration has to be used within gradients to achieve the best separation of mitoribosomal particles?
- ii. Which type and concentration of salt in buffers is required to minimize unspecific protein-protein interactions but keep the ionic strength?
- iii. Which impact does the concentration of Mg^{2+} ions have on the human mitoribosome integrity?
- iv. How can the purity of the starting material be improved?

Answers to these questions were used to establish a protocol for isolation of human 55S mitoribosomes. In order to enhance the yield and quality of purified mitoribosomes, the type of detergent for mitochondrial lysis and the purification method of crude mitoribosomes were also investigated.

Within the second part of this thesis, the disease associated protein mL44 and the membrane anchor mL45 were characterized in regard of their impact within the biogenesis of the human 39S mtLSU. In order to do so, the subsequent questions have been asked:

- v. What is the role of mL44 during 39S mtLSU biogenesis?
- vi. Does loss of mL44 have an impact on mitochondrial translation and mtLSU assembly?
- vii. Does the mitoribosome require its membrane anchor to assemble?
- viii. Do mtLSU submodules assemble in absence of mL45?
- ix. Is the mtSSU assembly affected upon depletion of mL44 or mL45?

3. Materials and Methods

3.1 Materials

3.1.1 Chemicals

A list of chemicals used in this study together with their manufacturers can be found in Table 4.

Table 4: List of used chemicals in this study.

Chemical name	manufacturer
[³⁵ S]-L-methionine	Hartmann Analytic
2-Mercaptoethanol (β-Mercaptoethanol)	AppliChem GmbH
2-Propanol	Roth
Acetic acid	Roth
Acetone	Roth
Acrylamide (2xcrystallized)	Roth
Acrylamide/bisacrylamide (37.5:1) solution	Roth
Agarose NEEO ultra-quality	Roth
Ammonium acetate	Roth
Ammonium chloride (NH ₄ Cl)	MERCK
Ammonium hydroxide solution	Sigma-Aldrich
Ammonium persulfate (APS)	Roth
Ampicillin	AppliChem GmbH
Anti-FLAG M2 Affinity Gel	Sigma-Aldrich
Bacto™ Agar	BD
Bacto™ Peptone	BD
Bacto™ Tryptone	BD
Bacto™ Yeast Extract	BD
Bis-acrylamide (2X)	SERVA
Blasticidine S HCl	ThermoFisher Scientific
BPB (Bromophenol blue)	MERCK
BSA (Bovine Serum Albumin)	Sigma Life Science
Calcium chloride dihydrate	Roth
Chloramphenicol	Sigma Life Science
Chloroform	Roth
CNBr activated Sepharose 4B	GE Healthcare
cOmplete™ Protease inhibitor cocktail tablets	Roche
Coomassie Brilliant Blue R-250	Serva
Developing solution Developer G153	Agfa
Digitonin	Calbiochem
di-Potassium hydrogen phosphate	Roth

Chemical name	manufacturer
di-Sodium hydrogen phosphate dihydrate	AppliChem GmbH
DMSO (dimethyl sulfoxide)	MERCK
DNase I	Thermo Scientific
dNTP Mix	Thermo Scientific
DTT (1.4-Dithiothreitol)	Roth
EDTA (Ethylendiamine tetraacetic acid)	Roth
Emetine	Invitrogen
Ethanol	Roth
Ethidium Bromide (0.025%)	Roth
FBS (fetal bovine serum)	Biochrom
Fixing solution Rapid Fixer G354	Agfa
FLAG-peptide	Sigma-Aldrich
Formaldehyde	Sigma-Aldrich
GeneJuice® Transfection Reagent	Novagen
GeneRuler DNA Ladder Mix	Thermo Scientific
Glycerol	Sigma-Aldrich
Glycine	Roth
HEPES (4-(2-hydroxyethyl)-1-piperazineethanesulfonic acid)	Roth
Hydrochloric acid 37% w/v	Roth
Hydrogen peroxide	Sigma-Aldrich
Hygromycine B	Life Technologies
L-Glutamine 200mM (100X)	gibco
Lipofectamine RNAiMAX	Invitrogen
Magnesium chloride heptahydrate	MERCK
Manganese (II) chloride tetrahydrate	Roth
Methanol	Roth
MOPS (Morpholinopropanesulfonic acid)	Roth
NP-40 (Nonidet P40, 4-Nonylphenyl-polyethylene glycol)	Sigma Life Science
Nupage 20x running buffer	Invitrogen
NuPage LDS Sample buffer 4x	Invitrogen
Opti-MEM™	gibco
Penicillin Streptomycin	gibco
Phenol	Roth
Phosphatase alkaline	Roche
Pierce™ ECL Western Blotting Substrate	Life Technologies
Plasmocin™	invivogen
PMSF (Phenylmethyl sulphonyl fluoride)	Roth
Ponceau S (C.I. 27195)	Roth
Potassium chloride	Roth
Potassium dihydrogen phosphate	Roth
Potassium hydroxide	Roth

Chemical name	manufacturer
Precision Plus Protein™ All Blue Prestained Standards (10-250kD)	Bio-Rad
Protein-A sepharose	GE healthcare
Proteinase K	Roth
RiboLock RNase Inhibitor	Thermo Scientific
Roti-Quant® Reagent	Roth
Rubidium Chloride	Roth
SDS (sodium dodecyl sulfate)	Roth
Silver nitrate	Roth
Sodium acetate	Roth
Sodium azide	Sigma-Aldrich
Sodium carbonate	MERCK
Sodium chloride	Roth
Sodium Deoxycholate	Roth
Sodium dihydrogen phosphate	Roth
Sodium hydrogen carbonate	MERCK
Sodium hydroxide	AppliChem GmbH
Sodium pyruvate solution	Sigma Life Science
Sodium tetraborate	Sigma-Aldrich
Sodium Thiosulfate	Sigma Chemical Co.
Sucrose, D (+)	Roth
Taq DNA Polymerase	Invitrogen
TCA (Trichloroacetic acid)	Roth
TEMED (Tetramethylethylenediamine)	Roth
Trehalose	Roth
Tricine	Roth
TRIS (Tris(hydroxymethyl)aminomethane)	Roth
Tris(2-carboxyethyl)-phosphine hydrochloride (TCEP)	Sigma-Aldrich
tri-Sodium Citrate Dihydrate	Roth
Triton X-100	Roth
TRIzol™ Reagent	Ambion
Tween-20	Roth
Uridine	Sigma-Aldrich

3.1.2 Recipes of used buffers and solutions

Buffers were prepared as stated in Table 5 with Aqua dest. and autoclaved or sterile filtrated if indicated.

Table 5: Composition of used buffers and solutions in this study.

Buffer	Recipe
15 % sucrose buffer	15 % (w/v) sucrose, 100 mM NH ₄ Cl, 8mM MgCl ₂ , 20 mM Tris/HCl pH 7.5, 5 mM DTT
30 % gradient buffer	30 % (w/v) sucrose, 100 mM NH ₄ Cl, 10 mM MgCl ₂ , 20 mM Tris/HCl pH 7.4, cOmplete™ Protease inhibitor cocktail tablet 1/50 ml
30 % sucrose buffer	15 % (w/v) sucrose, 100 mM NH ₄ Cl, 8mM MgCl ₂ , 20 mM Tris/HCl pH 7.5, 5 mM DTT
5 % gradient buffer	5 % (w/v) sucrose, 100 mM NH ₄ Cl, 10 mM MgCl ₂ , 20 mM Tris/HCl pH 7.4, cOmplete™ Protease inhibitor cocktail tablet 1/50 ml
acrylamide Mix	45 % (w/v) acrylamide, 1.5 % (w/v) bis-acrylamide (32:1), sterile filtrated
anode buffer	0.2 M Tris, pH 8.9
blocking solution	5% (w/v) milk powder in TBS-T
cathode buffer	0.1 M tricine, 0.1% (w/v) SDS, 0.1M Tris, pH 8.25
cell culture cultivation medium	DMEM (Dulbecco's modified Eagle's medium), 10% (v/v) FBS, 2 mM L-glutamine, 1 mM sodium pyruvate, 50 µg/ml uridine, 100 units/ml penicillin, 100 µg/ml streptomycin, sterile filtrated
Coomassie staining solution	0.25 % (w/v) Coomassie Brilliant Blue R-250, 10 % (v/v) acetic acid, 40 % (v/v) ethanol
coupling buffer	0.1 M NaHCO ₃ pH 8.3, 0.5 M NaCl
destainer	40% ethanol (v/v), 10% acetic acid (v/v)
developing solution	6 % (w/v) Na ₂ CO ₃ , 0.0185 % (v/v) formaldehyde, 16 µM Na ₂ S ₂ O ₃
fixation solution / Stop solution	50 % (v/v) methanol, 12 % (v/v) acetic acid
FLAG-IP dilution buffer	20 mM Tris/HCl pH 7.4, 100 mM NH ₄ Cl, 10 % (v/v) glycerol, 20 mM MgCl ₂ , 1 mM PMSF, cOmplete™ Protease inhibitor cocktail tablet 1/50 ml
FLAG-IP lysis buffer	20 mM Tris/HCl pH 7.4, 100 mM NH ₄ Cl, 10 % (v/v) glycerol, 20 mM MgCl ₂ , 1 % (w/v) digitonin, 1 mM PMSF, 0.08 U/µl RiboLock RNase Inhibitor, cOmplete™ Protease inhibitor cocktail tablet 1/50 ml
FLAG-IP wash buffer with or without glycerol	20 mM Tris/HCl pH 7.4, 100 mM NH ₄ Cl, 20 mM MgCl ₂ , 1 mM PMSF, cOmplete™ Protease inhibitor cocktail tablet 1/50 ml, supplemented with or without 10 % (v/v) glycerol
freezing medium	DMEM (Dulbecco's modified Eagle's medium), 18 % (v/v) FBS, 9 % (v/v) DMSO, sterile filtrated
gel buffer	1 M Tris, 0.1 % (w/v) SDS, pH 8.45, autoclaved
high sucrose cushion buffer	60 % (w/v) sucrose, 100 mM NH ₄ Cl, 8mM MgCl ₂ , 20 mM Tris/HCl pH 7.5, 5 mM DTT
homogenisation buffer	300 mM trehalose, 10 mM KCl, 10 mM HEPES pH 7.4, 1 mM PMSF, with or without 0.2 % (w/v) BSA, autoclaved
impregnation solution	0.8 mM Na ₂ S ₂ O ₃

Buffer	Recipe
isolation dilution buffer/storage Buffer	100 mM NH ₄ Cl, 8mM MgCl ₂ , 20 mM Tris/HCl pH 7.5, 5 mM DTT
isolation lysis buffer	100 mM NH ₄ Cl, 8mM MgCl ₂ , 20 mM Tris/HCl pH 7.5, 1 % (v/v) Triton X-100, 5 mM DTT
LB medium (lysogeny broth)	1 % (w/v) tryptone, 0.5 % (w/v) NaCl, 1 % (w/v) yeast extract, autoclaved
mitoplast dilution buffer	3 % (w/v) sucrose, 100 mM NH ₄ Cl, 10 mM MgCl ₂ , 20 mM Tris/HCl pH 7.5, 0.08 U/μl RiboLock RNase Inhibitor, cOmplete™ Protease inhibitor cocktail tablet 1/50 ml
mitoplast Lysis buffer	3 % (w/v) sucrose, 100 mM NH ₄ Cl, 10 mM MgCl ₂ , 20 mM Tris/HCl pH 7.5, 1 % (w/v) digitonin, 0.08 U/μl RiboLock RNase Inhibitor, cOmplete™ Protease inhibitor cocktail tablet 1/50 ml
NP-40 lysis buffer	50 mM Tris/HCl pH 7.4, 130 mM NaCl, 2 mM MgCl ₂ , 1 % NP-40 (v/v), 1 mM PMSF, 1x PI-Mix
PBS (Phosphate buffered saline)	0.14 M NaCl, 2.7 mM KCl, 0.01 M Na ₂ HPO ₄ , 1.8 mM KH ₂ PO ₄ , pH 7.4, autoclaved
RF1 buffer	100 mM RbCl, 50 mM MnCl ₂ , 30 mM Na-acetate, 10 mM CaCl ₂ , 15% (w/v) glycerol; pH adjustment to 5.8 with Acetic acid; sterile filtrated
RF2 buffer	10 mM RbCl, 50 mM MnCl ₂ , 10 mM MOPS, 75 mM CaCl ₂ , 15% (w/v) glycerol; pH adjustment to 6.8 with NaOH; sterile filtrated
SDS sample buffer	10 % (v/v) glycerol, 2 % (w/v) SDS, 0.01 % (w/v) bromophenol blue, 63 mM Tris/HCl, pH 6.8, 5 mM DTT
silver solution	0.2 % (w/v) AgNO ₃ , 0.026 % formaldehyde
sucrose cushion buffer	34 % (w/v) sucrose, 100 mM NH ₄ Cl, 8mM MgCl ₂ , 20 mM Tris/HCl pH 7.5, 5 mM DTT
TAE buffer	40 mM Tris/acetate pH 8.0, 2 mM EDTA
TBS-T (Tris buffered saline - Tween20)	20 mM Tris/HCl (pH 7.5), 125 mM NaCl, 0.1 % (v/v) Tween20
transfer buffer	20 mM Tris, 0.02 % (w/v) SDS, 150 mM glycine, 20 % (v/v) ethanol

3.1.3 Disposables and kits

All disposables and kits used in this study are listed in Table 6.

Table 6: Used disposables and kits.

Item	Manufacturer
Amicon® Ultra-0.5 Centrifugal Filter Devices 100K	Merck Millipore
Amicon® Ultra-15 Centrifugal Filter Devices 100K	Merck Millipore
Amicon® Ultra-4 Centrifugal Filter Devices 100K	Merck Millipore
Blotting paper	Heinemann Labortechnik
Bottle Top Filter 500 ml, 45 mm neck	Corning
Cell culture flask Nunc™ EasYFlask™ Nunclon™ Delta Surface 25cm ² , 75cm ²	Thermo Scientific
Cellstar® Cell Culture Dishes, PS, 145/20 mm	Greiner Bio-One
Cellstar® Cell Culture Plate 6, 12, 24, 96 Well	Greiner Bio-One
Cellstar® Tubes 50 ml, 15 ml	Greiner Bio-One
Centrifuge bottles polypropylene with caps (29 x 104 mm), 50 ml	Beckman Coulter
CryoPure Tube 1.6 ml	Sartstedt
Disposable hypodermic needle Sterican® 21G x 3 1/8" / Ø 0.80 x 80 mm, 14G x 3 1/8" / Ø 2.10 x 80 mm	B. Braun
Econo-Pac® Disposable Chromatography Columns, 10 ml	Bio-Rad
Fast digestion enzymes	Thermo Fisher
First Strand cDNA Synthesis Kit	Thermo Scientific
Graduated filter tips 1000 µl, 300 µl, 20 µl, 10 µl	Greiner Bio-One
Immobilon®-P membrane, PVDF, 0.45 µm	Merck Millipore
KOD Hot Start DNA Polymerase	Novagen
MColorpHast™ pH indicator stripes pH 5.0-10.0	Merck Millipore
Micro tube 1.5 ml protein Low binding	Sarstedt
Micro tubes 2.0 ml, 1.5 ml	Sarstedt
Multiply®- Pro cup 0.2 ml	Sarstedt
Nitrocellulose membrane Amersham™ Protran™ 0.2µm NC	GE Healthcare Life Science
NuPAGE™ 4-12% Bis-Tris Midi Gel	Invitrogen
Open-top centrifuge tubes polyallomer (13x51 mm)	Seton
Open-top centrifuge tubes polyallomer (25x89 mm)	Seton
Open-top polyclear™ centrifuge tubes (14x89 mm)	Seton
Pipette tips 1000 µl, 200 µl, 10 µl	Sarstedt
QuickExtract™ DNA Extraction Solution	Lucigen
Rapid DNA Ligation Kit	Thermo Scientific
Reaction tubes 0.6 ml	Biozym
SafeSeal tube 5 ml	Sarstedt
SensiMix™ SYBR Low-ROX Kit	Bioline
Spin columns Mobicol "classic"	MoBiTec
Super RX-N Fuji Medical X-ray film	Fujifilm
Syringe Omnifix® Luer Lock Solo 50ml, 10 ml	B. Braun
TOPO TA Cloning® Kit for Sequencing	Invitrogen
Wizard® Plus SV Minipreps DNA Purification System	Promega

3.1.6 Antibodies

Primary antibodies were purchased from ProteinTech Europe (Manchester, United Kingdom), Merck KGaA (Darmstadt, Germany), Bio-Techne GmbH (Wiesbaden, Germany), Santa Cruz Biotechnology, Inc. (Heidelberg, Germany) or abcam (Cambridge, United Kingdom). Home-made antibodies were obtained by injecting purified proteins or synthetic peptides into rabbits and subsequent serum retrieval. A complete list of primary antibodies used in this doctoral work is shown in Table 10. Secondary antibodies coupled with HRP (goat-anti-rabbit and goat-anti-mouse) were purchased from Dianova GmbH (Hamburg, Germany).

Table 10: List of primary antibodies used in this study.

Protein	Antibody	Company
uL1m	Anti-MRPL1 rabbit polyclonal	home-made
uL3m	Anti-MRPL3 rabbit polyclonal	ProteinTech (16584-1-AP)
uL10m	Anti-MRPL10 rabbit polyclonal	ProteinTech (16652-1-AP)
bL12m	Anti-MRPL12 rabbit polyclonal	ProteinTech (14795-1-AP)
uL13m	Anti-MRPL13 rabbit polyclonal	ProteinTech (16241-1-AP)
bL20m	Anti-MRPL20 rabbit polyclonal	ProteinTech (16969-1-AP)
bL21m	Anti-MRPL21 rabbit polyclonal	ProteinTech (16978-1-AP)
uL23m	Anti-MRPL23 rabbit polyclonal	home-made
uL24m	Anti-MRPL24 rabbit polyclonal	ProteinTech (16224-1-AP)
bL32m	Anti-MRPL32 rabbit polyclonal	home-made
mL39	Anti-MRPL39 rabbit polyclonal	home-made

3.2 Methods

3.2.1 Molecular biology techniques

3.2.1.1 Polymerase chain reaction (PCR)

For amplification of DNA fragments via PCR the KOD Hot Start DNA Polymerase (Novagen®) was used according to the manufacturer's instructions. Primers were designed in respect to which DNA area had to be amplified and the melting temperature adjusted. To set up the reaction, 25 mM MgSO₄, 2 mM dNTPs, 10 µM forward primer, 10 µM reverse primer, template DNA, 1 µl polymerase (1 U/µl) and 5 µl 10x reaction buffer (part of the KOD Hot Start DNA Polymerase Kit) were mixed and the total reaction volume was adjusted with Aqua dest. to 50 µl. Depending on the purpose either 10 ng plasmid DNA or 2 µl of a reverse transcription reaction was used as template. The reaction mixture was placed into the Thermal Cycler (GeneTouch) and the PCR was started by activation of the polymerase at 95°C for 2 min, followed by a denaturing step at 95°C for 20 s. The annealing temperature was calculated depending on the used primers and applied for 10 s. Length of extension at 70°C was chosen corresponding to the size of the DNA fragment to be amplified. Denaturation, annealing and extension were repeated in cycles for 20 to 40 times. The obtained PCR product was analysed via agarose gel electrophoresis.

3.2.1.2 Agarose gel electrophoresis

To analyse or purify DNA, agarose gel electrophoresis was used. To cast a gel, agarose (Roth) was dissolved in TAE-buffer by heating, to obtain a 1 % (w/v) or 1.5 % (w/v) solution depending on the size of the DNA fragment to be purified. The melted agarose was cooled down to approximately 50°C before adding ethidium bromide (Roth) up to a concentration of 1 µg/ml. Samples were mixed with either 50 % glycerol (v/v) or 10 % Fast Digest Green Buffer (Thermo Scientific), loaded onto the gel next to the molecular weight marker (GeneRuler DNA Ladder Mix) and were run for 10 min at 120 V. To finally visualize the DNA fragments, they were exposed to UV-light.

3.2.1.3 Purification of PCR products

PCR products were either directly purified by using the Wizard® SV Gel and PCR Clean-Up System (Promega) or first loaded onto an agarose gel, the respective DNA band excised and then purified as recommended by the company.

3.2.1.4 Determination of DNA/RNA concentrations

To measure the DNA or RNA concentration within a solution, 1 µl of the samples was analysed by determining the absorption at 260 nm with the Nanodrop™ One^C Microvolume UV-Vis Spectrophotometer (Thermo Scientific).

3.2.1.5 Molecular cloning

For molecular cloning, the plasmid DNA and the PCR product, which should be inserted into the plasmid, were subjected to restriction digestion with Fast digestion enzymes (Thermo Fisher). Conditions for digestion were chosen according to the manufacturer's instructions. Two Micrograms of insert and 4 µg of vector DNA were digested for 30 min at 37°C, each in 40 µl total reaction volume (DNA, 2 µl restriction enzyme A, 2 µl restriction enzyme B, 4 µl 10x Fast Digest Buffer, adjusted to the final volume with Aqua dest.). To avoid re-ligation, the vector was dephosphorylated by adding 2 µl alkaline phosphatase (Roche) and 4 µl 10x buffer (supplied from alkaline phosphatase kit) and incubated for 45 min at 37°C. Vector and insert DNA were purified as described before and ligation was set up usually in a 1:6 (vector : insert) molar ratio using the Rapid DNA Ligation Kit (Thermo Scientific). To carry out the reaction 50 ng vector and an appropriate amount of insert were mixed with 5x ligation buffer, 1 µl T4 DNA-Ligase, adjusted to a total reaction volume of 20 µl with Aqua dest. and incubated for 30 min at 22°C. Four microliter from this reaction were used to transform 100 µl chemically competent *E. coli* (XL1-blue). Single clones were picked on the next day, inoculated in LB-media containing 100 µg/ml ampicillin and incubated for 37°C over night shaking. Plasmid DNA was isolated by using Wizard[®] Plus SV Minipreps DNA Purification System (Promega). To analyse, whether the isolated plasmids contained the desired insert, a test digestion was performed with approximately 150 ng of plasmid DNA followed by an agarose gel electrophoresis of the samples. Positive clones were chosen and sent for sequencing (Microsynth SEQLAB Göttingen).

3.2.1.6 Transformation of chemically competent *E. coli*

In order to bring plasmid DNA into bacteria, transformation via heat shock was performed. For this reason, 4 µl DNA was added to 100 µl of chemically competent *E. coli* (XL1-blue) cells, incubated for 30 min on ice followed by a heat shock at 42°C for 1 min. Cells were rested on ice for 2 min prior adding of 900 µl of pre-warmed LB-media and subsequent incubation at 37°C for 1 h shaking. The bacterial suspension was centrifuged at 8,000xg for 1 min at room temperature, the bacterial pelleted was resuspended in 100 µl LB-media and finally plated onto LB-agar-plates (15 g/l agar) containing ampicillin (final concentration: 100 µg/ml) as selective antibiotic.

3.2.1.7 RNA isolation from cultured cells

RNA isolation from cultured cells was performed as described previously by (Chomczynski and Sacchi, 2006). HEK293T cells were seeded into a 6-well cell culture plate and harvested upon 80 % confluency with PBS supplemented with 1 mM EDTA. Cells were centrifuged at 1,000xg for 5 min at room temperature. The cell pellet was carefully resuspended with 500 µl TRIzol™ Reagent (Ambion) and incubated for 5 min at room temperature. Next, 100 µl chloroform were added and the sample was shaken by hand for 15 s followed by an incubation for 3 min at room temperature. Subsequently, the sample was centrifuged at 12,000xg for 15 min at 4°C to separate the RNA from DNA and proteins. The upper aqueous phase containing the RNA was transferred into a new reaction tube and 250 µl isopropanol were added and incubated for 10 min at room temperature to precipitate the RNA. The RNA was pelleted by centrifugation at 12,000xg for 10 min at 4°C, washed once with 80 % (v/v) ethanol and dried by several short centrifugation steps followed by removal of the supernatant. Finally, 10 µl Aqua dest. supplemented with 0.5 µl RiboLock RNase Inhibitor (Thermo Scientific) were added to the RNA pellet and incubated over night at 4°C for complete dissolving. The concentration of the RNA was determined as described before. For long-term storage, the RNA was kept at -80°C.

3.2.1.8 cDNA preparation

Complementary DNA was prepared from RNA via reverse transcription by using the First strand cDNA synthesis kit (Thermo Scientific) according to the specifications of the manufacturer. All steps were carried out in a thermal cycler. To set up the reaction, 1 µg of mRNA was used, 1 µl of 100 µM oligo (dT)₁₈ were added and the total volume was adjusted to 11 µl with Aqua dest.. The mixture was incubated at 65°C for 5 min and afterwards cooled down on ice for 2 min. Upon addition of 4 µl 5x reaction buffer, 1 µl RiboLock RNase Inhibitor (20 U/µl), 2 µl 10 mM dNTP Mix and 2 µl M-MuLV Reverse Transcriptase, the reaction was incubated at 37°C for 60 min and next at 70°C for 5 min. The obtained cDNA was either used directly for PCR or stored at -20°C.

3.2.1.9 Isolation of genomic DNA from cultured cells

For isolation of genomic DNA from cultured HEK293T cells the QuickExtract™ DNA Extraction Solution (Lucigen) was used according to the manufacturer's instructions. For this purpose, cells were seeded into a 96-well cell culture plate and cultured until they reached confluency. Cells were harvested and mixed with 50 µl QuickExtract Solution, vortexed for 15 s followed by an incubation at 65°C for 10 min. After another 15-s vortex step the sample was incubated at 98°C for 5 min and diluted with 100 µl Aqua dest. The extracted genomic DNA was stored until usage at -20°C. To sequence specific areas of the gDNA a PCR with respective primers was carried out.

The PCR product was purified and sent in for sequencing (Microsynth SEQLAB Göttingen). Analysis of the obtained sequences was performed by using the Genious® Software.

3.2.1.10 TOPO® sequencing

For sequencing of heterozygous HEK293T^{-/-} cell lines TOPO® sequencing was applied. The linearized plasmid pCR™4-TOPO® included in the TOPO TA Cloning® Kit for Sequencing (Invitrogen) has a covalently bound Topoisomerase I and 3' thymidine overhangs. The sequence which should be analysed, was amplified via PCR by using *Taq* polymerase according to the manufacturer's instructions to obtain a deoxyadenosine at the 3' end. To set up the TOPO® cloning reaction, 4 µl of the respective PCR product were mixed with 1 µl of TOPO® vector and 1 µl salt solution followed by an incubation for 5 minutes at room temperature. Afterwards the sample was cooled down on ice to stop the reaction. Transformation was performed by adding 2 µl of the reaction into a vial of One Shot® chemically competent *E. coli* (TOP10). Bacterial cells were incubated on ice for 10 min, the heat-shock was performed for 30 s at 42°C and the cells were again placed on ice. Next, 250 µl of pre-warmed S.O.C. medium was added and cells were shaken at 200 rpm at 37°C for 1 h. Finally, 50 µl of cells were plated on a prewarmed LB-plate containing 100 µg/ml ampicillin and incubated at 37°C overnight. Twenty single colonies were picked and further processed as described in 3.2.1.5. Each colony contained just one variant of the sequence of the heterozygous HEK293T^{-/-} cell line and the sequencing results were analysed by using the Genious® Software.

3.2.2 Cell culture techniques

3.2.2.1 Cell culture maintenance

Human embryonic kidney cell lines (Flp-In™ T-REx™ 293: WT / mL44^{-/-} / mL44 Rescue / mL45^{-/-} / mL45Rescue) were maintained in cell culture cultivation medium (see Table 5) at 37°C in a humidified atmosphere enriched with 5% CO₂. When confluent, cells were passaged. For this purpose, cells were harvested with PBS supplemented with 1 mM EDTA and centrifuged at 1000xg for 5 min at room temperature. The cell pellet was resuspended with cell culture cultivation medium and an appropriate number of cells was seeded into a 75cm² cell culture flask for further cultivation or into cell culture dishes for expansion. The same procedure was applied to harvest cells for further experiments. For long-term storage of cells in liquid nitrogen, obtained cell pellets were resuspended in freezing medium (compare Table 5). Cells were tested on a regular basis upon Mycoplasma contamination. If a contamination was detected cells were treated with plasmocin (Invivogen) for 2 weeks and tested again.

3.2.2.2 Generation of stable inducible expression cell lines

The HEK293T knock-out cell lines mL44^{-/-} and mL45^{-/-} generated via CRISPR/Cas9 technology were kindly provided by Dr. Ricarda Richter-Dennerlein. Both knock-out cell lines were made in a WT background carrying the Flp-In™ T-REx™ cassette. To rescue the respective phenotypes both cell lines were transfected with plasmids carrying the genetic information of the FLAG-tagged copy of the protein to generate stable inducible expression cell lines as described by (Mick et al., 2012; Richter-Dennerlein et al., 2016). Three days prior to transfection knock-out cells were seeded into a 6-well cell culture plate to reach a cell confluency of approximately 50 % on the day of transfection. For transfection, serum free media (Opti-MEM™ - gibco) was mixed with the transfection reagent (GeneJuice® - Novagen) according to the manufacturer's instructions and incubated for 5 min at room temperature. Afterwards 0.9 µg pOG44 and 0.1 µg pcDNA5/FRT/TO containing the respective construct was added to the transfection mix and another 15-min incubated at room temperature. This mixture was added to the cells which were maintained in cell culture cultivation medium without penicillin and streptomycin. Selection of positive clones having the desired insert started two days after transfection with 100 µg/ml hygromycin B and 5 µg/ml blasticidin S. Approximately four weeks after start of the selection single clones could be isolated. After induction with tetracycline for 24 h analysis of expression could be carried out via western blot.

3.2.2.3 Tetracycline titration

To test which concentration of tetracycline was required to get an expression level of the FLAG-tagged version of the protein similar to the endogenous one, a tetracycline titration was performed. For this purpose, cells were seeded into a 6-well cell culture plate and different concentrations of tetracycline (250 ng/ml, 100 ng/ml, 10 ng/ml, 1 ng/ml, 0.1 ng/ml, 0 ng/ml) were applied in cell culture cultivation medium. After 24 h cells were harvested and tested for expression by Western Blot.

3.2.2.4 [³⁵S] *de novo* synthesis of mitochondrial encoded proteins

To assess the *de novo* synthesis of mitochondrial encoded proteins a [³⁵S]Methionine labelling was carried out according to protocols by (Chomyn, 1996; Lavdovskaia et al., 2018). Therefore, cells were seeded into 25 cm² cell culture flasks. On the day of the experiment, the cell culture cultivation medium was removed from the cells and replaced by DMEM without methionine, cysteine and FCS. Cell were incubated for 10 min at 37°C. This washout step was done twice to remove unlabelled methionine. To inhibit cytosolic translation, cells were treated for 10 min at 37°C with media containing 100 µg/ml emetine and 10 % (v/v) FCS. Afterwards, cells were

incubated at 37°C with 200 µCi/ml [³⁵S]Methionine for 1 h and then harvested. The obtained cell pellet was washed four times with PBS and cells were lysed. Proteins were separated via SDS-PAGE and signals from radiolabelled proteins were visualized using the Typhoon FLA 9500 Phosphoimager (GE Healthcare).

3.2.3 Isolation of mitochondria

Isolation of crude mitochondria was carried out as described previously by (Callegari et al., 2016). In brief, HEK293T cells were harvested with PBS supplemented with 1 mM EDTA and pelleted at 1,000xg for 5 min at room temperature. The cellular pellet was solubilized in homogenization buffer with 0.2 % (w/v) BSA and incubated for 5 min on ice. To disrupt the cell membrane the cells were homogenized 20 times with a motor-driven potter at 800 rpm. The homogenate was subjected to several differential centrifugation steps in a tabletop centrifuge. At first, the homogenate was centrifuged at 400xg for 10 min at 4°C to remove the cellular debris. The supernatant was collected and the cellular pellet homogenized once or twice again. To pellet the mitochondria all obtained supernatants were combined and spun at 11000xg for 10 min at 4°C. The crude mitochondria were washed once in homogenization buffer without BSA and PMSF and subjected to another clarifying spin. Afterwards, the mitochondria were solubilized again and centrifuged at 400xg for 2 min at 4°C to remove eventual contaminations with cellular debris. The obtained supernatant contained the crude mitochondria which could be used for further processing or analyses.

For large scale isolation of mitochondria, the centrifugation steps were adapted due to the larger sample volumes: The slow spin was carried out at 1,000xg for 10 min at 4°C and the fast spin was performed at 20,000xg for 30 min at 4°C in a SS34 Rotor in a Sorvall RC 6 Plus centrifuge. All other conditions remained the same.

3.2.4 Mitochondrial or mitoplast lysate preparation

For lysis of mitochondria or mitoplasts the organelles were dissolved in mitoplast lysis buffer (mitochondrial concentration: 2 mg/ml, detergent/protein ratio 5:1) and incubated for 20 min on ice with occasional vortexing. To pellet the non-soluble parts, the solution was centrifuged for 15 min at 16,000xg at 4°C and the supernatant was transferred into a new reaction tube and was further processed by sucrose gradient centrifugation.

3.2.5 Protein co-immunoprecipitation

For investigation of protein-protein interactions, protein co-immunoprecipitation was performed according to (Dennerlein et al., 2015) with some modifications. Specific HEK293T cell lines expressing FLAG-tagged variants of proteins were induced for 24 h with corresponding concentrations of tetracycline and mitochondria were isolated from these cell lines as described before. Mitochondria were resuspended in FLAG-IP lysis buffer (detergent to protein ratio 5:1) and incubated for 30 min on ice with concomitant vortexing. The lysate was centrifuged for 10 min at 16,000xg at 4°C and the supernatant was transferred to a precooled low binding tube and diluted 1:1 with FLAG-IP dilution buffer. Anti-FLAG M2 affinity gel beads (1 mg protein/30 µl gel suspension containing 50 % beads) were washed three times with FLAG-IP wash buffer with glycerol, prior to loading of the sample onto the beads and subsequent binding of the FLAG-tagged protein and its interaction partners on a rotating wheel at 4°C for 1 h. To remove the unbound and not interacting proteins of the target protein, the beads were washed for 10 times with FLAG-IP Wash buffer with glycerol by centrifugation at 5,000xg for 30 s at 4°C and subsequent buffer exchange. If the co-immunoprecipitated complexes together with the FLAG-tagged protein were further separated via sucrose gradient centrifugation, the beads were washed 7 times with FLAG-IP wash buffer with glycerol and 3 times with FLAG-IP wash buffer without glycerol to avoid sinking of the sample into the gradient. After washing of the beads, the target protein and the co-immunoprecipitated complexes were eluted within a 30-min incubation step at 4°C at 1,000 rpm shaking in the presence of FLAG peptide (20 µg of FLAG peptide/1 mg of initial mitochondria) diluted 1:20 in FLAG-IP wash buffer with or without glycerol. The eluate containing the FLAG-tagged protein and its interaction partners was either subjected to sucrose gradient centrifugation or directly analysed via SDS-PAGE followed by western blotting.

3.2.6 Sucrose gradient centrifugation

To separate mitoribosomal complexes from each other, sucrose gradient centrifugation was performed as described by Lavdovskaia et al., 2018, with some changes. Therefore, 5-30 % linear sucrose gradients were casted. The top half-fill position of the centrifugation tube (14x89 mm, SETON) was marked by using the SW41 marker block. Half of the tube was filled with 5 % gradient buffer. By using a syringe and a needle the 30 % gradient buffer was carefully layered below the low percentage sucrose solution until the tube was completely filled. The tubes were closed with short rubber caps used for isokinetic sucrose gradient centrifugation. Linear sucrose gradients were prepared by using the program "Rotor: SW41, caps: short, 5-30% sucrose 1 step gradient" of the Gradient Station™ (BioComp) according to the manufacturer's instructions. Prior to usage,

prepared gradients were left for stabilization for 1 h at 4°C. For separation of mitoribosomal complexes either 300 µl of immunoprecipitation eluate or 300 µl of lysed mitochondria or mitoplasts were loaded on top of a 5-30 % gradient. If the sample volume was less than 300 µl, the volume was filled up with either FLAG-IP dilution buffer or mitoplast dilution buffer. The loaded sample volume was withdrawn from the gradient before. Gradients were centrifuged for 15 h at 79,000xg at 4 °C (Ultracentrifuge: Optima L-90K, Rotor: SW41Ti, Beckman Coulter). After the centrifugation, the gradients were fractionated by using the Gradient Station™ (BioComp) with the following settings: speed 0.3, distance 5.15 mm, fractions 16. These settings were leading to a fraction volume of approximately 730 µl. Fractions were precipitated and analysed via SDS-PAGE followed by western blotting.

3.2.7 Protein analysis

3.2.7.1 Protein precipitation

To concentrate proteins within fractions after sucrose gradient centrifugation, proteins were precipitated with ethanol. Therefore, to each fraction the 2.5-fold 100 % ethanol (ice cold) and the 1/3-fold 3 M sodium acetate pH 6.5 of the sample volume were added. Samples were frozen at -20°C for at least 2 h. Afterwards, proteins were pelleted for 15 min at 20,817xg at 4 °C and subsequently washed once with 80 % (v/v) ethanol before being dissolved in SDS sample buffer containing 50 mM DTT.

3.2.7.2 Cell lysate preparation

Harvested HEK293T cells were solubilized with an appropriate volume of NP40 lysis buffer and vortexed for 30 s at room temperature. After a clarifying spin at 600xg for 2 min at 4°C the supernatant was transferred into a new reaction tube and the protein concentration was determined. Samples can be stored at -20°C (in SDS sample buffer) or for long term storage at -80°C.

3.2.7.3 Bradford assay

Protein quantification was performed as described by (Bradford, 1976). Therefore, samples were mixed with Roti-Quant® reagent (Roth) and the absorbance was measured with a micro plate reader at 595 nm. With the help of a standard curve of different dilutions of 0.1 % (w/v) BSA the protein concentration of the sample was calculated.

3.2.7.4 SDS-PAGE

In order to separate proteins according to their size samples were subjected to SDS-PAGE. Due to the size of mitoribosomal proteins Tricine-SDS-PAGE was chosen as best option for protein separation according to (Schägger, 2006). Gel pouring stations and running chambers were custom made by the mechanical service department. For best resolution, either 10 – 18 % or 8 – 14 % gradient acrylamide gels were casted as dissolving gel overlaid by a 4 % stacking gel. SDS sample buffer was added to the samples. Prior to the electrophoresis, samples were incubated for 15 min at 37°C shaking. As a marker, the Precision Plus Protein™ All Blue Prestained Standard (Bio-Rad) was used. Gel electrophoresis was performed in cathode and anode buffer for 16 h overnight at 80 V and 25 mA. After electrophoresis, the proteins were visualized via gel staining or western blotting followed by immunostaining.

3.2.7.5 Silver staining

Silver staining is an easy possibility to stain proteins in the nanogram range. The staining procedure was performed as described by (Chevallet et al., 2006) with some changes. All steps were performed at room temperature on a rocking table. The gel was fixed in fixation solution for at least 1 h. Afterwards the gel was washed twice with 50 % (v/v) ethanol and once with 30 % (v/v) ethanol for 20 min respectively. This step was performed to remove the acetic acid which would lead to a decomposition of sodium thiosulphate present in the impregnation solution and subsequently to silver sulphite formation. The ethanol washing steps were followed by gel impregnation with impregnation solution for exactly 60 s. Next, the gel was washed three times with Aqua dest. for each 20 s to remove the sodium thiosulphate from the gel surface. The gel was then impregnated for 20 min with silver solution and subsequently washed three times for 20 s with Aqua dest.. To visualize the proteins, the gel was treated with developing solution for approximately 5 min until the bands were clearly visible. This was followed by two further washing steps for 2 min with Aqua dest. and finally, the developing was stopped by placing the gel into stop solution. The stained gel was stored in 5 % (v/v) acetic acid solution.

3.2.7.6 Western blot

For further analyses, proteins were required to be transferred from polyacrylamide gel to nitrocellulose membrane (GE Healthcare Life Science) or PVDF membrane (Merck Millipore) by semi-dry blotting. For this purpose, the membranes were either activated with methanol (PVDF) or Aqua dest. (nitrocellulose). Before blotting, membranes, blotting paper (Heinemann Labortechnik) and the gel were equilibrated in transfer buffer. All components were assembled

into the blotting chamber and transfer of the proteins from gel onto membrane occurred within 2 h at 250 mA and 25 V.

3.2.7.7 Membrane staining

After blotting, the membranes were stained to visualize all immobilized proteins. In brief, nitrocellulose membranes were stained with Ponceau S for 5 min at room temperature on a rocking table. To remove unbound Ponceau S, the membranes were washed shortly several times with Aqua dest. before drying.

For staining of PVDF membranes, Coomassie Brilliant Blue R-250 (Serva) was used. Prior to staining, the membrane was activated with methanol, then stained with Coomassie staining solution for approximately 5 min, followed by several washing steps with destainer and then dried.

3.2.7.8 Immunostaining

Dried membranes were activated either with Aqua dest. (nitrocellulose) or methanol (PVDF) followed by a washing step with TBS-T. Membranes were incubated for at least one hour at room temperature with blocking solution to avoid unspecific binding of antibodies. The membranes were incubated overnight with primary antibodies, which are prepared in blocking solution plus 0.2 % sodium azide. On the next day, the membranes were washed three times for 10 min with TBS-T on a rocking table to remove unbound antibodies. Membranes were then incubated with secondary antibodies coupled with HRP for 1.5 h. Subsequent detection of the antibody-protein complexes was performed after three additional washing steps with TBS-T, (each for 10 min) by using the Pierce™ ECL Western Blotting Substrate (Life Technologies) according to the manufacturer's instructions. The chemiluminescence signals were visualized by using X-ray films (Agfa). For quantification, X-ray films were scanned and signals were quantified by using the software ImageQuant TL (GE Healthcare). This procedure was required, as some antibodies against mitoribosomal proteins were not possible to detect by using fluorescence protein coupled secondary antibodies, due to their low abundance.

3.2.8 Antibody purification

To purify an antibody, the protein against which the antibody was generated needed to be coupled to CNBr activated sepharose. For this reason, CNBr activated sepharose was soaked on a glass funnel filter with sintered glass disc for 15 min in 1 mM HCl, followed by a washing step with 1 mM HCl. The pH of the beads was adjusted to 8 by rinsing with coupling buffer. Beads were transferred into a 50-ml tube, mixed with the protein dissolved in coupling buffer and incubated in an end over end shaker for 2 h at room temperature. Afterwards, beads were washed first with coupling buffer and second with 0.1 M Tris/HCl pH 8, prior to an overnight blocking step with 0.1 M Tris/HCl pH 8 at 4°C. On the next day, beads were transferred into a column and washed for three times with 0.1M sodium acetate / 0.5M NaCl pH 5 and another three times with 0.1 M Tris/HCl / 0.5 M NaCl pH 8. For purification of the respective antibody, beads were washed with TBS. Next, the antibody serum was diluted 1:1 with TBS and passed over the column containing the beads coupled with the corresponding protein to bind for two times. This was followed by another washing step with TBS before elution was performed via pH shift by using 100 mM glycine/HCl pH 2.5. A total of six fractions containing the purified antibody were collected and mixed with 0.1 M Tris pH 8. The beads were regenerated with 10 mM Tris pH 7.5 until the pH reached 7.5, which was tested by using pH indicator stripes. Finally, the beads were washed with TBS complemented with 0.02 % sodium azide before they were stored at 4°C.

3.2.9 Preparation of competent cells

Preparation of transformation competent *E. coli* with divalent cations was performed as described previously by (Hanahan, 1983) with some changes. XL1-blue cells were inoculated as a pre-culture in LB medium overnight at 37°C and continuous shaking. On the following day, the pre-culture was diluted 1:100 with LB medium and grown at 37°C while shaking to mid-log phase ($OD_{600}=0.2-0.3$). Cells were incubated on ice for 15 min, pelleted at 900xg for 10 min at 4°C and subsequently resuspended in sterile RF1 buffer and further incubated on ice for 30 min. After this, bacteria were again pelleted at 900xg for 10 min at 4°C and the obtained pellet was resuspended in cold RF2 buffer, followed by a 15-min incubation step on ice. The competent cells were aliquoted, snap frozen in liquid nitrogen and stored at -80°C.

4. Results

4.1 Purification of mammalian mitoribosomes

4.1.1 Introduction

Within this doctoral thesis the assembly of the 39S mtLSU should be further investigated. Therefore, a triple SILAC approach (Figure 15) was set up in collaboration with Prof. Dr. Henning Urlaub to analyse the biogenesis of the mitoribosome similar as already described by Chen and Williamson (2013) for the assembly of the bacterial ribosome.

Figure 15: Triple SILAC approach. HEK293T WT cells were grown for at least 10 days in heavy SILAC medium (Arg⁺¹⁰, Lys⁺⁸) and then shifted into medium SILAC medium (Arg⁺⁶, Lys⁺⁴). Cells were harvested at different points of time; mitochondria isolated and mitoribosomal complexes separated by sucrose gradient ultracentrifugation. Gradients were fractionated and an internal standard of lightly labelled purified mitoribosomes (Arg⁺⁰, Lys⁺⁰) was added into each fraction. Fractions were subjected to MS analysis.

After separation of mitoribosomal particles on sucrose density gradients, the behaviour of every mitoribosomal protein (MRP) in each fraction of the gradient will be investigated by quantitative mass spectrometry. This approach will reveal the order and time point of incorporation of individual MRPs, their ability to form submodules and to finally create a map for the assembly of the mitoribosome. Even if an assembly map for the mammalian 55S mitoribosome was suggested recently (Bogenhagen et al., 2018), the biogenesis of the mitochondrial ribosome is not solved in

detail. Data used in the aforementioned publication were gained by SILAC analysis of the complete 55S mitoribosome. In contrast, the planned triple SILAC approach aims to determine each MRP and assembly factor in each fraction along the gradient in a quantitative way at different time points. For this, purified mitoribosomes lightly labelled (Arg^{+0} , Lys^{+0}) were used as an internal standard, which were spiked into each fraction at each time point. To obtain the required human 55S mitoribosomes, different parameters of the separation of mitoribosomal complexes on sucrose gradients had to be optimized in order to establish a method for mitoribosome purification. Additionally, purified mitoribosomes were not only required for this specific SILAC study but also for functional assays and structural analyses in the future to address the mammalian mitoribosome assembly. Some protocols for mitoribosome isolations were already published but did not fit to our requirements. (Aibara et al., 2018; Carroll, 2017; O'Brien and Kalf, 1967; Spremulli, 2007). Hence, a new protocol to purify 55S mitoribosomes from human cells had to be determined.

4.1.2 Optimization of separation of mitoribosomal complexes on sucrose gradients

To analyse assembly intermediates and to purify mitoribosomes, the separation of mitoribosomal complexes on sucrose gradients had to be improved in regard of sucrose concentration, buffer conditions and purity of starting material.

4.1.2.1 Sucrose concentration

First of all, the impact of different sucrose concentrations on mitoribosome separation on sucrose gradients was tested. Therefore, mitochondria were isolated from HEK293T WT cells and lysed as described in chapter 3.2.3 and 3.2.4. The cleared lysate was loaded either on top of a 5-30 % sucrose gradient or on top of a 10-30 % gradient and sucrose gradient ultracentrifugation was performed according to 3.2.6. Gradients were fractionated, fractions were ethanol precipitated and further analysed by SDS-PAGE and western blot with specific antibodies for mtLSU or mtSSU. In a 5-30 % gradient the 55S ribosome migrates in fraction 12/13, the 39S mtLSU in fraction 10 and the 28S mtSSU in fraction 7/8. In contrast, in a 10-30 % gradient the 55S particle is in fraction 9/10, the 39S in fraction 7 and the 28S in fraction 5/6. Ribosomal complexes including assembly intermediates are better separated in the lower dense fractions using a 5-30% sucrose gradient instead of a 10-30 % gradient (Figure 16). For this reason, a 5-30 % sucrose gradient was used for further investigations.

Figure 16: Impact of sucrose concentration on complex separation. Mitochondrial lysate (0.5 mg) was subjected to sucrose gradient ultracentrifugation. Collected fractions (1-16) were precipitated and analysed by SDS-PAGE and western blot using specific antibodies for mtLSU (mL62) and mtSSU (uS15m, bS16m). Input = 50 µg lysed mitochondria. A) 5-30% sucrose gradient. B) 10-30% sucrose gradient.

4.1.2.2 Type and concentration of salt

As a next step, the type of salt used in buffers for sucrose gradients was analysed. Sodium chloride needs to be avoided as it dissociates bacterial 70S ribosomes (Hardy and Turnock, 1971). Usually, potassium chloride is used as salt in buffers for separation of mitoribosomal complexes in order to reduce unspecific protein-protein-interactions and to keep the ionic strength (Carroll, 2017). However, studying the assembly and function of bacterial ribosomes ammonium chloride is commonly used. In the following, both salts were compared in their attribute on complex separation and 55S maintenance. As described before, mitochondrial lysates were subjected to sucrose gradient ultracentrifugation in buffers containing either 100 mM KCl or 100 mM NH₄Cl. Under both conditions, the 55S ribosome was preserved, however, a better separation of 39S from 55S was observed in the presence of NH₄Cl (Figure 17). Hence, in the following experiments NH₄Cl was the salt of choice.

Figure 17: Difference between KCl and NH₄Cl in regard of separation of ribosomal complexes. Sample preparation was performed as indicated in Figure 16. Input = 50 µg lysed mitochondria. Asterisk indicates residual signals from previous antibody decorations.

Next, the optimal salt concentration was determined. High salt concentrations are used to minimize unspecific protein-protein interactions and to dissociate translational factors from the bacterial ribosome (Goyal et al., 2017; Spitnik-Elson and Atsmon, 1969). In contrast to eukaryotic ribosomes, 70S ribosomes accept high salt concentrations while still keeping their integrity

(Schweet and Heintz, 1966). As the mammalian mitoribosome is closely related to the bacterial ribosome, higher salt concentrations were tested in order to improve the purification of mitoribosomes. To check whether 55S mitoribosomes can cope with high salt concentrations, mitoribosomal particles were separated by sucrose gradient ultracentrifugation in buffer containing either 100 mM NH₄Cl or 300 mM NH₄Cl. Using 300 mM NH₄Cl a loss of the 55S monosome together with an increase in free 39S and 28S particles was observed (Figure 17). As the mammalian mitoribosome was found to dissociate at higher salt concentrations, 100 mM NH₄Cl was finally used for further purifications.

Figure 18: Impact of salt concentration on mitoribosome stability. Sample preparation was performed as indicated in Figure 16. Input = 50 μ g lysed mitochondria. Proteins of mtLSU (mL44) and mtSSU (mS27) were quantified and the protein distribution across the gradient in comparison to the total protein level was calculated.

4.1.2.3 Impact of Mg²⁺ concentration on mitoribosome integrity

For isolation of mitochondria, buffers are often supplemented with EDTA in order to reduce protease activity by chelating Mg²⁺ and Ca²⁺ ions (Carroll, 2017). This chelating agent needs to be strictly avoided as it was shown already by (Lamfrom and Glowacki, 1962) that Mg²⁺ is required to maintain the structural integrity of 70S ribosomes. In contrast, high Mg²⁺ concentrations do not have a positive influence on translation in bacteria (Noah and Wollenzien, 1998). In order to determine the appropriate Mg²⁺ concentration for separating mitoribosomal complexes without dissociation of the 55S monosome, different Mg²⁺ concentrations were tested in buffers for mitochondrial lysis and sucrose gradient centrifugation. Isolated mitochondria were lysed in different buffers containing 20 mM, 10 mM, 8 mM, 6 mM, 4 mM or 2 mM MgCl₂. Ribosomal particles were separated by sucrose gradient centrifugation using the mentioned magnesium concentrations. The 55S ribosome was intact in the presence of 20 mM MgCl₂, 10 mM MgCl₂ or 8 mM MgCl₂. Using 6 mM MgCl₂ a slight reduction in the level of 55S ribosome in fraction 11 and 12 was detected, especially visible for the mtSSU protein mS27. Reducing the MgCl₂ concentration

further to 4 mM, the dissociation of 55S particles was even more pronounced and using 2 mM MgCl₂ 55S ribosomes were not detectable. Thus 8 mM MgCl₂ is required to prevent 55S dissociation and was used for further experiments

Figure 19: Impact of different Mg²⁺ concentrations on mitoribosome stability. Sample preparation was performed as indicated in Figure 16. Input = 50 µg lysed mitochondria.

4.1.2.4 Improvements on purity of starting material

Mitochondria are isolated as described in 3.2.3. These mitochondrial samples contain still contaminants such as endoplasmic reticulum (ER) and cytosolic proteins. The ER and mitochondria are in close relationship as reviewed by De Brito and Scorrano, 2010. Cytosolic ribosomes (80S) are bound to a portion of ER. An initial experiment was performed by Dr. Ricarda Richter-Dennerlein: mitochondria were isolated, lysed and the lysate was loaded on a 10-30% sucrose gradient. Obtained fractions were precipitated with ethanol and fractions 3-15 were analysed by mass spectrometry in the group of Prof. Dr. Henning Urlaub, Department of Bioanalytical Mass Spectrometry, Max Planck Institute for Biophysical Chemistry (Göttingen). Samples were subjected to LC/MS, analysed via MaxQuant (version 1.6.0.1) and LFQ (label free quantification) values were calculated. The LFQ intensity for each analysed fraction for two mitoribosomal proteins is plotted in Supp. Figure 1A. The 55S monosome is situated in fraction 9. For this reason, fraction 9 was further analysed (Supp. Table 1). In total, 805 proteins were

detected by MS analysis. Out of these, 72 of 82 mitoribosomal proteins were found with low abundance. In contrast, the sarcoplasmic/endoplasmic reticulum calcium ATPase 2 and the ER protein Calnexin were identified with higher abundances. In addition, 47 proteins of the cytosolic ribosome were detected. As beforehand mentioned, purified mammalian mitoribosomes are required for further analyses and thus contamination with 80S ribosomes needs to be minimized. A possibility to eliminate associated cytosolic ribosomes is to strip mitochondria from the outer membrane using low concentration of digitonin in order to produce mitoplasts (Spremluli, 2007). If the digitonin concentration is well chosen, the outer mitochondrial membrane (OMM) is disrupted and can be removed together with proteins of the inter membrane space (IMS) by Proteinase K treatment leaving the inner mitochondrial membrane (IMM) and the matrix still intact (Figure 20).

Figure 20: Difference mitochondrion and mitoplast.

In order to define the best digitonin concentration, mitochondria were isolated and treated with different concentrations of the detergent to rupture the OMM. Samples were incubated for 30 min and further subjected to Proteinase K treatment (0.5 μ g Proteinase K/100 μ g mitochondria). If just the OMM is disrupted but not the IMM, proteins of the matrix are shielded by the IMM from a Proteinase K digestion. If the samples are centrifuged afterwards for 5 min at 12000xg, mitoplasts are pelleted, separated from digested proteins of the OMM and IMS in the supernatant. Without digitonin treatment 80S proteins are pelleted together with mitochondria. Using 0.01%, 0.05% and 0.1 % digitonin the IMM protein TIM23 is still intact, but the OMM protein MFN2 is digested by Proteinase K as well as the ER marker Sec61 β and the 60S protein RPL3 (Figure 21A). Thus, under these conditions, the IMM of the mitoplasts stays intact while the OMM, ER and 80S ribosomes are removed. If the digitonin concentration is increased up to 0.2 %, the amount of proteins decreases in the mitoplast pellet suggesting that the IMM starts to get ruptured as well. Hence, mitoribosomal proteins in the matrix are also not protected well enough. Thus, for the preparation of mitoplasts 0.1% digitonin will be applied to 4 mg/ml mitochondrial suspension (protein:detergent = 4:1) followed by Proteinase K digestion with 5 μ g protease/ 1 mg protein.

Figure 21: A) Determination of digitonin concentration for preparation of mitoplasts. Mitochondria were isolated and treated with different concentrations of digitonin. Samples were treated with Proteinase K (PK) as indicated and subjected to centrifugation. P = pellet fraction, T = total sample. All samples were further analysed by SDS-PAGE and western blot with specific antibodies for mtLSU, cytosolic ribosomes, ER, IMM and OMM. B) Localisation of proteins tested in A).

Finally, mitoplasts prepared as described above, were lysed and loaded onto a 5-30% sucrose gradient to separate mitoribosomal particles. Obtained fractions were given to our collaborators for MS-analysis. LFQ intensities for all 16 fractions for 2 mitoribosomal proteins are shown in Supp. Figure 1B. Fraction 11 with the assembled 55S ribosome was further investigated (Supp. Table 2). By MS-analysis 510 proteins were identified in this fraction. Overall, 80 of 82 mitoribosomal proteins have been detected with a 10-fold enrichment to the previous experiment. In contrast, just 36 cytosolic proteins were identified and contaminations with ER proteins (e.g. Calnexin and sarcoplasmic/endoplasmic reticulum calcium ATPase 2) were strongly reduced.

The parameters for the separation of mitoribosomal complexes by density gradient centrifugation could be significantly improved. Using mitoplasts instead of crude mitochondria increase the purity of the starting material. The optimal buffer composition was determined with 100 mM NH₄Cl and 8 mM MgCl₂; and a sucrose gradient of 5-30% provides a reasonable separation in the lower dense fractions.

4.1.3 Mammalian mitoribosome isolation

4.1.3.1 Establishing a protocol for mammalian mitoribosome isolation

For the isolation of mitochondrial ribosomes from HEK293T cells, available protocols for bovine mitoribosome (Spremluli, 2007) and bacterial ribosome isolation (Rodnina and Wintermeyer, 1995) were tested and adjusted. First, mitoplasts from HEK293T cells were lysed in buffer containing 100 mM KCl, 20 mM MgCl₂, 20 mM HEPES/KOH pH 7.4, 3 mM β-mercaptoethanol, 1x protease inhibitor cocktail (Roche), 0.08 U/μl RiboLock RNase Inhibitor and 2 % digitonin (5 g digitonin:1 g protein). The lysate was subjected to centrifugation for 15 min at 20000xg to pellet the membrane fraction. The cleared lysate was loaded onto a 1 M sucrose cushion and ribosomes were pelleted using a SW41Ti rotor at 148,000xg for 15 h at 4°C. As the mitochondrial inner membrane comprises many large protein complexes, e.g. OXPHOS complexes, a lot of these were pelleted together with the mitoribosome. For subsequent separation of the 55S from the 28S and 39S, the sample was loaded onto a 10-30% sucrose gradient and centrifuged at 79,000xg for 15 h at 4°C using a SW41Ti rotor. Collected fractions were analysed by silver staining and western blotting (Figure 22).

Figure 22: Mitoribosome isolation. From initial 60 plates of HEK293T cells, 20.5 mg mitoplasts were isolated. A) Sample a = 5 % of crude mitoribosomes. The remaining 95 % were loaded onto the 10-30 % sucrose gradient. For analysis, 1% of fraction material was loaded on a 10-18% Tris-Tricine gel and a silver staining was performed. Fraction 9 was pelleted to enhance the ribosomal concentration. F9 = 10 % of pelleted fraction 9. B) To analyse the composition of the pelleted fraction 9, 30 % of the total F9 were separated again on a 10-30 % sucrose gradient. Samples were separated by SDS-PAGE followed by western blotting using specific antibodies against mitoribosomal proteins and possible contaminants. M=10 μg crude mitochondria.

Fractions corresponding to 55S ribosomal particles were pelleted. Within the fractions no distinct peaks corresponding to mtLSU, mtSSU or 55S were detectable. Sample A was taken after the sucrose cushion prior loading of the material on the sucrose gradient. A sample of the pelleted fraction 9 was also analysed. Mitoribosomal proteins have mostly a molecular weight of less than 50 kD. The silver staining of the pelleted fraction 9 showed many proteins with a higher molecular weight reflecting contaminations with non-ribosomal proteins potentially caused by the use of the mild detergent digitonin, which maintains other large mitochondrial complexes.

Therefore, different detergents for lysing mitoplasts were tested to increase the efficiency and to reduce other mitochondrial complexes. Initially, sodium deoxycholate was used as solubilizing agent in mitoribosome isolation protocols (O'Brien and Kalf, 1967). Unfortunately, this detergent tends to precipitate upon addition of MgCl₂ or other divalent cations (Rehm and Letzel, 2016). As the presence of Mg²⁺ ions is crucial for the integrity of 55S mitoribosomes (see Figure 19), sodium deoxycholate was not suitable to use. In the protocol for bovine mitoribosome isolation by Spremulli, 2007, 0.16 mg Triton X-100 for 1 mg protein was used for solubilisation. However, the solubilisation capacity of Triton X-100 has a saturation of 0.38 mg Triton X-100 per 1 mg protein (Nicholson and McMurray, 1986) and the solvent-to-protein ratio should be 2-4:1 for Triton X-100 (Rehm and Letzel, 2016).

Thus, 2.5 mg Triton X-100:1 mg protein and 5 mg digitonin:1 mg protein were compared for lysis. Mitoplasts (33 mg) were lysed in buffer containing 100 mM NH₄Cl, 8 mM MgCl₂, 20 mM Tris/HCl pH 7.5, 2 U DNase/5 mg protein, 10 μM CaCl₂, 0.5 mM TCEP and the respective detergent (1 % Triton X-100/2 % digitonin). The cleared lysate was loaded onto a 1 M sucrose cushion, centrifuged as described previously and further subjected to 5-30 % sucrose gradient ultracentrifugation to separate the ribosomal particles.

The absorption of nucleic acids at 260 nm corresponds to 12S and 16S rRNA of the mitochondrial ribosome and thus three peaks are expected for 28S, 39S and 55S within the gradient. By using digitonin, no well-defined peaks corresponding to the mitoribosomal particles were obtained (Figure 23A). In contrast, using Triton X-100 as detergent revealed clear and distinct peaks for 39S mtLSU and 55S monosome and higher A₂₆₀ values suggesting that more mitoribosomes were isolated (Figure 23B). Hence, Triton X-100 was further used as detergent for further experiments.

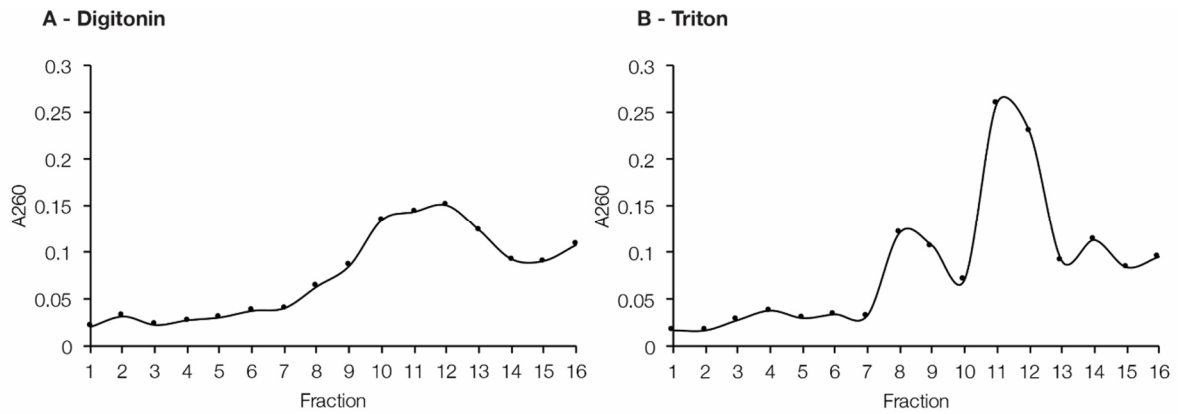

Figure 23: Mitoribosome isolation. Lysis of mitoplasts with 100 mM NH_4Cl , 8 mM MgCl_2 and A) 2 % digitonin B) 1 % Triton X-100. From all taken fractions, the absorption at A260 was measured and plotted over the fractions.

Since the crude ribosomal pellet was hard to dissolve a two-step sucrose cushion was applied to avoid pelleting (suggestion by Prof. Dr. Marina Rodnina). The mitoribosomes will accumulate in the interphase between 1 M and 1.7 M sucrose cushion. To check, whether the two-step sucrose cushion has an advantage over pelleting, both methods were compared.

After lysis of mitoplasts and subsequent centrifugation, proteins of the mitoribosome and other big complexes within the IMM are enriched in the supernatant fraction. Smaller portions are still in the pellet, besides residual amounts of cytosolic ribosomes, which were not completely removed by stripping of the OMM of mitochondria (Figure 24 A). The cleared lysate was loaded either A) onto a two-step sucrose cushion (20 ml sample/11 ml 1 M sucrose cushion solution/10 ml 1.67 M sucrose cushion solution) or B) on top of a single sucrose cushion (27 ml diluted sample/11 ml 1 M cushion solution) and centrifuged as described previously. The pelleted crude ribosome sample B was dissolved in wash buffer (100 mM NH_4Cl , 8 mM MgCl_2 , 20 mM Tris/HCl pH 7.5, 5 mM DTT) supplemented with 1 % DMSO. From the two-step cushion sample A the interlayer between the two sucrose cushions was taken and buffer exchange was performed by ultrafiltration using Amicon® Ultra-15 Centrifugal Filter Devices 100K (Merck).

Samples of the interlayer (A) showed mitoribosomal proteins, a reduction of YME1L, but still contaminations with PHB2. Even with a two-step sucrose cushion, some proteins pelleted - amongst them a bigger portion of YME1L but also mitoribosomal proteins. Samples of the resuspended pellet B showed no reduction in the level of YME1L meaning that other big complexes cannot be separated with this method.

Figure 24: Mitochondrion isolation comparing non-pelleting versus pelleting of crude ribosomes. Buffer conditions: 100 mM NH₄Cl, 8 mM MgCl₂, 1 % Triton. Mitochondria were isolated from 120 plates of HEK293T cells and in total 66 mg of mitoplasts were obtained. A) Samples during experiment. 0.1 % of SN/pellet = 0.1 % of supernatant/pellet after lysis of 66 mg mitoplasts. F9/11/11+12 = 33 % of final fraction 9/11/11+12. B) Simplified presentation of protein complex localisation. Protein distribution over sucrose gradient and absorption at A_{260} plotted over the fractions of the two-step sucrose cushion (C) and pelleted sample (D). M= 10 μ g crude mitochondria.

To improve the purity, both samples were subjected to a second sucrose cushion (A: two-step sucrose cushion: 6 ml sample/ 4.5 ml 1.1 M sucrose cushion/ 1.5 ml 1.75 M sucrose cushion; B: single sucrose cushion: 6.5 ml sample/ 4.5 ml 1.1 M sucrose cushion). Afterwards, the pelleted sample (B) was again dissolved in wash buffer containing 1 % DMSO or the two-step cushion sample (A) was ultra-filtrated for buffer exchange and sample volume reduction. Here, sample A showed a strong reduction of the PHB2 level. In contrast, the resuspended sample B was still contaminated with YME1L and PHB2. It has to be mentioned, that it was not possible to dissolve the pellet completely, as already described before. By analysing this non-soluble pellet, it became apparent that bigger portions of PHB2 and YME1L stayed insoluble together with mitoribosomal proteins. It can be concluded that substantial amounts of mitoribosomes get lost with this method.

To separate the crude mitoribosomes into 28S mtSSU, 39S mtLSU and assembled 55S complexes, samples were loaded on 5-30 % linear sucrose gradients, centrifuged and fractionated. For mitoribosomal fractions of sample A buffer exchange and sample volume reduction was applied by ultrafiltration. In contrast, 55S fraction of sample B was pelleted at 181,000xg for 6 h using a TLA55 rotor. The two-step sucrose cushion sample revealed well resolved peaks for 39S mtLSU and 55S monosome (Figure 24C). Proteins of the large and small mitoribosomal subunit are enriched in fraction 11, whereas RPL3 as cytosolic ribosome marker and PHB2 and YME1L as marker for other large mitochondrial protein complexes were not detected in contrast to 10 µg crude isolated mitochondria (Figure 24A). Based on the assumption by Spremulli, 2007, that 1 A_{260} equals 32 pmol of 55S, 4.5 nmol of 55S ribosomes were isolated from 33 mg mitoplasts. The Coomassie Blue staining revealed mainly proteins below 50 kD characteristic for mitoribosomal proteins. In comparison, by pelleting the material, the purification and separation of mitoribosomal particles was inefficient due to precipitations (Figure 24D). The 55S fractions 11 and 12 were combined, but from 33 mg mitoplasts just 1.4 nmol of 55S ribosomes were isolated, which is compared to the non-pelleted sample a loss in yield of 69 %. (Figure 24A). Although the purification of mitoribosomes over two two-step sucrose cushions improved the isolation efficiency significantly, the amount of lost material was still relatively high, thus for next isolations only one two-step cushion followed by a sucrose gradient was applied.

Finally, the sucrose gradient centrifugation step required optimization. With the help of Lukas Schulte and Uma Lakshmi Dakshinamoorthy from the laboratory of Holger Stark (Max-Planck-Institute for Biophysical Chemistry, Göttingen) by using their sucrose gradient estimator CowGraCE (Schulte, 2018) the sucrose gradient centrifugation was changed from 5-30 % linear sucrose gradient and 15 h run time at 79,000xg to 15-30 % linear sucrose gradient and 16 h 10 min run time at 115,605xg. With these settings the lowest overlap of subunit peaks and an optimal separation of the ribosomal particles was possible.

4.1.3.2 Final protocol for mammalian mitoribosome purification

After alteration of various parameters within the protocol for mitoribosome purification, the final strategy was applied:

Mitochondria were isolated from 98 plates of HEK293T cells as described in section 3.2.3. Mitoplasts were prepared by using 0.2 % digitonin (protein:detergent ratio 4:1) and 5 µg Proteinase K per 1 mg mitochondria. Following this, 68 mg mitoplasts were solubilized in a buffer containing 1 % Triton X-100, 100 mM NH₄Cl, 8 mM MgCl₂, 20 mM Tris/HCl pH 7.5, 5 mM DTT and membranes are separated by centrifugation. The cleared lysate was loaded onto a two-step sucrose cushion (20 ml sample/ 11 ml 1 M sucrose cushion solution/ 5 ml 1.75 M sucrose cushion solution) containing the same buffer conditions without detergent and centrifuged using a SW32Ti rotor for 15 h at 148,000xg at 4°C. Afterwards, the sample was fractionated and RNA and protein distribution over the fractions analysed (Figure 25A/B). Fraction 1-4 corresponded to material on top of the 1 M sucrose cushion after centrifugation, fraction 5 included the upper 2/3 of the 1 M sucrose cushion and fraction 6 the lower 1/3 of the 1 M sucrose cushion. Fraction 7 contained the interlayer between the two sucrose cushions and the complete 1.75 M sucrose cushion without the small pellet on the bottom. Within this pellet proteins of large complexes like *i*-AAA (YME1L) protease and Prohibitins (PHB2) were detected, but just smaller portions of mitoribosomal proteins. Mitoribosomes were enriched in fraction 7 and this material was subjected to ultrafiltration using Amicon® Ultra-15 Centrifugal Filter Devices 100K (Merck) in order to reduce the sucrose concentration and the sample volume. Within the ultrafiltration, some material pelleted in the filter devices (sample PA) and was analysed. A similar protein composition as in the pellet after the two-step sucrose cushion was detected (sample PS).

The cleared crude mitoribosome sample was subjected to 15-30 % linear sucrose gradient ultracentrifugation using a SW41Ti rotor at 115,605xg for 16 h 10 min at 4°C. Collected fractions corresponding to 28S, 39S and 55S particles were concentrated and sucrose removed by ultrafiltration with Amicon® Ultra-4 Centrifugal Filter Devices 100K (Merck). The RNA profile of the fractions revealed well separated distinct peaks for mitoribosomal particles (Figure 25C). The Coomassie Blue staining showed protein bands mainly below 50 kD corresponding to mitoribosomal proteins which have mainly a molecular weight less than 50 kD (Figure 25B). Immunodetection of proteins of the mitoribosome showed a clear enrichment in comparison to a 10 µg mitochondria control in contrast to RPL3, YME1L and PHB2.

Figure 25: Mammalian mitoribosome isolation. 68 mg mitoplast were lysed and loaded onto a two-step sucrose cushion. From a total sample plus cushion volume of 36 ml, per fraction 20 μ l were analysed via SDS-PAGE (A). B) Samples during experiment analysed via SDS-PAGE followed by Coomassie Blue staining and western blotting: 0.1 % of SN/pellet = 0.1 % of supernatant/pellet after lysis. 1 % of PS/PA/SN, PS = resuspended pellet after centrifugation, PA = resuspended pellet from Amicon filter, SN = crude mitoribosomes. From the finally purified ribosomal samples were analysed: 9 % of fraction 7 (F7), 7 % of fraction 9 (F9) and 8 % of the combined fraction 12/13 (F12/13). M = 10 μ g crude mitochondria C) A total of 1% per fraction was analysed. Protein and RNA distribution over sucrose gradient are visualized.

To check the final purity of the isolated 55S monosomes, 5 μl of sample (633 pmol of 55S) were analysed by mass spectrometry, which was performed by Dr. Andreas Linden, Department of Bioanalytical Mass Spectrometry headed by Prof. Dr. Henning Urlaub, Max Planck Institute for Biophysical Chemistry (Göttingen). Purified 55S mitoribosomes were subjected to LC/MS, analysed via MaxQuant (version 1.6.0.1) and iBAQ values were calculated (Supp. Table 3). Finally, 82/82 mitoribosomal proteins were detected and most of them with a high abundance. However, 62 of 80 cytosolic ribosomal proteins were measured as well, but with a much lower abundance.

Figure 26: Flowchart mammalian mitoribosome isolation.

In conclusion, a protocol for mitoribosome isolation from HEK293T cells was successfully established and the final strategy is visualized in the flowchart (Figure 26). In total, from 98 plates of HEK293T cells 188 mg of mitochondria were obtained. By further processing, 68 mg of mitoplasts were isolated. Finally, 30 nmol of 28S mtSSU from fraction 7, 74 nmol of 39S mtLSU from fraction 9/10 and 34 nmol of 55S ribosomes from fraction 12/13 were isolated.

For the quantitative mass spectrometry approach of the assembly of the mitoribosome, lightly labelled 55S mitoribosomes were isolated as standard for 240 gradient fractions (5 time points, 16 fractions each, $n = 3$). In total, 251 nmol mitoribosomes were purified, which was sufficient to add 633 pmol of 55S ribosomes into each fraction. The final experiment was performed together with Elena Lavdovskaia and MS analysis is currently performed by Dr. Andreas Linden. The data analysis is still ongoing and will shed new light into the biogenesis of the mitochondrial ribosome.

4.1.4 Discussion

Within this thesis, a new purification procedure has been established to obtain 55S human mitoribosomes from HEK293T cells different from the already published protocols (Aibara et al., 2018; Carroll, 2017; O'Brien and Kalf, 1967; Spremulli, 2007). The first mitoribosomes were isolated from rat liver (O'Brien and Kalf, 1967). Additionally, mitoribosomes were obtained from livers of *Bos Taurus* or *Sus scrofa* (Greber et al., 2014b; Spremulli, 2007) or HEK293T cells (Aibara et al., 2018; Brown et al., 2014).

The buffer conditions needed to be taken into careful consideration and parameters had to be adjusted as each component can be crucial for the integrity of the 55S mitoribosome. Of special importance is the type of salt used in purification buffers. As already described by Carroll (2017) salts within the buffers are required to stabilize the ionic strength, by reducing unspecific protein-protein interactions in order to keep the integrity of the ribosomes. Using sodium chloride for bacterial ribosome isolation, no 70S ribosomes are obtained (Beller and Davis, 1971; Hardy and Turnock, 1971; Phillips et al., 1969). As mitoribosomes evolved from bacterial ribosomes it is reasonable to avoid this salt in buffers for mitoribosome purification (Carroll, 2017). Various protocols for mitoribosome isolation use potassium chloride in a range of 50-100 mM in purification buffers (Aibara et al., 2018; Brown et al., 2014; Carroll, 2017; Greber et al., 2014b; O'Brien and Kalf, 1967; Spremulli, 2007). In contrast, ammonium chloride is usually used for bacterial ribosome isolation. It was shown that bacterial ribosomes are more active in presence of NH_4Cl instead of KCl (Zamir et al., 1971). The same was stated for 74S yeast mitoribosome (Pfisterer and Buetow, 1981). Thus, KCl was replaced by 100 mM NH_4Cl and the stability of assembled 55S complexes were analysed. By using ammonium chloride, a better separation of mitoribosomal particles and a well resolved monosome peak was obtained. However, the activity of the purified mitoribosomes was not investigated and requires further analyses.

Bacterial 70S ribosomes are able to keep their integrity in a wide range of salt concentrations other than eukaryotic 80S ribosomes which aggregate (Schweet and Heintz, 1966). Conversely, for dissociation of 80S ribosomes from peas 500 mM NH_4Cl can be used (Lin et al., 1975). If high salt concentrations are applied to 50S bacterial ribosomes, translational factors dissociate (Goyal et al., 2017). In a well-established protocol from Rodnina and Wintermeyer, 1995, 500 mM NH_4Cl are used within the 1.1 M sucrose cushion for 70S bacterial ribosome purification leading to the question whether an improvement of 55S mitoribosome isolation with higher salt conditions is possible. Apparently, 300 mM NH_4Cl lead to a drastic reduction of 55S monosome and increased levels of 39S and 28S. Mammalian mitoribosomes seems to be unstable under high salt conditions

and dissociate into their subunits. In conclusion, just 100 mM NH₄Cl were used for purifications. However, higher salt concentrations could be considered to isolate dissociated subunits.

To purify assembled 55S mitoribosomes the concentration of Mg²⁺ ions in preparation buffers has to be carefully evaluated. Already Lamfrom et al. stated in 1962 that 70S ribosomes dissociate in absence of Mg²⁺ ions. However, high concentrations of Mg²⁺ ions do not have a positive influence on 70S ribosomes (Carroll, 2017; Noah and Wollenzien, 1998). Carroll (2017) suggested 10-20 mM Mg²⁺ to be added in buffers for mitoribosome purifications. Spremulli (2007) used buffers including 20 mM MgCl₂ for purification of 55S ribosomes and buffers including 2 mM MgCl₂ for purification of ribosomal subunits. Therefore, magnesium concentrations were tested in a range from 2 mM to 20 mM for suitability in mitoribosome purification. As high magnesium concentrations might have negative effects on mitoribosomes (statement by Prof. Dr. Marina Rodnina), the magnesium concentration was titrated to a minimum. The best yield of 55S monosomes was obtained using 8 mM MgCl₂. If the magnesium concentration was lower than 6 mM, the 55S started to dissociate into 39S and 28S subunits.

To reduce contaminations with 80S cytosolic ribosomes purified mitoplasts were used instead of crude isolated mitochondria for mitoribosome purification, which is in contrast to other published protocols (Brown et al., 2014; Greber et al., 2014a; O'Brien and Kalf, 1967). The biggest difference between all other procedures and the one described here is the avoidance of pelleting ribosomes. Instead, the interlayer between a two-step sucrose cushion was used where the mitoribosomal fraction is enriched. This improved the yield and the quality of purified mitoribosomes in the end as confirmed by mass spectrometry. Although the purification strategy shows an improvement compared to the already published protocols, the activity of the isolated mitoribosomes needs to be investigated in the future.

4.2 Characterization of the disease associated protein mL44 and the membrane anchor mL45 within the biogenesis of the human 39S mtLSU

The mammalian mitoribosome consists of 82 proteins, amongst these 50 proteins belonging to the 39S mtLSU (Greber and Ban, 2016). This doctoral work focuses on the assembly of the 39S mtLSU. To shed light into this, two different proteins of the mtLSU were further characterized – the disease associated mL44 and the mitoribosomal membrane anchor mL45.

4.2.1 Influence of the disease associated mitoribosomal protein mL44 on 39S mtLSU biogenesis

4.2.1.1 Introduction

The mitochondria-specific mL44 was shown to be an integral protein in the structure of the large subunit of the porcine and human mitoribosome (Brown et al., 2014; Greber et al., 2014a). mL44 is situated in proximity to the polypeptide exit tunnel, but not as close as in yeast where this protein directly forms the tunnel exit together with uL22m, uL23m, uL24m and mL50 (Bieri et al., 2018). Recently it was suggested that mL44 is incorporated early in assembly together with bL20m, bL21m, mL42 and mL43 (Bogenhagen et al., 2018). Also in yeast, mL44 is assembled early (Zeng et al., 2018).

As already mentioned in section 2.3, mL44 is a disease-associated protein. Carroll et al. described in 2013 two patients with infantile cardiomyopathy. Exome sequencing revealed a mutation in the *Mrpl44* gene at position c.467T>G (p.Leu156Arg) in both patients, predicted to giving rise to an improper folded mL44 protein. Further biochemical analyses uncovered a combined respiratory chain deficiency of complex I and IV for patient 1 in heart and skeletal muscle, whereas complex II and III were not affected. For patient 2 they showed just reduced levels of complex IV in fibroblasts. Hence, they suggested that the mL44 mutation affects OXPHOS complexes in a tissue specific manner. The authors suggested that in patient fibroblasts, the assembly of the 39S mtLSU was impaired. However, assembly intermediates were not visible and mitochondrial translation was comparable to WT. Consequently, the authors hypothesized that mL44 is required for the stability or assembly of the newly synthesized mtDNA-encoded proteins (Carroll et al., 2013).

Distelmaier et al. identified in 2015 another two unrelated patients with hypertrophic cardiomyopathy caused by mL44 deficiency. One of their patients had in addition to the previous reported homozygous mutation a heterozygous variation at position c.233G>A (p.Arg78Gln). Patient 1 showed in fibroblasts an isolated complex IV defect and patient 2 in heart tissue a

moderate complex I and a severe complex IV deficiency. These data support Carroll's et al. suggestion that mutated mL44 gives rise to a tissue specific phenotype (Distelmaier et al., 2015).

Carroll et al. speculated that the structural important mL44 is not directly required for *de novo* synthesis of mtDNA encoded proteins. However, siRNA mediated depletion of mL44 revealed a reduction in [³⁵S]Methionine *de novo* mitochondrial protein synthesis. To clarify this discrepancy and to define the role of mL44 in mtLSU biogenesis and mitochondrial translation mL44 was characterised in more detail in the next sections.

4.2.1.2 Impact of loss of function of mL44

To understand the function of mL44 and to assess the order of protein binding during mtLSU assembly, the consequences of loss of function of mL44 were investigated. Therefore, the HEK293T mL44^{-/-} cell line obtained from Dr. Ricarda Richter-Dennerlein was further characterized. By applying CRISPR/Cas9 technology using the guide RNA [AAGCTGGTCCCTCCGGTTCG] the knock-out cell line was generated according to Ran et al., 2013. Sequence analysis of the knock-out cell line using TOPO[®] sequencing as described in 3.2.1.10 unveiled three different mutations (Figure 27). Each mutation was leading to a frameshift resulting in a premature stop codon and the presence of truncated versions of mL44. Instead of the normal length mL44 protein comprising 332 aa (amino acids), the mutated forms consisted of only a) 30 aa, b) 89 aa and c) 89 aa.

Figure 27: Sequence analysis of mL44^{-/-} cell line. The coding sequence of mL44 consists of 996 bp (base pairs). WT = wild type sequence of MRPL44. a) Mutation allele 1: mL44_c.61_71del b) Mutation allele 2: mL44_c.65_66+68_76del c) Mutation allele 3: mL44_c.69del.

To analyse the impact of mL44 ablation on mitochondrial *de novo* protein synthesis, a [³⁵S]Methionine labelling was performed as described previously (3.2.2.4). In the mL44^{-/-} cell line a complete depletion of mitochondrial translation was observed compared to wild type (WT), even if residual amounts of mL44 protein were detected (Figure 28). In order to show that defects are specific due to the loss of mL44 and not caused by an off-target effect, a rescue cell line was generated. The mL44^{-/-} cell line was transfected with pOG44 and pcDNA5/FRT/TO encoding a C-terminal FLAG tagged variant of mL44. Clones with successful integration of mL44^{FLAG} into the Flp-In cassette were selected with hygromycin. For convenience, this cell line is called mL44^{-/-}R. The expression of exogenous mL44^{FLAG} and mitochondrial translation competence was tested by [³⁵S]Methionine *de novo* synthesis and subsequent western blotting. The expression of mL44^{FLAG} completely restored the translation phenotype indicating that the knockout is specific, and the FLAG tagged variant of mL44 is also functional. Thus, mL44 is required for mitochondrial translation.

Figure 28: Loss of mitochondrial translation in mL44^{-/-} cells. Mitochondrial translation was tested by the incorporation of [³⁵S]Methionine into *de novo* synthesized mtDNA-encoded proteins while cytosolic translation was blocked with emetine. Samples (50 µg) were analysed by SDS-PAGE followed by autoradiography (upper panel) and western blotting (lower panel). GAPDH was used as a loading control. WT: HEK293T wild type, mL44^{-/-}R: mL44^{-/-}-expressing mL44^{FLAG} (n=3).

Depletion of mL44 leads to a complete loss of mitochondrial translation suggesting that the function or biogenesis of the mitoribosome is disturbed. To dissect the consequences of mL44 loss further, protein steady state levels of mitoribosomal proteins and assembly factors were tested by western blotting. If mL44 is missing, most protein levels of the tested LSU proteins were diminished (uL1m, uL3m, bL20m, bL21m, uL23m, mL39, mL45, mL62) or even not detectable (uL13m). One of the tested proteins, uL10m, remained stable whereas bL12m was even

upregulated (Figure 29). Surprisingly, ablation of mL44 leads to reduction of some mtSSU proteins (uS14m, mS22, mS25), no change in mS27 level and increase in uS7m. All tested assembly factors were also decreased (GTPBP7, GTPBP10, MALSU1, NSUN4).

Figure 29: Protein steady state analysis of cell lysates obtained from HEK293 WT cells, HEK293T mL44^{-/-} cells or HEK293T mL44^{-/-}R. A, B) Cell lysates (50 μg) were tested by western blotting using antibodies against MRPs of the mtLSU and mtSSU, and of assembly factors (AF). Calnexin was used as a loading control. * indicates residual signals of preceding antibody decorations. C) Protein levels in mL44^{-/-} were quantified using ImageQuant TL software and calculated relative to wild type (WT).

To analyse whether mitoribosomes or subcomplexes are formed in the absence of mL44, mitoplast lysates were separated by sucrose gradient ultracentrifugation. For all tested mitoribosomal proteins of the mtLSU, no assembled 39S mtLSU and 55S particle were detected (Figure 30A). In contrast, 28S mtSSU assembly seemed to be unaffected (Figure 30B). The level of assembled 28S is higher than in WT control, as 28S is not used to form monosomes (Figure 30D). All tested assembly factors accumulate upon ablation of mL44 in the lower dense fractions (Figure 30C).

Figure 30: Effect of mL44 ablation on mitoribosome biogenesis. Lysates of 500 μ g mitoplasts isolated from HEK293T WT, HEK293T mL44^{-/-} or HEK293T mL44^{-/-}R were separated on 5-30% sucrose gradients, fractionated and analysed via SDS-PAGE and immunostaining of mitoribosomal proteins (A, B) and assembly factors (AF, C). D, E) Quantification of bL20m and uS15m across sucrose gradient for comparison of WT and mL44^{-/-} using the software ImageJ. M = 10 μ g HEK293T WT mitochondria, 10 % Input of loaded material = 50 μ g lysed mitoplasts. (n=3)

Assembly intermediates accumulated in the lower dense fractions in absence of mL44. For better visualization of this effect, one protein of the mtLSU, bL20m, was quantified across the gradient (Figure 30E). Differences in signal patterns of proteins are corresponding probably to more than one assembly intermediate. For uL1m, bL32m, mL45 and mL62 signals in fraction 1 and 2 of the sucrose gradient were detected. These could correspond to very initial subparticles or to a free pool of these proteins. The behaviour of mL45 and its interaction partners will be discussed in

section 4.2.2. No signals close to the position of 39S particle in WT control were observed upon mL44 ablation corresponding to nearly complete assembled mtLSU. These data provide evidence that mL44 is binding early in assembly.

The protein distribution of uL10m and bL12m in the lower dense fractions showed a similar pattern. As cross-linking mass spectrometry experiments revealed inter-protein crosslinks between uL10m and bL12m (Greber et al., 2014b), we suggest that they form a subcomplex. Future analyses are required to define this complex.

In conclusion, mtLSU and monosome assembly is mL44 dependent, whereas mtSSU assembly is independent of mL44. Together with data from steady state analysis it is shown that mL44 loss is leading to a destabilization of mtLSU. Many of the tested mtLSU proteins show signals in the lower dense fractions corresponding to early assembly intermediates or distinct submodules.

4.2.1.3 Characterization of an early assembly intermediate containing mL44

bL20m, bL21m, uL23m and uL24m showed a protein distribution in the sucrose gradient similar to mL44 in WT (Figure 30A). Nevertheless, the question remained whether they all form one complex together with mL44 or whether there are distinct small assembly intermediates. To answer this question, FLAG-immunoprecipitation experiments followed by sucrose gradients were performed according to 3.2.5. Therefore, the HEK293T mL44^{-/-}R cell line was used. As expected, using mL44^{FLAG} as a bait, which is a structural component of the 55S ribosome, assembly intermediates containing mL44, as well as fully assembled mtLSU and monosome were co-immunoprecipitated. This is illustrated by the co-isolation of proteins of the 39S mtLSU (bL20m, bL21m, mL45, mL62) and 28S mtSSU (uS14m, mS25, mS27) as well as one tested assembly factor (GTPBP10) (Figure 31A). Specifically, bL20m, bL21m and GTPBP10 were enriched in the elution fraction, suggesting the presence of an assembly intermediate.

To test this hypothesis further, eluates of FLAG-immunoprecipitation experiments were subjected to sucrose gradient centrifugation. Besides signals in fractions corresponding to 39S and 55S particles, also an assembly intermediate in the lower dense fractions was observed (Figure 31B, C). mL44 is interacting with bL20m, bL21m and GTPBP10 but not with uL23m, uL24m as previously suggested. To dissect the composition of this subcomplex detected in fraction 2 and 3 further, samples were analysed by mass spectrometry in the group of Prof. Dr. Henning Urlaub, Department of Bioanalytical Mass Spectrometry, Max Planck Institute for Biophysical Chemistry (Göttingen). Samples were subjected to LC/MS, analysed via MaxQuant (version 1.6.0.1) and iBAQ values were calculated (Supp. Table 4) by Dr. Andreas Linden. The proteins mL43, mL42, bL21m, bL20m and mL50 were detected with a high abundance, suggesting that they interact with mL44 in this subcomplex. GTPBP10 was detected as well, but with a lower abundance. The results of the

sucrose gradient experiments and MS-analysis (Figure 30A and Figure 31B, C) indicate that there are distinct early assembly intermediates, of which uL23m and uL24m seem to build another subcomplex without mL44.

Figure 31: Interactome of mL44. A) Isolated mitochondria (1 mg) from HEK293T WT (negative control) and mL44^{-/-R} cells were used for FLAG-co-immunoprecipitation. Analysis of samples by SDS-PAGE and western blotting using the indicated antibodies against mtLSU, mtSSU and assembly factors (AF). To exclude unspecific protein binding during IP, SDHA was used as negative control. Total = 3 % of mitochondrial lysate prior IP, Eluate = 100% of immunoprecipitated sample (n=3) B, C) Isolated mitochondria (B: 3 mg, C: 2.4 mg) were lysed, subjected to FLAG-co-immunoprecipitation and mitoribosomal particles further separated by 5-30% sucrose density gradient centrifugation. Analysis of samples by immunoblotting. Total = 1 % of FLAG-IP input, Eluate = 20 % of FLAG -IP eluate. Asterisk indicate residual signals from previous antibody decorations.

4.2.1.4 Stability of mitoribosomal proteins

As already described in chapter 2.1.4.2 a subset of Met-tRNA^{Met} is formylated. After progression of translation, this initial formyl group is cleaved by the enzyme peptide deformylase (Pdf). The drug actinonin can prevent this cleavage by inhibition of Pdf (Lee et al., 2004). It was already shown that treatment of cells with 150 μ M actinonin leads to a reversible, time dependent depletion of MRPs, 12S rRNA and 16S rRNA (Richter et al., 2013). However, the authors showed the effect of actinonin just for two MRPs: uL13m and uS15m. To get further insights into the stability of other MRPs, HEK293T WT cells were seeded and treated for different periods of time with 150 μ M actinonin.

Figure 32: Influence of actinonin on steady state levels of proteins of A) mtLSU B) mtSSU and AFs. Cells were treated with 150 μ M actinonin, harvested at distinct time points as indicated, lysed and analysed via SDS-PAGE and western blotting. Quantification of protein levels relative to untreated control was performed using the software ImageJ ($n=3$, mean \pm SEM). GAPDH served as loading control. The half-life of the adjacent proteins was determined as the time until the initial protein levels have been depleted by 50%. (Supp. Figure 2). Asterisks indicate unspecific antibody signals.

Actinonin treatment of cells lead to a decrease in protein levels of all tested proteins of mtLSU, mtSSU and AFs (Figure 32). However, some proteins were more stable than others. After 19 h still 50 % of the uL1m protein level was detectable. Also, mL44 was more stable than uL3m, uL23m, mL62, uL13m and mL54. However, the most stable protein was mS27. Within the tested time frame just a reduction of 40 % from the initial protein level was observed (Figure 32B, Supp. Figure 2) suggesting that it has crucial functions within mitochondria and consequently is required to be more stable.

4.2.1.5 Discussion

mL44 is a mitochondria specific ribosomal protein with no homologues in bacterial and cytosolic ribosomes. It is a protein consisting of 332 amino acids, of which the first 30 N-terminal residues probably serve as targeting signal for mitochondrial import. Within its structure two domains are predicted: a RNase III-like domain and a double-stranded RNA-binding domain (Carroll et al., 2013). However, the residues important for RNase function are not present in mL44. Hence, it is most likely not performing the function of RNase III, which is observed in prokaryotes (Koc et al., 2001).

By using for the first time a mL44^{-/-} cell line, it was shown in this doctoral thesis that mL44 is required for the assembly of the 39S mtLSU. In contrast, absence of mL44 has no impact on 28S mtSSU assembly. This is in agreement with data provided from Carroll et al., 2013. Within the investigated patient cell lines, the authors suggested an assembly defect of the mtLSU as well. The underlying mutation in those patients was identified as a substitution of leucine at position 156 to arginine. Structural analyses revealed that this specific leucine is surrounded by other hydrophobic amino acids, building a “hydrophobic pocket” (Brown et al., 2014). Due to incorporation of the basic amino acid arginine, they hypothesized that the mutation prevents binding of mL44 to the 39S due to its changed structure. However, even if Carroll et al. described “a dramatic loss” of mtLSU in their patient cell line, still substantial amounts of LSU proteins uL13m and mL44 were detectable by western blot analyses, suggesting the presence of a pool of 39S. This could be the reason, why no translation defect was observed. One can hypothesize that these residual mitoribosomes are capable of translation.

Mutational analyses of yeast mitoribosomes revealed that mL44 is an essential protein for mitochondrial protein synthesis in *S. cerevisiae* (Zeng et al., 2018). By creating a mL44 deletion strain the authors observed a significant loss of 21S rRNA implying an important structural role of mL44 within the yeast 74S ribosome. As shown in this doctoral study, *de novo* synthesis of mtDNA-encoded proteins in human cells was completely abolished upon loss of mL44 (Figure 28)

giving evidence that mL44 is a structural component of the 39S mtLSU and indeed required for functional translation similar to the yeast mL44 homologue.

In our analyses, upon ablation of mL44 most mtLSU proteins were diminished (Figure 29). The upregulated or stable mitoribosomal proteins are fulfilling most likely other functions within the cell. uL10m was described to act on cyclinB1/Cdk1 activity and thereby influencing cell growth (Li et al., 2016). By binding of bL12m on POLRMT it increases mitochondrial transcription and it was hypothesized that bL12m is part of a feedback loop for coordination of mitochondrial gene expression and ribosome biogenesis (Nouws et al., 2016; Surovtseva et al., 2011; Wang et al., 2007). mS27 is a pentatricopeptide repeat domain (PPR) protein and was suggested to be a translational regulator (Davies et al., 2012). An additional role of the disease associated protein uS7m was not described until now, but it might have also another function, as it is not depleted in the mL44^{-/-} cell line. One can hypothesize that cells are trying to cope with the loss of mL44 and therefore upregulating transcriptional activators as bL12m.

Upon actinonin treatment of cells, all tested proteins were diminished (Figure 32). One of the least reduced proteins was uL1m, which was described as part of the flexible L1 stalk in the porcine structure of the 39S mtLSU (Greber et al., 2014a). Nevertheless, its exact localization was not resolved until now. In bacteria, the L1 stalk was indicated to facilitate translocation of tRNAs from the P- to the E-site (Fei et al., 2008). Brown et al. (2014) were able to show in their cryo EM structure of the human mtLSU that parts of the E-site tRNA interact with the L1 stalk, suggesting a similar role for the mitoribosomal L1 stalk as for the bacterial. Probably, uL1m is protected by surrounding structures as the bacterial L1 shown by Nikulin et al., 2003 and reacts for this reason less sensitive upon treatment with actinonin. Another hypothesis for enhanced stability of uL1m would be that it fulfils additional functions within mitochondria as described for mS27, which was the most stable protein during actinonin treatment.

By comparing the half-life of proteins after treatment with actinonin, it became apparent that also mL44 was not as strongly affected by this drug as other proteins. Why does mL44 seem to be more stable? Structurally it is located quite exposed to the surface, in close proximity to the polypeptide exit tunnel (Brown et al., 2014; Greber et al., 2014a). As exemplified for other mitoribosomal proteins as bL12m (Nouws et al., 2016; Surovtseva et al., 2011; Wang et al., 2007), it might be that mL44 has a dual function that requires a higher stability.

Upon ablation of mL44, especially uL13m was not detectable. During actinonin treatment, uL13m was also very unstable. It is located in close proximity to mL44, facing the matrix (Brown et al., 2014). uL13m does not show signals in lower dense fractions in WT sucrose gradient analyses

(Figure 17). For this reason, it is suggested not to be part of an early submodule. Loss of mL44 seems to destabilize uL13m. No interaction of mL44^{FLAG} with uL13m in fraction 2/3 of sucrose gradients after co-immunoprecipitation experiments was observed despite their adjacent localization (Figure 31B). For this reason, one might assume that mL44 has to be assembled prior uL13m incorporation. This is in agreement with Bogenhagen's assembly map of the 39S mtLSU.

Additionally, mL44 interacts directly with bL20m, bL21m, uL22m, mL42, mL43, mL50 and mL51 (Brown et al., 2014). The steady state levels of bL20m and bL21m were determined in absence of mL44. Both proteins showed reduced levels, but not as strong as uL13m. bL20m and bL21m are located in close proximity to mL44 (Figure 33). For bL20m inter-protein crosslinks to mL44 were described (Greber et al., 2014b).

Figure 33: Structure of human 39S mtLSU visualized with UCSF Chimera (PDB: 3J7Y). 16S rRNA (dark grey), bL20m (orange), bL21m (yellow), mL42 (brown), mL43 (salmon), mL44 (red), mL50 (dark red).

In bacteria, bL20 and bL21 are components of the first submodule which is bound to the 23S rRNA. Subsequently, uL13 binds to bL20 (Chen and Williamson, 2013; Nierhaus and Dohme, 1979). Within human mitochondria, bL20m and bL21m were found to be in a complex together with mL44 (Figure 31B). Dissecting this complex by mass spectrometry the mitochondria-specific ribosomal proteins mL42, mL43 and mL50 were identified, indicating that binding of uL13m to

the growing mtLSU is not only dependent on the presence of bL20m, but on the previously formed subcomplex consisting of bL20m, bL21m, mL42, mL43, mL50 and mL44.

Additionally, to bL20m, bL21m, mL42, mL43 and mL50 in the submodule of mL44, the assembly factor GTPBP10 was detected (Figure 31B). In contrast, presence of uL23m and uL24m was excluded (Figure 31C). Inter-protein cross links between mL45 and uL23m as well as uL24m, but not with mL44 were observed by Greber et al., 2014b. Within the structure of the 39S mtLSU, uL23m and uL24m are further apart from mL44 suggesting the presence of distinct mtLSU assembly modules. However, the question remains whether there is really an interaction of GTPBP10 with the mL44 subcomplex. The assembly factor GTPBP10 acts late during mtLSU biogenesis, probably having a function in quality control (Lavdovskaia et al., 2018; Maiti et al., 2018). Elena Lavdovskaia (PhD student in the GGNB program Molecular biology of cells) provided evidence that GTPBP10 is interacting with other late assembly factors like MALSU1, MTERF4 and NSUN4. Pull-down experiments using GTPBP10^{FLAG} as bait followed by sucrose gradient analysis revealed no interaction with mL44 in the early dense fractions. Interactions of GTPBP10 with this early assembly intermediate might be very transient and for this reason not easy to detect. The bacterial homologue of GTPBP10 ObgE is interacting with the peptidyl transferase centre on the 50S LSU (Feng et al., 2014). However, ObgE has a second homologue in humans called GTPBP5 (OBGH1) (Hirano et al., 2006). As the peptidyl transferase centre of 55S mitoribosomes is evolutionary conserved, it can be speculated that one ObgE homologue could also bind in its proximity. As it was implied that GTPBP5 is involved in PTC maturation late during mtLSU biogenesis, a localisation of GTPBP5 close to the PTC would be required (Maiti et al., 2020). Hence, GTPBP10 might interact with the mtLSU at a different structure. However, to finally answer the question whether an interaction of GTPBP10 and mL44, situated in the shell of the 39S mtLSU, would be structurally possible, structural analyses using cryo-EM or protein-protein cross linking approaches would be beneficial.

The assembly factors NSUN4 and MALSU1 do not interact with the early mL44 assembly intermediate. This is not surprising as both were found to fulfil their function late in ribosome biogenesis (Brown et al., 2017; Metodiev et al., 2014). In addition, MALSU1 is binding to uL14m at the intersubunit interface of the mtLSU, which is on the opposite site of mL44 (Brown et al., 2017).

Carroll et al, 2013 proposed that the homozygous mutation identified in their patients was leading to instability of mL44. However, reduced amounts of 39S mtLSU were still detected in the patient derived cell lines. In contrast to the complete loss of uL13m in the mL44^{-/-} cell line shown in this doctoral study, uL13m was just diminished in patient fibroblasts. By comparing the protein steady

state levels of different mt-encoded proteins of the respiratory chain, Carroll et al. detected a more severe phenotype in heart and skeletal muscle cells in contrast to fibroblasts of patients. One can hypothesize that this could be due to differences in the energy demand of various cell types, as high energy demanding tissues are usually more severely affected by mitochondrial disorders (Frazier et al., 2019).

In order to understand the effects of the L156R mutation in the *Mrpl44* gene on 39S mtLSU biogenesis and the interaction of mutated mL44 to other MRPs, a cell line was generated via site-directed mutagenesis containing the mutated form of mL44. This cell line should serve as a tool to explore the effect of the L156R mutation within mL44. Will this mutated protein still interact with bL20m and GTPBP10? Will there be an accumulation of the assembly intermediate containing mL44^{L156R}? To answer these questions, this cell line is currently analysed by Venkatapathi Challa, a PhD student in the research group of Dr. Ricarda Richter-Dennerlein. Using the mL44^{L156R} cell line, the mt translation will be examined to clarify the discrepancy between the unaffected mitochondrial *de novo* synthesis of proteins observed in patient fibroblasts and the severely depleted translation in mL44^{-/-} cells.

4.2.2 Dissecting the role of the membrane anchor mL45 in mitoribosome biogenesis

4.2.2.1 Introduction

Like mL44, mL45 is a mitochondria specific ribosomal protein without having a homologue in bacteria (Greber et al., 2014b). mL45 contains a TIM44-like domain on its C-terminus, which is oriented on the mtLSU similar to the membrane binding structure of TIM44 itself. In addition, mL45 shows homologies to the yeast mitoribosome membrane anchor Mba1 (multi-copy bypass of AFG3 protein), suggesting that mL45 is mediating the contact between the 55S mammalian mitoribosome and the IMM (Figure 34) (Greber et al., 2014b).

Figure 34: Localisation of mL45. Proteins are labelled by using the old mitoribosomal nomenclature. MRPL39 = mL39, MRPL44 = mL44, MRPL45 = mL45. Picture taken from Greber et al., 2014b. DOI: <https://doi.org/10.1038/nature12890>

This assumption was confirmed in 2017 by the group of Prof. Dr. Friedrich Förster. They were able to show that the 55S ribosome is anchored by mL45 via cryoelectron tomography (Englmeier et al., 2017). In contrast to the mitoribosome of *Saccharomyces cerevisiae*, the mammalian mitoribosome is connected to the IMM only by one contact. The second contact which is built through a rRNA interaction with the IMM in yeast, is missing in human (Englmeier et al., 2017). Bogenhagen suggested, that mL45 is binding early during assembly. However, within this doctoral project the question should be addressed, whether the mitoribosome requires its membrane anchor to assemble, whether mtLSU submodules can still assemble in the absence of mL45 and whether the assembly of the mtSSU is independent of the membrane anchor of the mtLSU.

4.2.2.2 Loss of function of mL45

In order to answer these questions, a HEK293T mL45^{-/-} cell line kindly provided by Dr. Ricarda Richter-Dennerlein was analysed. This knock-out cell line was obtained by using the CRISPR/Cas9 technology. The underlying mutations within the mL45^{-/-} cells were investigated by applying TOPO® sequencing. BLAST search against the wildtype variant of mL45 revealed three different mutations. The gene *Mrpl45* encoding for the protein mL45 is located on the chromosomal position 17q21.2 (Zody et al., 2006) and comprises 1553 bases according to the NCBI reference sequence (NM_032351.6). Karyotype analysis of HEK293T cells unveiled in most cases a triplicate of chromosome 17 (Stepanenko and Dmitrenko, 2015; Stepanenko et al., 2015). Hence, all three *Mrpl45* gene copies were affected in the present knock-out cell line. For allele 1, a deletion of 27 bp in frame was found. According to this, a truncated version of the protein, missing 9 amino acids, is built. Allele 2 is altered by a 4 bp deletion, leading to a frameshift, an altered amino acid sequence and a premature stop codon. Within allele 3, 2 bp were missing, having similar consequences as the mutation in allele 2.

Figure 35: Sequence determination of HEK293T mL45^{-/-} at the guide RNA target sequence. The sequence at the top resembles the MRPL45/mL45 wild type. Numbers indicate base positions of *Mrpl45* open reading frame. The guide RNA to create the knock-out is marked in red. Sequence of guide RNA: 5'-[GGGCAACGTGTACGGCCAGA]-3'. The three lower panels visualize the mutations: a) mL45_c.592_618del b) mL45_c.615_618del c) mL45_c.618_619del.

To determine the influence of ablation of mL45 on mitochondrial translation, a [³⁵S]Methionine labelling was performed. Due to the absence of the mitoribosomal anchor protein, the mitochondrial translation was completely abolished (Figure 36). To verify that this translational defect is specifically caused by loss of mL45, the knock-out cell line was rescued by transfection with pOG44 and pcDNA5/FRT/TO carrying the gene for a C-terminal FLAG-tagged wildtype variant of mL45. For selection of clones having successfully integrated mL45^{FLAG} into the Flp-In cassette, cells were treated with hygromycin. The successful established cell line called mL45^{-/-} R showed a wildtype-like phenotype, proving that deficiencies of the knock-out cell line are specifically resulting from loss of mL45.

Figure 36: Ablation of mL45 leads to mitochondrial translation deficiency. To test mitochondrial translation, cells were grown for 1 h in media containing [³⁵S]Methionine. Simultaneously, cytosolic translation was blocked with emetine. De novo synthesized mtDNA-encoded proteins were detected by autoradiography (upper panel). Samples (50 µg) were analysed by SDS-PAGE and immunoblotting (lower panel). GAPDH was used as loading control. Asterisk indicates unspecific antibody binding due to usage of homemade mL45 antibody. Cells were induced with 100 ng/µl tetracycline for 24 h prior labelling (n = 3).

Besides the translation defect, cells lacking mL45 showed also reduced steady state levels of various MRPs (Figure 37). Some proteins of the 39S mtLSU were slightly reduced (uL1m, bL20m, bL21m, mL39). Protein levels of others were stronger affected (uL3m, uL23m, mL44, mL62) and uL13m was completely lost. As mentioned in section 4.2.1, the mtLSU protein uL13m was also depleted in the mL44^{-/-} cell line (Figure 29A) and was one of the less stable proteins during actinonin treatment (Figure 32A). Therefore, it is not surprising that uL13m is not detectable in mL45^{-/-} cells, as it seems to be one of the least stable proteins. As suggested in 4.2.1, bL20m and bL21m are building a complex together with mL44. Thus, it seems reasonable, that bL20m and bL21m were stronger affected by depletion of mL44 than by loss of mL45. Nevertheless, steady state levels of some proteins were not affected (uL10m, bL12m) probably for the same reason as in mL44 deficient cells.

The 28S mtSSU protein levels compared to a WT control of uS14m (11 %), uS15m (56%), mS22 (40 %) and mS25 (36 %) were stronger reduced in mL45^{-/-} cells (Figure 37B) than in cells lacking mL44 (uS14m: 14 %, uS15m: 88 %, mS22: 63 %, mS25: 59 %), suggesting that loss of mL45 has a more severe impact on the complete mitoribosome. The uS7m and mS27 protein levels were not affected.

Most of the tested assembly factors (GTPBP10, MALSU1, NSUN4) were diminished upon loss of mL45 (Figure 37B).

Figure 37: Analysis of protein steady state levels of cell lysates from HEK293T WT, mL45^{-/-} or mL45^{-/-}R. Cells were treated for 24 h with 100 ng/μl tetracycline prior analysis. A and B) Samples (50 μg) were tested by immunoblotting using antibodies against MRPs of the mtLSU, mtSSU and of assembly factors (AF). C) Protein levels of mL45^{-/-} cell line were quantified using the software ImageQuant TL and calculated relative to wild type (WT). Calnexin served as loading control (n=3, mean ± SEM). mL45 antibody used during this experiment: ProteinTech (15682-1-AP). Asterisks indicates residual signals from previous antibody decorations.

To determine whether mitoribosomal particles or subcomplexes are formed in absence of mL45, lysates from mitoplast preparations from HEK293T WT, mL45^{-/-}, mL45^{-/-}R were subjected to sucrose gradient ultracentrifugation. Upon loss of mL45, no 39S mtLSU and no monosome was present (Figure 38A). Although a similar profile of tested mtSSU proteins in sucrose gradients compared to WT samples was observed (Figure 38B, C), steady state levels were in some cases severely reduced (Figure 37B, C). These data suggest that 28S mtSSU assembly is in some degree affected by the loss of mL45. All tested assembly factors accumulate in the lower dense fractions if mL45 is missing (Figure 38D).

Figure 38: Impact of loss of mL45 on mitoribosome assembly. Mitoplasts (500 μ g) obtained from HEK293T WT, mL45^{-/-} or mL45^{-/-} R were lysed and ribosomal particles were separated via sucrose density gradient centrifugation. A, B, D) Fractions were analysed via SDS-PAGE and western blotting using indicated antibodies. C, E) Selected markers for mtSSU (uS14m) and mtLSU (bL20m) were quantified by using the software ImageJ and plotted relative to the total protein level across the gradient. M = 10 μ g HEK293T WT mitochondria, 10 % Input of loaded material = 50 μ g mitoplast lysate (n = 3).

As there is neither a 39S mtLSU particle nor an assembly intermediate close to its density built, proteins of the mtLSU accumulate in the lower dense fractions (Figure 38A, E). Thus, mL45 needs to be incorporated early during mitoribosome biogenesis and its loss prevents further 39S assembly. As already described in section 4.2.1, there are different sedimentation profiles in these early fractions for distinct assembly intermediates. As the proteins bL20m and mL44 were not

found to be in a complex together with mL45 (Figure 31C), their accumulation upon mL45 ablation suggests that this submodule can be formed and is also stable if the mitochondrial membrane anchor is missing. In addition, the subcomplex in fraction two and three containing uL23m remained stable in absence of mL45. The sedimentation profile of uL1m, bL12m, bL32m, mL39 and mL62 looked similar to the one of mL45 in the first three fractions of the gradient. By taking the structural information of the localisation of those proteins into consideration, uL1m, bL12m and mL62 are very unlikely to build a subcomplex together with mL45.

4.2.2.3 Interactome of mL45

To determine the composition of mL45 complexes, FLAG-immunoprecipitation experiments were performed followed by sucrose gradient centrifugation. In initial experiments, the HEK293T mL45^{FLAG} cell line was used. Using mL45^{FLAG} as a bait, proteins of the mtLSU and mtSSU were co-purified. This indicates that mL45^{FLAG} is functional and able to be incorporated into the 39S mtLSU, which can form 55S particles (Figure 39). Some proteins were more enriched in the elution fraction than others. The L7/L12 stalk protein bL12m co-immunoprecipitated with mL45^{FLAG} in lower portions whereas the central protuberance protein mL62 was enriched in the elution fraction.

Figure 39: mL45^{FLAG} immunoprecipitation Isolated mitochondria (1 mg) from HEK293T WT (negative control) or mL45^{FLAG} cells were lysed and subjected to FLAG co-immunoprecipitation. Samples were analysed by SDS-PAGE followed by immunoblotting using the indicated antibodies. SDHA served as negative control to exclude unspecific binding during immunoprecipitation. Total = 3 %, Eluate = 100 %, (n = 3). Cells were induced with 0.25 µg/ml tetracycline for 24 h prior analysis.

However, under these conditions mL45^{FLAG} was strongly overexpressed. Therefore, the HEK293T mL45^{-/-R} cell line was used in subsequent analyses, to obtain physiological levels of mL45^{FLAG} expression. By analysing fractions after FLAG-co-immunoprecipitations of mL45^{-/-R} followed by sucrose gradient centrifugation, signals from proteins corresponding to the 39S and 55S particles were observed (Figure 40). Despite that the sedimentation profiles in mitoplast gradients (Figure 38A) looked similar for bL32m and mL62 to the one of mL45, no signals in the first fractions

corresponding to an assembly intermediate were observed. Just mL39 was found in a complex with mL45 in fraction one and two. Surprisingly, uL23m and uL24m were also not present in this complex, despite the fact that inter-protein crosslinks for these proteins to mL45 were reported (Greber et al., 2014b) and that they are closely localised to mL45 (Bieri et al., 2018). These data indicate that mL45 forms a submodule together with mL39.

Figure 40: Separation of mL45^{FLAG} containing particles by sucrose density centrifugation. HEK293T mL45^{-/-R} cells were induced with 100 ng/ml tetracycline for 24 h prior mitochondria isolation. Mitochondria (2.4 mg) were lysed and subjected to FLAG-immunoprecipitation followed by sucrose gradient centrifugation. Fractions were ethanol precipitated and analysed by SDS-PAGE followed by western blotting using the indicated antibodies of mtLSU and mtSSU. Total = 1 % of FLAG-IP input, Eluate = 20 % of FLAG-IP eluate (n=1). Asterisk indicates residual signals from previous antibody decorations.

4.2.2.4 Discussion mL45

Recently, new insights about the function of the N-terminal domain (NTD) of mL45 became available. The NTD of mL45 comprises approximately 80 amino acids, reaches from L38 to N115 and is present basically in its primary structure (Kummer et al., 2018). Kummer et al. illustrated by high-resolution structural analyses that during translation initiation, the polypeptide exit tunnel is blocked by residue 38 – 64 of the NTD of mL45 and concluded that it has to be removed to enable synthesis of the nascent peptide chain. In addition, mutational analyses revealed that the NTD is necessary for functional mt translation. However, knock-out of mL45 only led to reduced mt translation.

Koripella et al. (2020) suggested, based on their latest cryo-EM structure of the 55S mitoribosome, that an adenine residue (A2725) of the 16S rRNA located between helices 73 and 74 could mediate the interaction of the nascent polypeptide chain and R40 of the NTD of mL45. By comparing structures of the initiation and elongation complex, they observed a conformational change of R61 – D73 within mL45, which they hypothesized as preparative steps for removal of the NTD of mL45 from the polypeptide exit tunnel. Furthermore, the authors were able to show another conformational change of residues T101 - Y128. The positively charged residues within this area were suggested to mediate the contact of the 55S mitoribosome to the negatively charged IMM (Englmeier et al., 2017). For this reason, charged amino acids in the segment spanning from 118 – 136 of mL45 were exchanged for alanine in a study of Mai (2016) but did not prevent binding of mL45 to the IMM. Deletion of residue 1 – 117 of mL45 described in the same study, did not inhibit anchoring of the mitoribosome to the IMM, as well. However, Koripella et al. proposed that the conformational change of T101 - Y128 of mL45 is required to anchor the mitoribosome to the IMM. In contrast, earlier publications stated that the mitoribosome interacts with the IMM independently of a nascent chain (Greber et al., 2014b; Liu and Spremulli, 2000). This arises the question, whether the mitoribosome is only anchored to the IMM during translation elongation, which would be surprising.

Ablation of mL45 led to a complete loss of assembled mtLSU and subsequently to depletion of 55S mitoribosomes (Figure 38). In contrast, mtSSU assembly was just partially affected due to ablation of mL45. Thus, it is tempting to speculate that membrane attachment of the mtLSU during biogenesis is crucial as the absence of the membrane anchor mL45 is leading to severe defects. To exclude effects based on the loss of mL45 in regard of integrity of the mitoribosomal structure, mutational analyses of the residues T101 – Y128 of mL45 would be required. This would clarify as well, under which circumstances the mtLSU is anchored to the IMM.

Within this doctoral study, it was shown that mL45 is required for mt translation and stability of most MRPs (Figure 36, Figure 37). Upon mL45 ablation, we observed a complete loss of mtDNA-encoded proteins, which is in contrast to previously published data by Kummer et al., 2018. As the authors did not perform FACS sorting after CRISPR/Cas9 transformation, cells probably represent a mixed population of mL45 mutants and wild type cells leading to an incomplete depletion and subsequently just to a reduced mt translation. siRNA mediated depletion analyses of mL45 carried out by the research group of Prof. Dr. Antoni Barrientos revealed similar tendencies in protein steady state levels (Kim and Barrientos, 2018) in comparison to the data shown here. Most of the tested mtLSU proteins were either diminished (uL14m, bL19m, mL66) or lost (uL16m) (Kim and Barrientos, 2018). Just bL12m remained stable, as well as bL36m (Kim and Barrientos, 2018). However, within a study of the same laboratory, siRNA mediated depletion of mL45 led to a severe reduction of bL36m levels (Maiti et al., 2018), which one would expect as bL36m is incorporated late during assembly (Brown et al., 2017). Nevertheless, it is not finally solved whether mL45 depletion has an influence on bL36m. bL12m was also stable in mL45^{-/-} cells (Figure 37A), probably due to additional functions of this protein on transcription regulation within mitochondria (Nouws et al., 2016; Surovtseva et al., 2011; Wang et al., 2007). By siRNA mediated depletion of mL45 no effect on the mtSSU proteins bS18m, mS27 and mS40 was observed, but a reduction of protein levels of the assembly factors MALSU1, GTPBP5, GTPBP7 and GTPBP10 (Kim and Barrientos, 2018; Maiti et al., 2018). This is in agreement with data of this study, in which a decrease of protein steady state levels of GTPBP10, MALSU1 and NSUN4 was observed as well (Figure 37B). The biogenesis factors might be less stable upon loss of mL45 as they are interacting with the mtLSU at a later assembly stage, which is not reached if mL45 is missing.

Most of the tested proteins of the mtSSU (uS14m, uS15m, mS22, mS25) in mL45^{-/-} revealed reduced steady state levels implying a cross talk between mtLSU and mtSSU. As the 28S mtSSU is not as strongly affected upon loss of mL45 as the 39S mtLSU, the effect of siRNA-mediated depletion of mL45 might not be severe enough to reveal these changes.

Bogenhagen et al., 2018, already suggested that mL45 is binding early during assembly to mediate the IMM contact. The authors described mL45 in an early assembly intermediate together with uL3m, uL14m, bL17m, bL19m, uL22m, bL32m and mL39. Our data also provide evidence, that mL45 is assembling early during mtLSU biogenesis. However, data of this thesis did not show a complex of mL45 together with bL32m in the light dense fractions after separation of ribosomal particles from FLAG co-immunoprecipitated samples or any other indication that bL32m may assemble early in this process (Figure 40). This is not surprising as the yeast homologue bL32m is assembled at a late stage (Nolden et al., 2005; Zeng et al., 2018) and its bacterial counterpart

bL32 was found to bind at an intermediate assembly step (Chen and Williamson, 2013). Consequently, it is suggested that bL32m is not binding to an early assembled submodule containing mL45.

However, mL39 was present in fraction one and two from FLAG-immunoprecipitated samples, subjected to sucrose gradient centrifugation, leading to the assumption of a module containing mL45 and mL39, which is supported by inter-protein crosslinking data between mL39 and mL45 from Greber et al. (2014b). Inter-protein crosslinks were also obtained for mL45 to uL23m and uL24m (Greber et al., 2014b), but these proteins were not detected in the submodule consisting of mL39 and mL45. Thus, uL23m and uL24m might assemble in a distinct subcomplex despite their close proximity to mL45.

The 54S yeast mtLSU proteins mL43, mL44, mL50, mL57, mL58, which are located in close proximity to the exit tunnel and which form a “membrane-facing protuberance”, assemble early during biogenesis in order to tether the growing ribosomal particle to the IMM (Zeng et al., 2018). The yeast mitoribosome is anchored to the IMM via two contact sites: the 21S rRNA segment 96-ES1 and the IMM ribosome receptor protein Mba1, which is interacting with proteins of a so called “membrane-facing protuberance” (Pfeffer et al., 2015; Zeng et al., 2018). As already mentioned, the structural homologue of Mba1 in human mitochondria is mL45 (Greber and Ban, 2016). As mL45 is the only anchor of the 55S mitoribosome to the IMM, one can hypothesize that it has to be assembled early during mitoribosome biogenesis in order to provide a platform for 39S mtLSU assembly as suggested for the biogenesis of the yeast mtLSU (Zeng et al., 2018).

5. Discussion

By using a quantitative mass spectrometry approach, Chen and Williamson, 2013, proposed an *in vivo* assembly map for the bacterial 70S ribosome. Proteins of the 50S subunit bind during the whole subunit biogenesis at every domain of the 23S rRNA (Chen and Williamson, 2013). The first group of proteins (L20, L21, L22, L24) is binding directly to the 5' domain of the 23S rRNA. Also, the second (L1, L3, L4, L13, L15, L17, L23) and third group (L5, L18, L29, L34) are binding mostly immediate to the rRNA. The fourth group of binding proteins consists of L14 (binds to the rRNA) and L2, L19, L32 (bind to already present proteins). Within the fifth group are L6, L9, L11, L28 and L33 assembling onto the 23S rRNA and at last L7/L12, L10, L16, L25, L27, L30, L31, L35 and L36 are incorporated to finish the LSU assembly (Figure 41) (Chen and Williamson, 2013).

Figure 41: Assembly of the bacterial 50S LSU and the *S. cerevisiae* 54S mtLSU. Proteins of the yeast mtLSU, which are conserved in bacteria are shown in black, while mitochondrial ribosome specific proteins are visualized in blue. Known assembly factors of the 54S particle are depicted in grey and their bacterial orthologs/paralogs are shown on the bottom of the *E. coli* panel. Picture adapted from Zeng et al., 2018. Reprinted from *Cell Metabolism*, 27, Zeng, R., Smith, E., and Barrientos, A.: Mitoribosome Large Subunit Assembly Proceeds by Hierarchical Incorporation of Protein Clusters and Modules on the Inner Membrane. 645-656, Copyright (2018), with permission from Elsevier. DOI: <https://doi.org/10.1016/j.cmet.2018.01.012>

Upon loss of various assembly factors, biogenesis of the bacterial LSU was trapped, leading to late assembly intermediates (Jomaa et al., 2014; Li et al., 2013; Ni et al., 2016). Structural analyses of these immature particles revealed predominantly a lack of assembled central protuberance (CP) consistent with the mainly late incorporation of CP proteins (L5, L16, L18, L25, L27, L31, L33, L35) into the LSU (Davis and Williamson, 2017; Korepanov et al., 2012). Interestingly, the peptidyl transferase centre was also in an immature assembly stage, giving rise to the hypothesis of a very late maturation of this catalytical core (Davis and Williamson, 2017).

In contrast to the bacterial ribosome, mitoribosomes of different species consist of an increased number of proteins but variable rRNA contents (Figure 42). Despite their tremendous structural differences, the assembly mechanisms are hypothesized to follow basically a similar path (Jaskolowski et al., 2020).

Figure 42 Comparison of RNA:protein ratios of different species (Jaskolowski et al., 2020). Blue = RNA, orange = protein.

Like for the assembly of the bacterial ribosome, a stepwise incorporation of protein modules was described for the 54S yeast mtLSU (Figure 41) (Zeng et al., 2018). Proteins having homologs in bacteria, are incorporated at comparable stages during biogenesis.

The CP in yeast was remodelled during evolution due to the absence of an additional structural RNA component (Amunts et al., 2014). Box et al. (2017) suggested the existence of a subcomplex consisting of proteins of the CP (mL38, uL5, bL27, mL46, mL40). Within mutational analyses of Zeng et al. (2018), CP proteins remained stable, proposing that they form an independent protein complex, which is incorporated into the growing mtLSU. Recent studies of the biogenesis of the mtLSU of *Trypanosoma brucei* implicated the presence of a pre-assembled CP as well (Jaskolowski et al., 2020). On the contrary, Bogenhagen et al. (2018) described proteins forming the CP (Figure 43) to be incorporated at an early (mL40, mL46, mL48, bL31m) or intermediate (uL18m, bL27m, mL38, mL62) assembly stage.

The mtLSU MRP mL62 was detected in fraction one and two from sucrose gradients of mitoplast lysates from HEK293T WT cells (Figure 30). mL62 was previously described to be incorporated late during mtLSU biogenesis (Richter, 2010). It would be one possibility that mL62 along with other proteins of the CP and the structural tRNA^{Val} forms a subcomplex similar to the ones observed in *S. cerevisiae* and *T. brucei*, which can be detected in light dense fractions of a sucrose density gradient. However, mL62 also belongs to the release factor family and might be involved in translation termination and ribosome rescue pathways (Akabane et al., 2014; Richter et al., 2010), like its bacterial homologue ArfB (alternative ribosome-rescue factor B), which was just recently reported to rescue stalled ribosomes (Chan et al., 2020). Thus, mL62 in fractions one and

two might represent different populations e.g. a free pool available from ribosome rescue or a submodule of the CP, respectively. To dissect this hypothesis, immunoprecipitation experiments of mL62 followed by sucrose gradient centrifugation would be necessary to analyse the composition and existence of a subcomplex present in fraction one and two.

Figure 43: Protein interactions within 39S mtLSU. Black lines indicate conserved interactions from the bacterial ancestor, whereas red lines represent mitochondrion specific connections. blue = proteins having homologs in bacteria, red = mitochondrial ribosome specific proteins. ICT1 = mL62, CRIF1 = mL64. Encircled are proteins of L7/L12 stalk and central protuberance. Due to the high flexibility of the L7/L12 stalk, bL12m was not modelled. Picture adapted from Brown, A., Amunts, A., Bai, X. -c. X.-C.C., Sugimoto, Y., Edwards, P.C., Murshudov, G., Scheres, S.H.W.W., and Ramakrishnan, V. (2014). Structure of the large ribosomal subunit from human mitochondria. *Science* (80). 346, 718–722. Reprinted with permission from AAAS. DOI: <https://doi.org/10.1126/science.1258026>

Based on a cryo-EM analysis of another late stage assembly intermediate from *T. brucei*, assembly of the L7/L12 stalk is suggested to happen late during mtLSU biogenesis (Tobiasson et al., 2020). The authors identified an assembly intermediate lacking the CP and the L7/L12 stalk. Instead, a total of 16 assembly factors were found to be associated. Thus, a model was proposed where dissociation of assembly factors enables rRNA folding, conformational changes and at last binding of uL10m and four copies of bL12m. Also in the yeast mtLSU, uL10m and bL12m are incorporated late similar to homologs in bacteria (Chen and Williamson, 2013; Zeng et al., 2018). However, within the assembly map of the human mtLSU uL10m and bL12m are designated early binding proteins (Bogenhagen et al., 2018), which is in discrepancy to the bacterial, yeast and trypanosomal mtLSU assembly.

Data of this doctoral study show comparable sedimentation profiles for uL10m and bL12m in sucrose gradients (Figure 30). In addition, uL10m and bL12m are stable upon ablation of the early

binding proteins mL44 and mL45 (Figure 29, Figure 37), leading to the assumption that proteins of the L7/L12 stalk might form an independent subcomplex as described for the CP of *S. cerevisiae* and *T. brucei*, which is incorporated at a late biogenesis stage (Jaskolowski et al., 2020; Zeng et al., 2018). This pre-assembled submodule could be detectable in the light dense fractions of sucrose gradients. Similar approaches as mentioned to dissect the submodule containing mL62 would be required to investigate the existence and composition of the complex containing uL10m and bL12m and would shed light into the biogenesis of the L7/L12 stalk.

The 39S human mtLSU consists of 52 proteins. Out of these, there are 30 proteins having homologs in bacteria whereas 22 are mitoribosomal specific. Three proteins (uL5, uL6, bL25) are existing in the bacterial 50S LSU but not in the 39S mtLSU (Ban et al., 2014; Greber and Ban, 2016). Even if the mitoribosomal proteins conserved in bacteria are following a comparable assembly path, the order of incorporation of the mito-specific proteins remains not completely solved. Based on the observations of the biogenesis of the mtLSU of *T. brucei* it was proposed that ribosomes with a high protein content assemble at first their “protein shell” at an early stage, probably independent from rRNA maturation steps (Jaskolowski et al., 2020). Data of this doctoral thesis support this theory as the mitochondrial ribosome specific protein mL44, which is located on the surface of the mtLSU particle, is assumed to be assembled with bL20m, bL21m, mL42, mL43 and mL50 early during biogenesis. By using a SILAC approach containing purified mitoribosomes, we want to address this issue further. The future analysis of these data will give intriguing new insights into the assembly of the 39S mtLSU and will enable us to understand the order of incorporation of mitoribosomal specific proteins in the background of assembly maps of other species.

7. Supplementary

Supp. Figure 1: Localisation of 55S monosome in a 10-30% sucrose gradient (A) and 5-30% sucrose gradient (B). LFQ intensities for two specific mtLSU (mL44) and mtSSU (mS27) proteins were plotted over the gradient fractions.

Supp. Figure 2: Quantification of protein levels after actinonin treatment (150 μ M). Mean of protein levels of mtLSU, mtSSU and AF relative to control (GAPDH) was plotted over time (n=3).

Supp. Table 1: MS-analysis of fraction 9 from a 10-30% sucrose gradient (lysate of mitochondria was separated). Mitoribosomal proteins are coloured in green, whereas cytosolic ribosomal proteins are visualized in grey.

8. Acknowledgements

At first, I want to thank Dr. Ricarda Richter-Dennerlein who provided me with the opportunity to work on this interesting project. Thank you for your great supervision, your advices regarding lab work, data presentation and writing and for your motivation when I struggled during mitoribosome isolations.

Next, I owe many thanks to the members of my thesis advisory committee: Prof. Dr. Marina Rodnina and Prof. Dr. Blanche Schwappach. Thank you for all your good suggestions and the challenging discussions during my thesis advisory committee meetings, which helped me to improve my scientific work. Especially, I also want to thank Prof. Dr. Heike Krebber for being my new second referee due to Prof. Dr. Schwappachs movement to Hamburg. In addition, I owe many thanks to Prof. Dr. Michael Meinecke, Prof. Dr. Ralph Kehlenbach and Prof. Dr. Henning Urlaub for agreeing to be in my extended examination board.

I thank Prof. Dr. Marina Rodnina for sharing her expert knowledge and her advice during establishing sucrose gradients and ribosome isolation protocols. Furthermore, I want to thank Dr. Ekaterina Samatova for helpful discussions and Sandra Kappler for giving me hands-on experience in ribosome purification procedures.

I owe many thanks to our collaborators Prof. Dr. Henning Urlaub and Dr. Andreas Linden for MS-analysis of my samples. Additionally, I thank Monika Raabe and Uwe Pleßmann for sample preparation prior mass spectrometry. I want to thank Lukas Schulte and Uma Lakshmi Dakshinamoorthy for their help to figure out the perfect sucrose concentration for mitoribosome isolations.

I would like to thank the GGNB and the SFB860 for providing support during my pregnancy. In addition, I would like to thank the GGNB office for their constant help regarding questions of the doctoral program. I owe many thanks for practical support during my pregnancy and maternity leave to Anna Teegen and Joana Oschwald. Thank you for casting uncountable gels for me. I could not have managed without you.

Many big thanks are going to all members of the research group of Dr. Ricarda Richter-Dennerlein. Especially, I want to thank Elena Lavdovskaia for helpful discussions and Mandy Mai, Franziska Nadler and Emely Steube for their help during ribosome isolation! Also, I am thankful to Dr. Cong Wang and Dr. Sven Dennerlein for many advices during the last years. I thank Amanda Ernst for proofreading this thesis. Last but not least, I want to thank my family for their constant support during my whole life and for taking care of Rosa, which enabled me to write this thesis. Stefan, thank you for always being there for me and Rosa for being the joy of my life! This thesis would not have been possible without you!

Profile

Born in 1990
in Lutherstadt Wittenberg

Name at birth: Kolander

Married, one daughter

Education

PhD Student

University Medical Center - Göttingen, Institute for Cellular
Biochemistry, Supervisor: Dr. Ricarda Richter-Dennerlein

10/2016 – 11/2020

Master Molecular Medicine

Georg-August-University Göttingen,
Degree: Master of Science (1.46)

10/2014 – 04/2016

Bachelor Biotechnology

Ernst-Abbe-Hochschule Jena,
Degree: Bachelor of Engineering (1.3)

10/2011 – 07/2014

Medical studies

Martin-Luther-University Halle-Wittenberg,
Degree: Preliminary medical examination

2008 – 2011

A-level

Europagymnasium „Walther Rathenau“ Bitterfeld-Wolfen.
Grade: 1.4

2002 – 2008
